glycophorin A^N, despite the fact that this peptide was obtained from glycophorin B isolated from pooled blood of many individuals. Also, the threonine and serine residues glycosylated in glycophorin A were found to be glycosylated in exactly the same positions within the first 25 amino acid residues. B-T2 contains one asparagine or aspartic acid. The lack of glycosylation at this position could be explained either by finding only aspartic acid in this position or by the drastic change in amino acid sequence C-terminal of residue 26, which is entirely different from the corresponding region of glycophorin A. N-glycosylation as far as known invariably occurs at asparaginyl residues in the sequence Asn-X-Thr (or Ser) (ref. 25). On occasion we found serine in addition to threonine in position 12. Since the residue in this position is glycosylated, only dansylation detects an amino acid. The lack of quantitation does not allow us to decide whether serine is the only amino acid residue at this position.

Serological MN activity correlated with amino terminal structure of glycoproteins

As indicated earlier, many laboratories have reported the presence of N-activity on *MM* homozygous cells^{5,7,10}, and this finding is one of the crucial elements for a hypothesis that the N-blood group substance represents the precursor for M⁷. We therefore studied the blood group activities which are associated with these proteins, isolated from individuals which are classified according to the two allele model into *MM*, *MN* and *NN*. First attempts focused on the activities of glycophorin A and glycophorin B preparations isolated as described above. A^N and B^N did not inhibit the agglutination of *MM* erythrocytes, but B^M inhibited the agglutination of *NN* erythrocytes, suggesting that *MM* homozygotes contain N activity in one of the minor sialoglycoproteins as previously suggested⁴. However, the difference between the activity of B^M in inhibiting *MM*- and *NN*-agglutination was only 3–4-fold, suggesting that B^M is contaminated with A^M, for which our chemical studies provided sufficient support.

In view of the difficulties in isolating pure glycophorin B, we analysed the serological activities of the tryptic glycopeptides which can be purified and characterised more readily. In Table 2 the data obtained by a semiquantitative haemagglutination-inhibition assay are summarised and the results can be stated as follows: the total glycophorin fraction, glycophorin A and the N-terminal peptides isolated from glycophorin A inhibit the homologous agglutinating system, but not the heterologous system; that is, peptides isolated from *M* homozygotes inhibit only the agglutination of *MM* cells, but not of *NN* cells. Peptides prepared from glycophorin A^{MN} are equally active in both systems; only the amino terminal glycopeptides are active, but not the only other glycopeptide T3A derived from glycophorin A, which is also located at the exterior of the cell^{12,14}; peptides T1 and T2 are equally active, but are 2–4-fold less active than glycophorin A,

Table 2 Serological activity of sialoglycopeptides isolated from glycophorin A and glycophorin B in individuals homozygous or heterozygous at the *MN* locus

Inhibitors	Haemagglutinin-inhibition of inhibitors*

Sialoglycoproteins and glycopeptides were assayed by a semi-quantitative haemagglutination-inhibition assay. One drop each of serum appropriately diluted (four agglutinating units) was incubated with one drop of a serial dilution of inhibitor for 3 min, before one drop of a 5% erythrocyte suspension in phosphate buffered saline was added. The plates were shaken at room temperature and were scored after 10 min. The protein concentration of the inhibitors was determined by amino acid analysis using norleucine as internal standard.

*Concentration of inhibitors in nmol ml⁻¹ completely inhibiting four agglutinating units. n.t. not tested.

†Sera obtained from Ortho, Lot No. M 127, M 173, and N 157.

‡MM, MN, and NN refer to the serological blood type of the red cell membranes, which were used to isolate the total sialoglycoprotein fraction, glycophorin A (A^M or A^N) or glycophorin B (B) by methods described elsewhere^{20,21}. Tryptic sialoglycopeptides T1, T2, T3A were prepared from glycophorin A or glycophorin B (A-T1 etc., B-T2 etc.)

§Single donors.

||Pooled blood from two donors.

¶Pooled blood from about 25 donors.

which is about 1.5- to 3-fold less active than the unseparated mixture of sialoglycoproteins; only the amino terminal peptide B-T2 of glycophorin B shows activity and this activity is restricted to *N*. The starting material for the isolation of peptide B-T2, glycophorin B, has activity for *M* and *N*, consistent with the phenotype of the original cells from which it has been isolated and assuming that glycophorin A is present in this fraction as a contaminant.

Genetic variants which lack glycophorin A

In Table 3 sialoglycoprotein profiles of membranes from some variant cells are calculated from SDS-polyacrylamide gels²⁶ in comparison with normal cells. The cells we have used are either homozygous or heterozygous at the major *MN*-locus and according to serological data express either no *MN* activity or only half the amount³. On the basis of this analysis, several cell types can be distinguished: heterozygous *M^NN* cells which serologically express only *N*, but no *M* activity, are indistinguishable from normal cells; heterozygous *M^kM* cells³, which serologically express only half the activity of *MN* and *Ss* antigens, have only 50% PAS-stainable protein as compared to normal cells, affecting both glycophorin A and B; cells from two individuals designated *En(a-)* G. W. (Finland) and *En(a-)* E. H. (England) are indistinguishable from each other and show a reduction of the total stainable glycoprotein of about 80%, mostly accounted for by loss of glycophorin A stainability; cells with *Tn* phenotype^{3,28,42} again show about 80% reduction of stainable glycoproteins, which affects both glycophorin A and B. Although these results are in general agreement with serological results (with the exception of *En(a-)* E. H. (refs 30, 40)) and with the finding of others, several problems inherent in this technique should be pointed out.

Tanner and Anstee⁹ first suggested that the major sialoglycoprotein is absent in *En(a-)* cells. Dahr and colleagues in a series of papers concluded from their analysis of gel electrophoretic data (similar to ours) in conjunction with serological results that the serological abnormalities observed in these and other variant cells are correlated with the partial or total absence of one or more of the cell membrane sialoglycoproteins^{10,29,30}. Gahmberg *et al.*¹¹, in a more careful analysis of cells with *En(a-)* phenotype, used various radioactive probes to detect cell surface alterations and arrived at similar conclusions. These data, however, left some doubt, since absence of sialic acid and/or galactose from the glycoproteins would result in loss of just the structures which are required for detection by the techniques used. The attempt to label radioactively the protein backbone of glycophorin A and B by iodination gave equally ambiguous results, since glycophorin B could not be labelled in *En(a-)* cells despite the fact that this protein is labelled in normal cells and was found to be present in these cells by other techniques¹¹. In addition, the interpretation of data obtained by SDS-polyacrylamide gel electrophoresis is complicated by the lack or incomplete separation of glycophorin A and B from each other and other undefined glycoproteins^{21-24,26}, and is not entirely resolved by the use of other electrophoresis systems^{23,27}. Also these proteins tend to aggregate and to migrate electrophoretically at several positions, making quantitation difficult.

In order to overcome these problems we have developed a simple radioimmunoassay procedure which uses rabbit antibodies specific for a C-terminal determinant of glycophorin A. Since these antibodies react with the protein portion of glycophorin A exclusively, post-translational modification of the proteins on the N-terminal segment (which apparently is required for the expression of *MN* activity) or absence of glycosylation should not affect the assay. By using this assay the amount of glycophorin A for normal, unmodified human erythrocyte membranes was determined as 1.6% of the total membrane protein. Removal of sialic acid does not affect the results. Since the reaction of antibodies with glycophorin A can be specifically inhibited by small C-terminal peptides derived from glycophorin A (ref. 17 and unpublished results) and as membranes prepared from erythrocytes of other species, like guinea pig, sheep, or rat do not inhibit binding, no other membrane proteins seem to react or cross-react. Only chimpanzee cells were found to be reactive and contain about the same amount of glycophorin A or an analogue (unpublished) in accordance with the expression of *MN* activity in these cells³¹. When the variant cells listed in Table 3 were analysed in addition to membranes from one individual of the Finnish family heterozygous for *En(a-)*, the results shown in Fig. 3 were obtained. Three groups of cells can be distinguished: cells with no detectable glycophorin A, homozygous *En(a-)* G. W. or E. H.;

Table 3 Polyacrylamide gel electrophoresis and periodic acid-Schiff (PAS) staining of red cell membrane sialoglycoproteins* in genetic variants

Source of membranes	% of control membranes		
	Glycophorin A (PAS 1 & PAS 2)	Glycophorin B (PAS 3)	Total (PAS 1, 2, 3)
<i>M^NN</i>	98.4	101.1	97.2
<i>M^kM</i> (H.S.)	58.8	49.1	57.8
<i>M^kM</i> (F.Q.)	58.2	43.5	56.6
<i>En(a-)</i> (G.W.)	10.9	73	18.6
<i>En(a-)</i> (E.H.)	14.1	76.6	21.2
<i>Tn</i>	19.4	21	19.6

*Membranes were prepared by standard procedures³⁶ and dissolved immediately in buffer containing 5% sodium dodecyl sulphate. After incubation for 30 min at 37 °C the samples were applied to 5.6% polyacrylamide gels²⁶ and run until the tracking dye reached 8 cm. The gels were fixed, stained with PAS reagent, and scanned at 560 nm in 0.1% Na₂S₂O₅ in 0.01 N HCl. The peak areas were calculated by triangulation and normalised to equal protein loads. The data from three determinations obtained for variant cells are given in per cent as compared to normal cells for glycophorin A (PAS 1 and 2)²¹, glycophorin B (PAS 3)²¹, and total PAS-stainable protein recovered. For explanation of the variant cells see text.

Fig. 3 Analysis of variants at the *MN* locus by quantitative radioimmunoassay-inhibition. Erythrocyte membranes from normal or variant cells (freshly prepared or kept frozen at -70°C) were dissolved in phosphate buffered saline, containing 0.02% NaN_3 and 0.15% Ammonyx-LO (lauryl dimethyl ammonium oxide) and were used in a radioimmuno-inhibition assay as described previously¹⁷. The protein concentration of the inhibitors was determined by amino acid analysis using norleucine as an internal standard or by the Lowry procedure with bovine serum albumin as the standard. Erythrocyte membranes from individuals with genotype M^kN (\square), M^kM (H.S. \bullet , F.Q. \blacksquare), $En(a-)$ homozygous (G.S. or E.H. \times) and two control individuals (\square , \triangle). *Tn* cells were indistinguishable from normal controls and $En(a-)$ heterozygous cells were identical to M^kM cells in this assay.

cells which contain 50% glycophorin A in comparison to normal, M^k heterozygotes or $En(a-)$ heterozygotes (not shown); and cells which are indistinguishable from normal controls, M^k heterozygotes or *Tn* cells (not shown).

Conclusions and perspectives

The *MNSs* locus determines two proteins, glycophorin A and glycophorin B, which are structurally related. The two alleles *M* and *N* determine a difference in amino acid sequence of glycophorin A, but this difference is restricted to two positions only. Serine and glycine are found in positions 1 and 5 of the amino acid sequence in glycophorin A^M and leucine and glutamic acid replace these amino acids in the corresponding positions in glycophorin A^N. This finding explains the heterogeneity previously observed in these two positions of the amino acid sequence of glycophorin A^{12,14,15}. Glycophorin B probably carries the antigenic determinant(s) which distinguish two allelic forms *S* and *s*, and was found to be identical in sequence with A^N in at least the first 23 residues regardless of the *MNSs* type of the cell membranes, from which the protein has been isolated. As the amino terminal peptide from glycophorin B reacts equally well with antibodies to glycophorin A^N, we conclude that the serological distinction between A^M and A^N resides within the amino terminal region of these proteins. This observation is consistent with the finding that red blood cells from *MM* homozygotes react with anti-*N* sera, particularly when treated with proteases, or are capable of removing antibodies from such sera in absorption experiments. The sialoglycoproteins determined by the *MNSs* locus are thus closely related, but not in the sense postulated by Springer^{7,32}, who proposed that the immunodeterminant structure of *M* and *N* is an oligosaccharide. The two structures were considered to be related since *N* was further postulated to be the biosynthetic precursor for *M*, which is generated by the addition of one sialic acid residue. According to this idea, *M* and *N* are genes which are responsible for post-translational modifications, but not structural genes as shown here. Our finding also does not favour the view that electrostatic interactions between ϵ -amino acid groups of lysine and carboxyl groups of sialic acid are important for a certain steric arrangement of the *M* and *N* specific structures³³. These ideas were based on the effects of modification of the protein by various compounds³⁴ and the changes of activity by removal of sialic acid or by amidation of the carboxyl group of sialic acid residues³⁵. The only two lysyl residues in the amino terminal glycosylated region are found in positions 18 and 30, and

glycosylation in the vicinity seems to interfere with proteolytic degradation by trypsin and chymotrypsin, probably due to steric hindrance or to certain conformational arrangements of the polypeptide backbone, which make these residues inaccessible. The lysyl residues, however, are separated by three and four amino acids, respectively, from oligosaccharide structures. Interaction between different subunits of glycophorin³⁶ could bring such residues in close proximity, but this does not seem to be likely, because small glycopeptides are only slightly less active than the intact protein in its isolated form. Alternative possibilities to explain the above findings are: a free amino group of the N-terminal serine or leucine may be important, as *M* or *N* activity can be restored after removal of the modifying groups³⁴; clustered oligosaccharides and sialic acids may impose certain restrictions to free mobility of the underlying polypeptide backbone. Removal of sialic acid could cause a change in the conformation of the protein, which is accompanied by loss of antigenic activity. It has been suggested that carbohydrates may influence or support certain protein conformations³⁷. More direct studies will be required to solve this question.

Serological studies in humans reveal abnormalities of expression of the *MNSs* antigens in certain rare instances³. Such abnormalities are correlated sometimes but not always with a considerable decrease in the amount of sialic acid associated with the plasma membrane. These observations are reminiscent of studies in mice in which strain differences in electrophoretic mobility and agglutinability are most easily explained by assuming one locus with only two alleles, *Eam*^h and *Eam*^l (ref. 38). The overall agreement between the distribution of the phenotypes in different crosses and the expectations from a simple diallelic system were sufficient to assume that one gene is of either unique or overriding importance in determining the surface charge of mouse erythrocytes. It was postulated that one gene either regulates the expression of a sialoglycoprotein directly or that it controls the quantity of a sialyl transferase.

In this study we have shown unambiguously that glycophorin A either can be totally absent from human erythrocytes or that the protein is altered so extensively that it can no longer be recognised as such; a total absence of glycophorin B is also possible²⁹, but no homozygous individual has been found (yet), who lacks both proteins. Loss of *MN* activity, however, is not necessarily associated with the absence of glycophorin A, as the two examples *Tn* and *M*^s show. For *Tn* cells a block in transfer of galactose is postulated^{28,42}. In *M*^s cells, as well as possibly in other variant forms³, the alteration seems to be much more subtle.

The absence of glycophorin A or B is not apparently associated with disease and to our knowledge no functional or other abnormalities have been described involving cell or membrane³⁹. Previous speculations on the role of various segments of these sialoglycoproteins for membrane organisation and function for the mature red cell membrane thus do not seem justified²². These cell surface molecules may be more important during earlier stages of differentiation. A genetic event involving cells committed to the erythrocytic series is expected to result in abnormal erythrocytes exclusively. We do not know when glycophorins are synthesised first and whether their synthesis is restricted to cells of the erythrocytic series. Possibly even in variant cells these proteins are made during the early phases of haematopoiesis, but are lost during later stages of differentiation. It is certain, however, that the absence of glycophorins alone does not describe all the alterations of the membrane which do occur in these variant cells and which involve other proteins and/or lipid components of the membrane¹¹.

We thank Drs Issitt, Lalezari, Leikola, Luner, Miller and Metaxas for samples of variant blood and Mr B. Proctor for technical assistance. Research support was obtained from the Anna Fuller Fund and the American Cancer Society BC-102C.

Revised estimate of gravitational radiation from Crab and Vela pulsars

PROGRESS in the development of ultra-high-Q dielectric crystals (Bagdasarov *et al.* unpublished data) has caused experimenters in the field of general relativity to look for rotation-induced gravitational radiation from pulsars (D. H. Douglass, unpublished data). If one could control the frequency of oscillation of a high-Q crystal, keeping it in phase with the electromagnetic signals observed from a pulsar, one might hope to absorb a measurable amount of (quadrupole) gravitational radiation at twice the pulsar frequency. Press and Thorne¹ in 1972 estimated that the gravitational waves from the Crab pulsar would produce a dimensionless strain in a detector on Earth of $h \sim 10^{-26}$ to 10^{-28} , and that other pulsars would be several orders of magnitude fainter. Additional observational data, and progress in pulsar models during the past five years, make a new estimate desirable. I report here that the amplitude of the gravitational waves from the Crab pulsar (PSR0531+21) is likely to be within 2 orders of magnitude of 10^{-27} , but that the Vela pulsar (PSR0833-45) is likely to produce waves of amplitude a factor 10 to 100 larger.

The waves are produced by the rotation of mass asymmetries in the neutron star. Of all conceivable mass asymmetries, conventional pulsar theory^{2,3} points to one as the most likely

to dominate the radiation: the neutron star must be rotationally flattened with oblateness $\epsilon_0 \equiv (\text{equatorial radius} - \text{polar radius})/(\text{mean radius})$. If the star were to rotate about its polar axis of symmetry, it would not radiate gravitationally. But, the observed 'restless' behaviour of the Crab and Vela rotation periods P (refs 2, 4) makes it likely⁵⁻⁸ that the rotation axis and the symmetry axis are misaligned by a small angle θ_w . Such a misalignment would produce a 'Chandler wobble' in the star's rotation⁶, and the wobble-induced strains would produce microquakes that provide an attractive and successful explanation^{5,7} for the observed 'restlessness'. The misalignment would also cause a fraction $\epsilon \equiv \epsilon_0 \theta_w$ (for small θ_w) of the star's moment of inertia I to radiate as a time-changing quadrupole moment. The resulting luminosity in gravitational quadrupole radiation would be¹

$$L_{\text{GW}} = \frac{32G}{5c^5} \epsilon^2 I^2 \left(\frac{2\pi}{P} \right)^6 \approx 5 \times 10^{32} \text{ erg s}^{-1} \left(\frac{\epsilon}{2 \times 10^{-8}} \right)^2 \left(\frac{I}{4 \times 10^{44} \text{ g cm}^2} \right)^2 \left(\frac{P}{0.033 \text{ s}} \right)^{-6}$$

Of the crucial parameters, P is determined by radio and optical observations⁴ to great precision. The distances to the pulsars are less well known, but the association with supernova remnants yields distance estimates of 2,000 pc and 500 pc for the Crab and Vela respectively, good to within about 25%^{4,9}. Neutron-star moments of inertia depend both upon the assumed mass of the star and upon the equation of state of matter at high densities. But because the stellar radius tends to decrease as mass increases, I is somewhat buffered; early equations of state² gave $7 \times 10^{43} \lesssim I \lesssim 7 \times 10^{44} \text{ g cm}^2$, but more recent work¹⁰ suggests $3 \times 10^{44} \lesssim I \lesssim 3 \times 10^{45} \text{ g cm}^2$. Within this range, the original Pines and Shaham⁵ 'crustquake' explanation of the Crab pulsar glitches agrees with the spindown power output ($I\dot{\Omega}$) required to drive the nebula^{2,11} and implies $I \sim 4 \times 10^{44} \text{ g cm}^2$ (though Pandharipande, Pines and Smith (PPS) for their 1.33 M_\odot Crab model¹⁰ find $I \sim 2 \times 10^{45} \text{ g cm}^2$). The Vela pulsar, which has experienced at least three 'giant' speedups within the past 8 yr (refs 4, 12) is modelled as a more massive, solid-core object¹⁰ with the moment of inertia¹⁰ $I \sim 2$ to $3 \times 10^{45} \text{ g cm}^2$.

The oblateness of the star, ϵ_0 , is predicted by standard star-quake theory and by calculations of the critical strain which the crust (for the Crab) or the core (for Vela) can withstand before

Table 1 Estimated pulsar gravitational radiation			
	Standard Crab	PPS ¹⁰ Crab	Vela

fracturing. The resulting values are, for the Crab^{2,6,8}, $\varepsilon_0 = (1-2) \times 10^{-4}$ (though the PPS 1.33 M_\odot model¹⁰ has $\varepsilon_0 \approx 3.5 \times 10^{-4}$), and for Vela^{8,10,13}, $\varepsilon_0 \sim 10^{-2}$ to 10^{-3} . The fraction of this oblateness which is effective in producing gravitational radiation is θ_w , the wobble angle. The microquake theories suggest that θ_w is limited by starquakes to values of the order of 0.1 radians (refs 5, 7, 8); however, the lack of observed wobble⁴ (and in particular, the constancy and sharpness of the optical Crab light curve) suggests that 0.1 be taken as an extreme upper bound, and that θ_w probably lies between 10^{-3} and 10^{-2} radians. The wobble question is the most uncertain part of this analysis (see ref. 6 for comments and references).

The most probable values for the vital parameters in determining the gravitational luminosity are summarised in Table 1, for the standard Crab model, the PPS¹⁰ (stiff equation of state) 1.33 M_\odot Crab, and for Vela. The resulting gravitational wave luminosity L_{GW} , the energy flux at Earth $\mathcal{F} \equiv L_{GW}/4\pi R^2$, and the wave amplitude (strain, or metric perturbation)¹⁴ $h \equiv (16\pi G\mathcal{F}/c^3\omega^2\tau)^{1/2}$, are given together with their probable ranges using the parameter estimates described above. The errors have been added coherently, not by quadrature, so the range covered is rather large; most of the uncertainty comes from the uncertainty in θ_w .

It is possible, of course, that something is radically wrong with the above assumptions. On the other hand, if internal toroidal magnetic fields exist with $B \gtrsim 10^{15}$ G (refs 3, 6), they could produce an oblateness $\varepsilon_0 \sim 10^{-35} (B/1 \text{ G})^2$ comparable with or larger than the fluid oblateness. If the protons in the neutron star form a type-2 superconductor^{15,16} with critical field $H_{c1} = (4 \text{ to } 8) \times 10^{14}$ G, then in the low-flux-density limit ($B \ll H_{c1}$) $\varepsilon_0 \sim 10^{-35} B H_{c1}$ and so smaller internal fields may begin to cause a significant oblateness. In both cases, the internal fields may tend to align themselves perpendicular to the spin axis of the star¹⁶ (effectively $\theta_w = 90^\circ$) and would thus be maximally efficient in producing gravitational radiation. An internal field of 10^{15} G would make a wave of amplitude $h \sim 5 \times 10^{-27}$ from the Crab's distance; a field of 10^{12} G in a type-2 superconductor would produce $h \sim 2 \times 10^{-30}$. So it is improbable that h is much less than the minimum estimates (2×10^{-29} for the Crab, and 1×10^{-27} for Vela) which starquake theory suggests.

The wave amplitude h could, however, be larger. Mountains or other local inhomogeneities in the crust or core could conceivably produce a net nonaxisymmetric oblateness of the same order of magnitude as the materials' shearing strengths^{2,10}, several orders of magnitude larger than the starquake models predict. An extreme upper limit on L_{GW} can be set by requiring that gravitational radiation account for the entire observed slowdown of the pulsars. That limit yields⁴ for the Crab, $L_{GW} \lesssim 2 \times 10^{38} \text{ erg s}^{-1}$, $\mathcal{F} \lesssim 7 \times 10^{-7} \text{ erg cm}^{-2} \text{ s}^{-1}$, $h \lesssim 8 \times 10^{-25}$ and for Vela, $L_{GW} \lesssim 2 \times 10^{37} \text{ erg s}^{-1}$, $\mathcal{F} \lesssim 1 \times 10^{-6} \text{ erg cm}^{-2} \text{ s}^{-1}$, $h \lesssim 3 \times 10^{-24}$, which coincidentally agrees with the upper-bound estimate for Vela on the basis of maximum credible oblateness (Table 1).

To detect the quadrupole radiation at frequencies ω_{GW} of 380 s^{-1} for the Crab and 140 s^{-1} for Vela, some workers envision using large monocrystals, probably of sapphire or silicon (Bagdasarov *et al.*, and Douglass, unpublished data). For crystals of effective length l and effective mass m , the change in amplitude of oscillation due to absorption of gravitational waves in phase with the crystal's oscillation during a measurement time τ is (assuming $\tau \ll \tau^*$, the damping time):

$$\Delta X_{GW} = \tau \omega h / 2$$

Brownian motion at temperature T in a crystal with damping time τ^* ($\tau^* \equiv 2Q/\omega$) produces an amplitude change

$$\langle \Delta X_{Brwn}^2 \rangle^{1/2} = (2\tau k T / m \omega^2 \tau^*)^{1/2}$$

where k is Boltzmann's constant.

For a reasonable signal-to-noise ratio¹⁷ of 10, the minimum detectable wave has amplitude

$$h \gtrsim 10 \left[\frac{2kT}{mQ\omega^3 l^2 \tau} \right]^{1/2} \approx 7 \times 10^{-28} \left(\frac{T}{10^{-3} \text{ K}} \right)^{1/2} \cdot \left(\frac{10^5 \text{ g}}{m} \right)^{1/2} \cdot \left(\frac{10^{14}}{Q} \right)^{1/2} \cdot \left(\frac{380 \text{ s}^{-1}}{\omega_{GW}} \right)^{3/2} \cdot \left(\frac{10^2 \text{ cm}}{l} \right) \cdot \left(\frac{10^7 \text{ s}}{\tau} \right)^{1/2}$$

It is straightforward to verify that detection of this signal would not require a 'quantum non-demolition sensor'^{17,18}, though the construction of the required sensor would be a nontrivial task. The minimum detectable wave amplitude for Vela is a factor of 4 higher, due to its lower frequency. The values of T , m , Q , l , and τ assumed above are not unreasonable goals for the next 5–10 yr of experimental effort¹⁹. It thus seems that, if the Crab or Vela pulsars are as strong as the best estimates indicate, they may be borderline-detectable by gravitational astronomers within the 1980s.

I thank Carlton M. Caves, Peter Goldreich, Kip S. Thorne and David Douglass for helpful comments on this subject.

Distance limit for a class of model γ -ray burst sources

THE observed time structures of γ -ray bursts of the type reported by Klebesadel *et al.*¹ place an upper limit $l \approx 10^9 \text{ cm}$ on the typical size of the burst source regions². If the sources were too far away and isotropically radiating then the observations would require such a high density of photons that the sources would be optically thick in the MeV region simply due to γ - γ -pair production. These considerations do not apply directly to highly beamed sources or relativistically expanding sources. I point out here that MeV photons have actually been observed in bursts, and that this means that non-relativistic sources cannot be further away than a few kpc from the Sun and therefore must be galactic.

Some of the available spectral burst data^{3–8} show a significant flux of photons in the $> 1 \text{ MeV}$ range^{3–5,8}. The 27 April 1972, event observed by Apollo 16 (ref. 3) shows at higher energies a power law spectrum with a possible line feature around 4 MeV. However, power law spectra and lines cannot escape with significant intensity from homogeneous optically thick sources, and if the lines were generated in different spatial regions that are optically thin it would seem to be difficult to get the energy into

these regions to excite MeV lines and nothing else. Another possibility would be to generate the burst in a thin shell surrounding the volume of radius l . But that does not significantly decrease the self-absorption of the source, as shown below.

In case of rapidly varying thermal radiation from an optically thick source it is not easy to construct a spectrum that is a power law at high energies when integrated over the burst duration. A cooling blackbody can account for some lower energy features of the burst spectrum⁹, but not for the high energy tail.

For most events there is insufficient information available on the time structure of the burst around 1 MeV. However, the 18 December 1972 event—although it was not observed at 1 MeV—showed no rapid spectral changes on the time scale of the fast sub-bursts⁷, and a generally increasing hardness near the beginning of the burst. These data suggest that the high energy fast time structure may not be significantly different from the lower energy time structure.

The significance of photon-photon pair production in astrophysical situations has been investigated for a variety of cases. Nikishov¹⁰, and Fazio and Stecker¹¹ considered the absorption of very high energy photons by thermal photons in intergalactic space. Jelley¹² investigated that same mechanism for quasars and other radio sources. McBreen¹³, and Stecker and Tsuruta¹⁴ applied these considerations to the Crab pulsar NPO532, and Rengarajan¹⁵ considered the escape of γ rays from hot neutron star surfaces. In a more general assessment Herterich¹⁶ showed that intense X-ray sources are optically thick for γ rays above a few MeV and therefore cannot be high energy γ -ray sources.

To estimate the optical depth of a homogeneous, isotropic radiation field we have used the formulae as used earlier by Nikishov¹⁰, Jauch and Rohrlich¹⁸, and Gould and Schröder¹⁷. For simplicity we assume that all photon-photon encounters take place at $\theta = 90^\circ$ between the momentum vectors of two interacting photons. The threshold energy ε_{th} of an ambient photon for photon-photon pair production, interacting with a test photon of energy E , is

$$\varepsilon_{th} = (2m^2c^4)/E(1 - \cos\theta) \quad (1)$$

Here mc^2 is the electron rest energy. The cross section $\sigma_{\gamma\gamma}$ has a maximum of $1.7 \times 10^{-25} \text{ cm}^2$ at $\varepsilon_0 = 2\varepsilon_{th}$.

For a typical source radius l and ambient photon density $n \text{ cm}^{-3}$, the optical depth for the test photon is typically

$$\tau(E) = l \int_{\varepsilon_{th}}^{\infty} n(\varepsilon) \sigma_{\gamma\gamma}(E, \varepsilon) d\varepsilon \quad (2)$$

With the observed photon number flux $F(\varepsilon) \text{ cm}^{-2} \text{ s}^{-1} \text{ keV}^{-1}$ the spatial density of photons on the surface of the source is $n = (F/c)(D^2/l^2)$ where D is the distance of the source; hence

$$D(E) = \left(\frac{\tau l c}{\int_{\varepsilon_{th}}^{\infty} F(\varepsilon) \sigma(E, \varepsilon) d\varepsilon} \right)^{1/2} \quad (3)$$

For integration we make two alternate assumptions for the spectral shape of the flux $F(\varepsilon) \text{ cm}^{-2} \text{ s}^{-1} \text{ keV}^{-1}$. We consider (a) a composite spectrum⁴

$$\begin{aligned} & \frac{F^{(a)} \text{ cm}^{-2} \text{ s}^{-1} \text{ keV}^{-1}}{(\text{erg cm}^{-2} \text{ s}^{-1})} \\ &= 1.6 \times 10^4 \exp(-\varepsilon/150 \text{ keV}) \quad (\varepsilon \leq 375 \text{ keV}) \\ &= 3.9 \times 10^9 (\varepsilon/\text{keV})^{-2.5} \quad (\varepsilon > 375 \text{ keV}) \end{aligned}$$

and (b) for comparison we consider a pure power law

$$\frac{F^{(b)} \text{ cm}^{-2} \text{ s}^{-1} \text{ keV}^{-1}}{(\text{erg cm}^{-2} \text{ s}^{-1})} = 1.9 \times 10^8 (\varepsilon/\text{keV})^{-2}$$

This is the photon number flux normalised to a burst of integrated energy flux of $1 \text{ erg cm}^{-2} \text{ s}^{-1}$. For normalisation of case (b) we

Fig. 1 Distance where source of $3 \times 10^{-5} \text{ erg cm}^{-2} \text{ s}^{-1}$ burst is optically thick, $\tau = 1$. Homogeneous isotropically radiating burst sources are optically thick at the abscissa energy if assumed to be further away from the Sun than indicated on the ordinate. The two photon number spectra of bursts (upper curve for the composite spectrum) have been assumed without cutoffs.

have assumed that 70% of the usually quoted energy of the burst is found between 100 keV and 1,000 keV.

As an example we take a typical burst of size $10^{-4} \text{ erg cm}^{-2} \text{ s}^{-1}$. The actual energy flux of such a burst is around $3 \times 10^{-5} \text{ erg cm}^{-2} \text{ s}^{-1}$ with wide variations. We assume now that the optical depth of the source region should be $\tau < 1$ in order to assure the escape of the test photon. With this we arrive at Fig. 1. Since a fair number of events have been detected near 1 MeV (refs 3–5, 8), and all show deviations from an exponential spectrum, we take the $\tau = 1$ distance derived for 1 MeV for the upper limit of the distance to a $10^{-4} \text{ erg cm}^{-2}$ homogeneous isotropic burst source, which is $D \approx 2 \text{ kpc}$ according to Fig. 1. Thus this type of burst source must be galactic. The photon number flux fluctuates greatly during the burst, and the actual momentary fluxes are often significantly greater than the average fluxes. So our upper limit should be rather generous.

This distance limit was estimated for $l = 10^9 \text{ cm}$ sources which are isotropically radiating with initial photon density constant throughout the source volume and the same as on its surface. If the radiation were to emerge only from a surface around the source, but each surface element were radiating isotropically, then near the source the photon density would still be quite high, but the average angle of encounter would be less than 90° . A similar situation was considered previously¹⁹, and for our case we find that the $\tau = 1$ distance would be insignificantly larger than our upper limit. Also, if the high energy radiation of the event of 27 April 1972 were a 4.4-MeV carbon line feature with a typical time scale of about 5 s and intensity $10^{-1} \text{ s}^{-1} \text{ cm}^{-2}$, then the typical source radius would be about 10^{11} cm , and the resulting $\tau = 1$ distance would be about $3 \times 10^5 \text{ pc}$. Thus even this very extreme assumption would keep the source well within the local group of galaxies.

Within 2 kpc of the Sun there is about 1% of the galactic mass; this holds for either all matter²⁰ or the extreme population I as represented by the hydrogen disk²¹. If the bursts come from objects distributed throughout our Galaxy similar to either one of the two classes of objects then bursts of size $10^{-4} \text{ erg cm}^{-2}$ come from only about 1/100 of the Galaxy. Assuming the widely used standard candle hypothesis where the burst size is inversely proportional to the square of the source distance, the frequency of bursts of size $\geq S$ is at the same time a lower limit to the frequency of occurrences of bursts at distance $\leq D(S)$. Since the frequency of detections of $10^{-4} \text{ erg cm}^{-2}$ bursts is about three per year (refs

22, 23) the upper limit to the distance leads to an upper limit of the average intrinsic luminosity of $\approx 5 \times 10^{40}$ erg and to a lower limit of about 300 burst occurrences per year throughout our Galaxy.

This means that unless very special radiation mechanisms are at work occurrences that are unique in the history of an individual star cannot account for the majority of the bursts that are being detected. The rate of star formation in our Galaxy is at present about two to three solar masses per year²⁴ and supposedly has been constant for the last few times 10^9 yr. We assume for the sake of this argument that this means two to three stars per year. It is difficult to see how the rate of irreversible star transformations could be two orders of magnitude higher than this rate at the present epoch. Nova explosions also have been suggested as γ -ray burst sources. The rate of optical novae per year has been estimated to be about 30 to 50 in our Galaxy^{25,26}, and 25 to 30 in M31 (refs 27, 28). These numbers would be, considering the usual uncertainty of numbers in astrophysics, marginally compatible with our number of burst occurrences. However, considering the high degree of isotropy of the detected burst directions^{22,29} we feel we can also exclude novae as the major contributors to γ -ray bursts. Therefore, we suggest tentatively that the γ -ray bursts that have been detected are galactic, but are in the majority of the cases not connected with unique irreversible star transformations, and also it is unlikely that they are connected with galactic novae.

In the case of beamed sources the threshold energy (1) depends on the opening half angle $\Gamma/2$ of the beam. Using the same arguments as Stecker and Tsuruta¹⁴ we assume $\theta \approx 2^{1/2} \Gamma/2$. Assuming that 5 MeV photons have been observed^{3,5} we set $\epsilon_{th} \approx 2.5$ MeV and from this with (1) we derive $\Gamma/2 \approx 12^\circ$. With (3) we find that such a source should be optically thick ($\tau = 1$) at 5 MeV if placed further than 6 kpc from the Sun. The galactic fraction of matter within this distance is about 1/10 of the total, and the solid angle covered by the $\Gamma/2 = 12^\circ$ burst is $1/8$ sr, so that in the same way as above we arrive at a minimum number of burst occurrences throughout the galaxy of $8 \times 4\pi \times 10^3 \approx 3,000$ yr⁻¹. Hypothetical beams narrower than 12° cannot be assessed in this way, because the energy where absorption can become important ($\leq 2 \epsilon_{th}$) is not covered by observations, yet. Thus for not too narrow beams the conclusions are essentially the same as above.

I emphasise here that the conclusions reached depend entirely on observed parameters. No specific assumption had to be made about particles or fields within the sources. Generally, particles or fields can also serve as absorbing agents so that their presence can only increase the optical depth of the source and therefore put even more severe constraints on the distance of the sources.

I thank F. W. Stecker, R. Ramaty and T. L. Cline for helpful discussions. I am an NAS/NRC Resident Research Associate.

Runaway stars as witnesses to supernova explosions

THE hypothesis that single runaway stars are released from close binaries in which the companion star explodes as a carbon detonation supernova and is totally disrupted¹ is proposed here. This is contrary to the earlier belief² that at the time of the explosion the more evolved star is the less massive so that the supernova explosion which leaves behind a relativistic star core does not disrupt the binary³ but accelerates it to a velocity of a few tens of km s⁻¹ (ref. 4). The binary consisting of a normal OB star and an inactive compact star could be detected as a runaway till it shows itself as an X-ray source.

From the stars that can explode as supernova, it is only the lower mass stars that burn carbon explosively⁵. Therefore if the above hypothesis is correct, lower mass runaways should be predominantly single, while the higher mass runaways should be predominantly binaries containing inactive compact stars. This is shown to be the case in Fig. 1 (based on data from ref. 6). Of the 55 runaways (peculiar velocities ≥ 40 km s⁻¹) listed, 29 have masses $< 15 M_\odot$ out of which only 7 (24%) are deduced to be binaries on the basis of radial velocity variations. On the other hand, out of 26 runaways with masses $\geq 15 M_\odot$, 14 (54%) are deduced to be binaries.

For a supernova explosion to take place in a close binary, the primary (the 'first' star) should start with a mass $\geq 15 M_\odot$. If the

Fig. 1 Mass distribution of runaways. The shaded area refers to the distribution of runaway binaries containing inactive compact stars. Runaways with masses $\geq 40 M_\odot$ are clubbed together.

second star is to collect the matter being transferred from the first star it should have a main sequence mass of about $4 M_{\odot}$ (ref. 3), because if the mass ratio is smaller than 0.3, mass transfer to the second star would make it thermally unstable, leading to the formation of a contact binary and large mass loss from the system⁷. If all the mass lost by the first star is collected by the second star, there must be a lower limit on the mass of a single runaway star. Assuming that the main sequence masses of the components were $15 M_{\odot}$ and $4 M_{\odot}$ and that the mass transfer left the first star as a helium star of mass $5 M_{\odot}$ whose supernova explosion disrupted the binary, the minimum mass a runaway could have is $14 M_{\odot}$. The fact that there are runaways with masses as small as $7 M_{\odot}$ (ref. 6) proves that during mass transfer phase, about 50% of the mass being transferred is lost from the system. A similar mass loss has been invoked⁸ to obtain a better quantitative agreement between theory and observations for Algol-type systems.

Azimuthal brightness variation of Saturn's ring-A and size of particles

OBSERVATIONS of the brightness of ring A of Saturn, indicate that it is not constant in azimuth. This was discovered by Camichel¹, and later studied by me². Reitsema *et al.*³ and Lumme and Irvine⁴, have confirmed these observations. The A ring is fainter in quadrants following conjunction of the particles with the Earth-Saturn line, and brighter in quadrants preceding conjunction. No azimuthal brightness variation of this type is found for the B-ring⁵. Because these observations do not show any time dependence, the effect is stationary. We will call this, fact A. A possible explanation for it has been given by Colombo *et al.*⁶. Here we give an alternative explanation for fact A, which would be valid if the particles in ring A are large, which we will show is indeed the case, using a recent measurement¹¹ of the total mass of the rings.

This observational fact implies four conditions: (1) the light showing the variation has to come from the surface of the particles (the amplitude of this variation is around 30%); (2) the particles are in synchronous rotation; (3) rotations around the planet-particle axis are not allowed; (4) the albedo of the particles changes around them, or they are elongated and tilted with respect to the orbital radius. Note that all these conditions must be satisfied. If any were not, fact A would not apply. Condition (1) rules out the bright-cloud model of Pollack⁶ for ring A. That the particles are in synchronous rotation is not a surprise, as most of the satellites of Saturn are in such a state⁷. Condition (3) implies that collisions are not capable of turning the particles around, or that they are not important today. Finally, condition (4) presents two alternatives: an albedo change over the particles, or particles with their major axis not pointed exactly to Saturn, but inclined to it. A possible explanation of fact A based on this last possibility, has been given by Colombo *et al.*⁸, using a mechanism of travelling waves related to the one that produces the spiral arms in galaxies. Another possibility based on the first alternative (an albedo variation over the particles) implies that collisions have been important in Saturn's rings in the past, and it seems to us a much simpler explanation for fact A.

To understand this mechanism, we will use Fig. 1 which shows two particles of the rings seen from above, which are about to

Fig. 1 Two particles about to collide in the rings. As particle 1 is nearer to the planet, it moves faster. Then collisions can occur only in the third quadrant (180° to 270°) of the first particle, or in the first quadrant (0° to 90°) of the second. There is no way in which the second and fourth quadrants of the two particles can be reached, if the particles preserve their relative radial positions. Note that the collisional regions are bright. This configuration is consistent with the azimuthal brightness variation observed in ring A.

collide. Particle 1 moves faster than particle 2, since $r_1 < r_2$, and so 1 overtakes 2. It is clear then that if we use the system of coordinates drawn on particle 2, collisions can occur only in the third quadrant ($180^\circ < \phi < 270^\circ$) of the first particle, and on the first quadrant ($0^\circ < \phi < 90^\circ$) of the second particle. There is no way in which the other quadrants can be reached. Thus we would expect some qualitative changes on the surface properties of the particles due to the effects of collisions in these two quadrants. Observationally, fact A shows that the collisions produce bright regions.

The above explanation is valid only if each particle preserves its radial positions with respect to others. Franklin and Colombo⁹ have shown that a particle at the centre of ring A is displaced by $\sim \Delta R = \pm 147$ m in the radial direction due to perturbations by the satellites. The rate of precession of the orbits of the different particles in the rings due to the Sun and other Saturnian satellites, is a function of the radial distance to the planet. Contiguous orbits will have different rates. Secularly the radial displacements for two nearby particles will not be in phase, but their values will still be given by ΔR . So for a particle to preserve its position with respect to others, its size has to be of the same order of magnitude or larger than ΔR . If this were not the case, collisions would be allowed in all quadrants and no azimuthal variation would be produced. Thus the diameter of the particles is $D > 2\Delta R \approx 290$ m. This value again rules out the bright-cloud model of Pollack⁶ for ring A, since it requires $D \approx 10$ cm.

Additional evidence for large particles can be derived from a paper by McLaughlin and Talbot¹¹. They have obtained the total mass of the rings, from the observed secular apsidal and nodal rates of the inner satellites. They found $M_{\text{rings}} = (6.2 \pm 2.4) \times 10^{-6} M_{\text{Saturn}}$, for a rotational period of Saturn of 10 h 26 min. If a period of 10 h 14 min is adopted², their value is changed only slightly to $(5.9 \pm 2.4) \times 10^{-6} M_{\text{Saturn}}$. I have pointed out previously¹⁰ that the mass of the rings and the mean particle size are linearly related, and knowing one of them

permits the evaluation of the other. I also presented a functional relationship, for mean densities of 1.0, 2.0 and 5.0 g cm⁻³. Using the later value of the mass, we obtain mean radii of the particles of $\bar{r} = 1.9, 1.0$ and 0.5 Km, for the different densities, respectively. It is hard to escape from this conclusion, because this result is based on well known determinations of the optical thickness of the rings^{5,10}, and is insensitive to the ring model adopted.

A possible stable configuration in which the particles would preserve their radial positions could be if the particles move in an orderly fashion in smaller rings, of separation $s \gtrsim D \gtrsim 2\Delta R$ (see Fig. 2). There is some evidence that this BIAS model (beads in a string) could be correct.

Jeffreys¹² had shown that a multilayer of particles rotating around a massive primary, would transfer angular momentum inward and outward, until the ring becomes one particle thick, and the particles are separated radially by a distance equal to their diameters. The transfer of angular momentum then ceases. He derived an approximated formula for the time to reach this state: $t \simeq 10^6 \text{ yr}/D \text{ (cm)}$. This time is very short even for small particles. Presumably Saturn's rings should be in this state, and thus collision should be rare between radially neighbouring particles, in agreement with condition (3).

Fig. 2 BIAS configuration proposed for ring A. In this model particles move orderly in concentric sub-rings. The particles are slightly elongated, and point toward Saturn maintaining synchronous rotation. There is a fine envelope of smaller particles surrounding the rings. These would help to damp oscillations and add to the stability of the configuration. Only the large particles show an azimuthal effect.

Once the particles are in a monolayer, current theories of jet-streams^{13,17} indicate that narrow rings could be generated. In trying to prove this result, Baxter and Thompson¹⁴ have taken a population of disks in a plane, moving in keplerian orbits around a primary. Disks were taken due to mathematical simplicity. The Boltzmann-like kinetic equation for the development of the particle distribution function could be expanded as a Fokker-Planck equation for the diffusion of that function. If the elasticity of the collision were small, the diffusion coefficient would be negative, indicating that regions of enhanced density would be formed. However, a rather low value of the elasticity was found necessary for this to happen. Due to the neglect of several important physical processes, their value must be considered as a lower limit. A realistic model should include besides collisions, sliding friction between the surfaces, work done to

displace the particle from its Saturn orientation, and a possible cloud of gas and dust around the particles, that could damp all oscillations. For example, the recently discovered linear markings on the martian satellite Phobos¹⁵, could be interpreted as evidence of a sliding collision with another celestial body. From the depth of these markings it is clear that sliding friction could have been rather substantial. Incidentally, the apparition of narrow rings of enhanced density was also found for the case of accretion disks surrounding black holes¹⁶.

Alfvén¹⁷ has considered the case of several apples inside a spacecraft, rotating around a planet. He found that the apples would be found neatly located at the centre of the spacecraft, in a line parallel to the orbit. In this case the focusing is produced by the walls of the spacecraft. Particles in Saturn's rings are not inside a spacecraft, but the surrounding particles could conceivably produce the same effect.

Perhaps the best evidence in favour of a BIAS model is not theoretical but observational. Such evidence lies with the discovery of narrow rings around Uranus^{18,19}, situated $\sim 40,000$ km from the planet. At the distance of Uranus, the size of the occulted star was around 4 km, so a large resolution was not possible. But from the duration of some of the events (~ 0.7 s) the conclusion is that these rings are very narrow, and cannot be wider than a few kilometres^{18,19}. The particles composing this ring have then to be smaller than a few kilometres. Note the coincidence of this value with that for the particles in Saturn's rings. This is the best evidence that narrow rings are formed in the Solar System, and could have been formed in Saturn's rings as suggested by fact A.

In conclusion, large particles for the rings have several advantages: first, they explain fact A if particles are in a BIAS configuration; second, they explain the shift in position of the outer boundary of ring B, found by Franklin *et al.*⁹; third, it is the only way of obtaining a large mass for the rings¹⁰, as found by McLaughlin and Talbot¹¹.

Observations of strong wind shear using pulse compression radar

THE occurrence of layers of strong wind shear is interesting because of their relationship to turbulence and because of their effect on aircraft, rockets and missiles crossing them. The most extensive source of data on wind shear is from ascending balloon-borne targets but these provide individual profiles of uncertain representativeness and often lack vertical resolution. Measurements from aircraft provide more detailed data. Other sources of high resolution data being used increasingly are

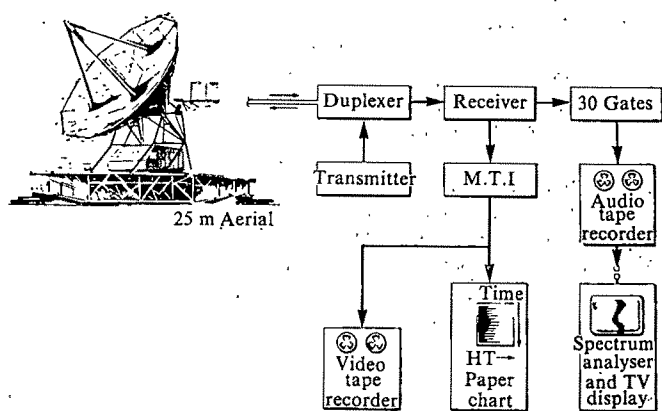

Fig. 1 Forms of data output from the Defford radar.

remote probing techniques capable of measuring the Doppler shift from windborne natural targets, such as, cloud or dust particles and inhomogeneities of temperature and humidity. Although most of these techniques have been developed for use at short range in the atmospheric boundary layer, microwave pulsed Doppler radar is one technique by which a ground-based installation can sometimes obtain wind measurements to quite high altitudes¹. Normally the spatial resolution of such radars is on the order of hundreds of metres. Here we report some observations of very strong shear made using a pulsed Doppler radar specially designed to achieve high spatial resolution.

The 25 m diameter aerial at Defford² has been coupled to a 10.7 cm wavelength radar (an FPS-18 on loan from the National Center for Atmospheric Research) redesigned to give a fine range resolution together with full Doppler measuring facilities. At present the peak power is limited to 320 kW. It has been modified to transmit frequency-modulated pulses of length 600 m. After reflection from targets these pulses are received, compressed and range-gated to give a resolution in range of 30 m. This is comparable with the beam-width resolution at a range of about 5 km.

The high gain of the aerial (53.2 dB), the low receiver noise temperature (170 K) and compression ratio (15 dB) produce a high sensitivity. The minimum detectable reflectivity for an extended target is $1.2 \times 10^{-15} \text{ m}^2 \text{ per m}^3$ at a range of 5 km. Two phase sensitive detector outputs from the receiver give the in phase and quadrature components of the Doppler frequency. They enable velocities to be measured unambiguously over the range $\pm 25 \text{ ms}^{-1}$. As large returns from the ground, received in the aerial side-lobes, tend to mask the wanted targets, a range gated MTI (moving target indicator) has been built to filter out the stationary targets. This device has 256 gates, each 30 m wide, covering a total range of 7.5 km which can be set anywhere between 0 and 100 km.

The methods of recording the data are shown in Fig. 1. The output of the MTI is displayed on a rapidly processed photo-

Fig. 2 Vertical profiles of wind shear and Richardson number derived over layers 430 m deep from the radiosonde released at 1450 GMT.

graphic strip chart to provide an intensity modulated time-range record of target reflectivity in real time. Doppler information from 30 selected range gates covering a total range of 900 m are also recorded on audio tape. This can be replayed rapidly and frequency spectrum analysed to give an RV (range-velocity) display on a colour television. Different colours represent different levels of echo intensity in each element of the RV matrix. If other batches of 30 range gates need to be processed similarly they are extracted from a video recording of the raw radar data.

Radar observations described here were obtained between 1446 and 1454 GMT on 30 March 1977. A balloon-borne radiosonde released during this period from the radar site showed a strongly sheared layer of strong static stability in the middle troposphere between 6.0 and 7.7 km. The Richardson number over much of this layer, evaluated over 430 m height intervals (Fig. 2), was close to 0.25. This is regarded as the critical value for the onset of Kelvin Helmholtz (KH) shearing instability³.

The radar beam was fixed throughout the period of the observations, looking at an elevation angle of 60° into the direction (330°) of both the wind and the wind shear vector over the strongly sheared layer. The 60° elevation angle was a compromise which enabled the radar to detect a major component of the horizontal wind at the same time as obtaining a nearly vertical profile of this component. Figure 3a is a print of the rapid processor time-range display. The ordinate is labelled in terms of true height allowing for the 60° elevation of the radar beam. Figure 3a shows the pattern of echo received mainly from small ice particles at the top of a cirrus cloud deck. Before 1440 the cloud top consisted of gently and uniformly inclined streamers of ice particles falling at less than 1 ms^{-1} . Figure 3a shows that, for a time after 1440, these streamers were distorted in a wave-like manner in the strongly sheared layer between 6.0 and 7.7 km. The crests of the waves were displaced to the right in the upper half of the layer and the troughs were displaced to the left in the lower half of the layer so as to be situated almost directly beneath the crests in the upper part of the layer. This is consistent with the pattern of air motion associated with large-amplitude KH billows⁴. This paper illustrates the capability of the radar to reveal the regions of strong wind shear which were associated with these billows.

Two examples of the format of the basic high-resolution range-velocity data are shown in Fig. 4. Velocity-height matrices such as these were obtained at 3 s intervals. Each element in the matrix is 26 m in height (30 m in slant range) by 0.625 ms^{-1} in radial velocity. As the likely fall speed of the ice particle tracers and the maximum vertical air velocity inferred from the slope of the streamlines of Fig. 3a was small ($< 1 \text{ ms}^{-1}$) compared with the horizontal wind ($> 20 \text{ ms}^{-1}$), the horizontal wind velocity can, to a first approximation, be taken as twice the indicated radial Doppler velocity component. Using such data, we have derived a time-height diagram of the inferred horizontal wind speed for the top half of the disturbance (Fig. 3b). We have also derived the pattern of vertical wind shear over 52 m height intervals (Fig. 3c). Although neglect of vertical air motions does create errors in wind shear of up to $\pm 30\%$ in places, a corrected pattern of wind shear which has been derived, whilst different from Fig. 3c in detail, does not dramatically alter the overall pattern of shear.

At 1436 GMT, before the billows developed, the Doppler measurements had shown that the shear over the 400 m height interval between 6.75 and 7.15 km was uniform at $2.5 \times 10^{-2} \text{ s}^{-1}$. At times, however, during the period depicted in Fig. 3 the shear within this height interval increased locally by as much as a factor of 8, when evaluated over 52 m height intervals. The resulting shear, $20 \times 10^{-2} \text{ s}^{-1}$, can be regarded as very strong for the free atmosphere. The small vertical extent and the transient nature of the regions of strong shear would make them difficult to observe by more conventional *in situ* sensing techniques.

A pulsed microwave radar technique for obtaining high resolution measurements of wind shear has been described. The

Fig. 3 Time-height record of (a) intensity of radar echo between 1446 and 1454 GMT on 30 March 1977 showing wave-like perturbations at the top of a layer of cirrus cloud. Assuming that the pattern was advecting at the speed of the wind at the middle of the perturbed layer, the wavelength would have been 3.4 km. Time-height records are also shown of (b), inferred horizontal wind velocity and (c), inferred vertical wind shear computed over layers 52 m deep. The data in (b) and (c) are for the height interval shown between dotted lines in (a): note the change in vertical scale. Isopleths of velocity in (b) are at 2.5 ms^{-1} intervals. In (c) regions of vertical wind shear exceeding $5 \times 10^{-2} \text{ s}^{-1}$ and $10 \times 10^{-2} \text{ s}^{-1}$ are dotted and black, respectively.

technique has been illustrated by means of a case study in which a vertical wind shear as strong as 0.20 s^{-1} was measured at an altitude of 7 km. The case described utilised small ice particles as tracers of the air motion. It would also work using signals back-scattered from refractive index inhomogeneities associated with humidity and/or temperature fluctuations which, with the present radar, are detectable most of the time in the boundary layer and for some of the time in the upper atmosphere, especially where there is strong shear and turbulence. As the radar operates at a wavelength virtually unattenuated by rain and water vapour it has an all-weather capability. High spatial resolution and an all-weather capability can also be achieved using frequency modulated continuous wave (FMCW) Doppler

radar techniques⁵ but so far such techniques have been restricted mainly to measuring winds in the atmospheric boundary layer.

Distribution of helium in metal tritides

THE first generation of fusion reactors will utilise the reaction between deuterium and tritium nuclei. Various metal tritides, therefore, have potential applications for the transport, storage, purification, isotope enrichment and gettering of tritium. Although many properties of the metal tritides can be estimated¹ from the corresponding hydrides and deuterides, the effects of the radioactive triton decay into a β -particle and ^3He atom with a half life of 12.3 yr can only be determined by direct observation. Considering the expected² insolubility of inert ^3He atoms in metal lattices, it is surprising that many

metal tritides^{1,3,4} contain ³He/T atom ratios in excess of 0.10. The physical state of the retained ³He in these tritides is a very interesting and unresolved problem. Weaver and Camp^{5,6} suggest the ³He atoms are trapped in the octahedral interstitial sites for tritides with fluorite crystal structures while Bowman, *et al.*¹ believe the ³He atoms primarily reside in microscopic gas bubbles with dimensions < 1,000 Å. Here we describe nuclear magnetic resonance (NMR) studies of the relaxation times for ³He nuclei in LiT, TiT_{1.9}, and UT₃, which are representative of ionic, transition metal, and actinide tritides. These NMR measurements support the ³He bubble concept and further indicate an increase in the mean bubble dimensions as the samples age.

The NMR relaxation times are directly related⁷ to the physical state of the resonant spins. When the nuclei are immobile on lattice sites in a solid, the relaxation times obey the relations

$$T_2^* \approx T_2 \ll T_1 \quad (1)$$

where T_2^* is the linewidth relaxation time which corresponds to the experimental linewidth, T_2 is the homogeneous spin-spin relaxation time, and T_1 is the spin-lattice relaxation time. $T_2 < 50 \mu\text{s}$ are typically observed⁷ for rigid atoms in a solid. The molecular motion in macroscopic quantities of bulk gas yields

$$T_2^* < T_2 \approx T_1 \quad (2)$$

The differences in the relaxation times for rigid and mobile spins are dramatic with T_2^* and T_2 increasing by 2–4 orders of magnitude. The measured ³He relaxation times in LiT, TiT_{1.9}, and UT₃ are summarised in Table 1. Standard pulse NMR techniques⁸ were used to determine these relaxation times. The tritides were prepared by reactions at elevated temperatures between pure metals and tritium gas. Samples were sealed in evacuated glass tubes before commencing the NMR studies. The nonexponential decays generally observed during the NMR measurements are indicative^{9,10} of a variety of localised and isolated environments for the ³He spins (that is clusters or microbubbles).

Although the absolute magnitudes of the ³He relaxation times are different for LiT, TiT_{1.9}, and UT₃, these tritides have a common obedience to

$$T_2^* < T_2 < T_1 \quad (3)$$

rather than equation (1) or (2). Furthermore, T_2 and T_1 for ³He in each tritide become significantly longer with age (as the retained ³He contents increase). This behaviour implies a remarkable similarity in the ³He distributions for materials with very different¹ physical characteristics. The observed T_2^*

reflect the relative inhomogeneous line broadening contributions arising from the bulk magnetic susceptibilities¹¹, which accounts¹⁰ for the very short T_2^* in the strongly paramagnetic UT₃.

Nuclear relaxation times for ³He atoms in gas bubbles can be represented by the phenomenological expressions

$$T_1^{-1} = T_{1B}^{-1} + T_{1W}^{-1} \quad (4)$$

$$T_2^{-1} = T_{2B}^{-1} + (\lambda/R)T_{2W}^{-1} \quad (5)$$

where T_{1B} and T_{2B} correspond to bulk gas, T_{1W} is the spin-lattice relaxation at the bubble wall, R is the average bubble radius, and T_{2W} is the spin-spin relaxation time in a surface film of depth λ (approximately 2–3 atom layers). As spin relaxation in bulk monoatomic ³He gas is very inefficient⁷, $T_{2B} \approx T_{1B} > 10^3\text{s}$, and equations (4) and (5) are dominated by the wall relaxation processes. Although the surface relaxation mechanisms are not fully understood, any surface paramagnetic species will rapidly relax ³He spins during collisions with the bubble wall. Assuming relaxation occurs only in the short ($\sim 10^{-13}\text{s}$) collision sticking time t_s , T_{1W} is predicted¹⁰ to be

$$T_{1W} = (4R/3 < v > t_s) T_{1S} \quad (6)$$

where $< v >$ is the average thermal velocity of ³He atoms and T_{1S} is the surface relaxation time. As T_{1S} should be extremely sensitive to the electronic structure and chemical composition of the host material, very different ³He T_1 values for each tritide are expected and observed in Table 1. Furthermore, equation (6) predicts T_1 becomes longer as the bubble radius R is increased. T_{2W} can also be described by a relation similar to equation (6) where $T_{2S} < T_{1S}$ because the semi-static dipolar interactions which dominate T_2 relaxation⁷ would be strongest between ³He atoms near the wall. Consequently, ³He spin relaxation in bubbles would obey $T_2 < T_1$, and T_2 , with an approximately R^2 dependence, would increase more rapidly than T_1 as the bubbles enlarge.

The ³He relaxation times in Table I for LiT, TiT_{1.9}, and UT₃ are in good qualitative agreement with growing microscopic bubbles for the helium distributions in these tritides. Unfortunately, several factors prohibit a more definitive analysis. First, a range of bubble sizes (each with its own characteristic T_1 and T_2) as described by Gruber¹² is more likely than uniform bubble dimensions and the NMR studies will correspond to an 'average' bubble dimension. Various magnetic field gradients also contribute¹⁰ to the observed ³He relaxation times and tend to magnify the R -dependence for T_2 . The T_{1S} and T_{2S} values are unknown for these materials and may also have inherent time dependences which could modify the relationships between observed ³He relaxation times and bubble dimensions. Nevertheless, the ³He relaxation times observed in LiT, TiT_{1.9}, and UT₃ have been shown to be more consistent with helium atoms in microscopic bubbles whose average dimensions increase with age than the alternative explanation^{5,6} of rigidly trapped interstitials. The absence of known T_{1S} and T_{2S} values precludes a reliable determination of the bubbles dimensions from the NMR data in Table 1. However, bubble radii in the range of 10–100 Å are reasonable estimates. High resolution electron microscopy studies are required to establish better the bubble size distribution in the metal tritides.

I thank Dr A. Attalla for help with the NMR experiments.

Exsolution in almandine-pyrope-grossular garnet

MINERALS of the garnet group are common in metamorphic rocks and in xenoliths derived from the Earth's mantle. They consist of multicomponent solid solutions with the general formula $X_3^{2+}Y_3^{3+}Si_3O_{12}$, where X represents Fe^{2+} , Mg^{2+} , Mn^{2+} , Ca^{2+} in 8-coordination, and Y represents Al^{3+} , Fe^{3+} , Cr^{3+} in 6-coordination. Solid solution between $Fe_3Al_2Si_3O_{12}$ (almandine), $Mg_3Al_2Si_3O_{12}$ (pyrope) and $Ca_3Al_2Si_3O_{12}$ (grossular) had been generally thought to be complete at temperatures appropriate to metamorphism. This paper reports the observation of exsolution in a natural garnet of this series from a high-grade metamorphic rock. Electron microscopic techniques have been used to demonstrate the phase separation of iron-rich precipitates from a more calcic matrix.

Theoretical considerations of the approximate thermodynamic properties of pyrope-grossular solid solutions by Ganguly and Kennedy¹ suggested the possibility of exsolution below about 700 °C, but attempts to demonstrate this experimentally proved inconclusive. Experimental data on the mixing properties of almandine-grossular solid solutions indicate the probable existence of a miscibility gap in this system at temperatures as high as 900 °C (ref. 2). The two-phase region calculated from these data occurs towards almandine-rich bulk compositions. These mixing data will be published elsewhere³.

In order to verify the experimental results a natural garnet of bulk composition almandine_{0.49} pyrope_{0.21} spessartine_{0.01} grossular_{0.29}, described by Wood⁴ from a metagabbro (specimen 16) in South Harris, was investigated by scanning and transmission electron microscopy. The metagabbro has been metamorphosed in granulite facies conditions, and Wood⁴ has determined the probable equilibrium pressure and temperature at the peak of metamorphism to be 10–13 kbar and 800–860 °C. The bulk composition of the garnet from this rock lies within the experimentally indicated two-phase field. Scanning electron micrographs of this garnet etched with 5% HF solution show preferential etching which produces surfaces composed of roughly spherical-shaped particles of various sizes up to about 0.5 µm diameter. The garnet seems to be composed of a microaggregate of particles.

Transmission electron micrographs of ion-thinned samples show the garnet to be composed of many individual polyhedral particles, set in a matrix which has been more easily etched by the ion-thinning process (Fig. 1). The size of individual polyhedra is variable up to about 0.4 µm, but most are less than 0.1 µm in diameter. The larger polyhedra often appear to be distributed in zones within the garnet (Fig. 1b). Contrast features in the matrix also suggest a finer scale of precipitation. The size and distribution of exsolved polyhedra may reflect the retrograde pressure temperature history of the rock, but further coarsening of exsolution textures at low temperatures may be hindered by small diffusion coefficients for garnet.

Analytical electron microscopy at 100 kV using EMMA-4 (ref. 5) has enabled the chemistry of the polyhedra and of the matrix to be determined. By focusing the beam into a small probe it is possible to analyse individual areas of 0.1–0.2 µm diameter. The matrix and polyhedra both have garnet stoichiometry, but the matrix is richer in calcium than the adjacent polyhedra. Results of chemical analyses calculated as mole fractions of grossular component (Ca/Ca + Mg + Fe) are shown

Fig. 1 Transmission electron micrographs of ion-thinned garnet, showing exsolved iron-rich garnet polyhedra. The polyhedra appear dark, partly due to diffraction contrast and partly due to thickness, as the more calcium-rich garnet matrix is preferentially etched during the ion-thinning process. Smaller precipitates are also visible in the matrix. *a*, Scale bar 0.1 µm; *b*, 0.2 µm.

in Table 1. Defocusing the electron beam to cover an area containing both exsolved polyhedra and matrix gives an analysis representative of the bulk composition, which is in good agreement with conventional microprobe results⁴.

An electron diffraction pattern from an area including many small polyhedra within the matrix is shown in Fig. 2. Dark field microscopy indicates that the regular array is from the matrix and the spotty powder rings from the randomly orientated polyhedra; both index as garnet. Cell-edges calculated from the regular array and from the powder rings differ relatively by 0.12 Å, with the regular array from the garnet of larger cell-edge. This value of 0.12 Å corresponds to a compositional difference in pyrope-almandine-grossular solid solutions of about 0.25 mole fraction of grossular component, in agreement with the chemical difference found using EMMA-4 and with the

Table 1 Garnet analyses

	Polyhedra	EMMA-4 Matrix	Bulk	Microprobe ⁴ Bulk
Ca/Ca + Mg + Fe	0.22	0.37	0.28	0.29
(mol fraction)	0.20	0.32	0.29	
	0.19	0.40	0.29	
	0.21	0.35	0.26	
Average	0.20	0.36	0.28	0.29

EMMA-4 analyses represent a minimum compositional separation, as with a probe size of 0.1–0.2 µm it is often not possible to analyse single polyhedra without including some matrix. Also, the matrix often contains very small precipitates. Therefore, areas suitable for analysis of mainly single phases were carefully chosen.

Fig. 2 An electron diffraction pattern from an area including many small polyhedra within the matrix. The regular array is from the matrix and the spotty powder rings from the randomly orientated polyhedra. Garnet cell-edges differ by 0.12 Å.

experimental mixing data. The diffraction pattern is, therefore, consistent with the interpretation that randomly-orientated garnet polyhedra have exsolved from a more calcium-rich garnet matrix.

Two distinct garnet phases produced by an exsolution mechanism are likely to be observed in almandine-pyrope-grossular garnets from metabasic rocks, as garnets from this paragenesis generally have more calcic bulk compositions (up to 30 mol % grossular) than those from metapelites. Exsolution may also occur in more complex garnet solid solutions which contain the components $\text{Ca}_3\text{Cr}_2\text{Si}_3\text{O}_{12}$ (uvarovite) and $\text{Ca}_3\text{Fe}_2\text{Si}_3\text{O}_{12}$ (andradite) in addition to almandine, pyrope and grossular end-member components.

I thank Drs B. J. Wood, R. Schmid, P. E. Champness and G. W. Lorimer for helpful discussions. The research was carried out during the tenure of a NERC research studentship.

Standards for stable isotope measurements in natural compounds

RESEARCH based on stable isotope variations in natural compounds is expanding in scientific fields such as geochemistry, hydrology, environmental studies and biochemistry. However, intercomparison of results obtained in different laboratories is often not fully reliable and therefore to improve the intercalibration of deuterium and ^{18}O measurements in natural waters, two water standards have been distributed by the International Atomic Energy Agency since 1968. The two standards, called V-SMOW (Vienna Standard Mean Ocean Water) and SLAP (Standard Light Antarctic Precipitation), were prepared, following a recommendation by an Advisory Group Meeting convened by the IAEA in 1966. Information on the two standards is given here.

V-SMOW was obtained by mixing distilled ocean water with small amounts of other waters in order to bring its isotopic composition as close as possible to that of the defined SMOW¹.

According to the control analyses made by Craig, V-SMOW has the same $^{18}\text{O}/^{16}\text{O}$ ratio as the defined SMOW, but a slightly lower D/H ratio (0.2‰). This difference in deuterium content, however, is 5 to 10 times lower than the experimental error of many laboratories.

The D/H absolute ratio² of V-SMOW was $(155.76 \pm 0.05) \times 10^{-6}$. The $^{18}\text{O}/^{16}\text{O}$ absolute ratio³ was $(2005.20 \pm 0.45) \times 10^{-6}$. No determinations were made of the $^{17}\text{O}/^{16}\text{O}$ ratio. The absolute maximum density of V-SMOW is 999.975 kgm⁻³ (see ref. 4). The tritium content of V-SMOW, determined at the IAEA by direct gas counting, was 18.5 ± 3.6 T.U. on 16 September 1976 (1 T.U. (tritium unit) corresponds to 1 atom of tritium per 10^{18} atoms of hydrogen).

SLAP was obtained by melting a sample of firn collected at Plateau Station, Antarctica. Its D/H absolute ratio² was $(89.02 \pm 0.05) \times 10^{-6}$. The tritium content of SLAP was 374 ± 9 T.U. on 16 September 1976.

Two other water standards, the so-called NBS-1 and NBS-1A—formerly kept at the National Bureau of Standards, Washington DC, USA, and now at the IAEA in Vienna—were also distributed together with V-SMOW and SLAP.

In September 1976, a consultants' meeting was convened by IAEA to review the results obtained by different laboratories for the above water standards, to discuss the intercalibration

international organisations. The results submitted up to September 1976 are listed in Tables 1 and 2. The agreement among the different laboratories is reasonably good, and improves significantly by eliminating the results deviating from the average of more than two standard deviations (Table 3).

If fixed δ-values are assigned to SLAP and the δ values of NBS-1 and NBS-1A are normalised accordingly, the agreement of the results should improve. In fact, the measurement technique based on two standards should produce, in principle, results which compare better between different laboratories. In this case, however, the improvement is significant only for the δD value of NBS-1A, as shown by the decrease of the standard deviation.

To resolve confusion due to the expression of results from different laboratories in non-corresponding scales, it is recommended that all future results be expressed as δ-values relative to V-SMOW. Coherence between δ-values reported by different laboratories can be improved by adopting common δ-values for a second water reference standard with respect to which the ¹⁸O and deuterium δ-scales should be normalised. It is recommended, for this purpose, to adopt the water SLAP distributed by the Agency. The recommended δ-values for SLAP relative to V-SMOW are:

δ ¹⁸O (SLAP) = -55.5‰

δD (SLAP) = -428‰

These δ-values for SLAP were selected using data in Tables 1 and 2.

The adoption of V-SMOW as zero of the δ-scales and of prefixed values for SLAP corresponds in principle to a modification of the δ-scale which becomes:

δ = (R_{sample} - R_{V-SMOW}) / R_{V-SMOW} δ_{SLAP} × [(R_{SLAP} - R_{V-SMOW}) / R_{V-SMOW}] (1)

where R = ¹⁸O/¹⁶O or D/H and δ_{SLAP} is the value adopted for ¹⁸O or deuterium content of SLAP with respect to V-SMOW. The classical definition of δ as the relative difference (generally reported in ‰) of the isotopic ratio with respect to SMOW is:

δ = (R_{sample} - R_{SMOW}) / R_{SMOW} (2)

The two δ-scales coincide if R_{SMOW} = R_{V-SMOW} and if the adopted δ-values for SLAP correspond to the true ones as defined by equation (2). These two conditions seem to be fairly well fulfilled and therefore in practice equations (1) and (2) coincide. In addition, errors of δ which can be introduced by an incorrect assessment of multiplicative correction factors automatically cancel from equation (1).

Therefore, the advantages of significantly improving the correct comparison of results obtained in different laboratories by the adoption of recommended δ-values for SLAP far outweigh the consequences of the implications discussed above.

The need for a third reference water sample with isotopic composition approximately midway between V-SMOW and SLAP was also recognised. This sample has been called GISP (Greenland Ice Sheet Precipitation). The IAEA will soon start distributing it, with the aim of calibration on the V-SMOW/SLAP scale.

It was agreed that most of the stock of V-SMOW, SLAP and GISP should be stored in sealed flasks of approximately 10 l each. Some of the flasks should be kept at the US National Bureau of Standards, in Washington, and the rest at the IAEA in Vienna.

About 10 l of each standard should be stored in sealed pyrex vials of about 25 ml for distribution by IAEA. In principle, V-SMOW, SLAP and GISP should be distributed upon request only, but laboratories are encouraged to make a precise calibration of their working standards on the V-SMOW/SLAP scale about once every three years.

The establishment of other stable isotope standards is required in order to improve the intercomparison of results obtained in different laboratories in natural substances other

Table 3 Intercalibration average values and standard deviations

Sample	Deuterium			¹⁸ O		
	δ	σ	n	δ	σ	n

	2. -426.1	4.2	25	-55.45	0.16	35

- 1. All results included as reported in Tables 1 and 2.
- 2. Excluding those deviating by more than 2σ from the average of 1.
- 3. Results normalised with respect to SLAP, assuming for the latter δD = -428 and δ¹⁸O = -55.5. All results included.
- 4. Excluding the results deviating by more than 2σ from the average of 3.

Table 4 Proposed new stable isotope standards

Compound	Elements for which standard can be used	Remarks (and workers willing to investigate the possibility of procuring standards)
CaCO ₃	C, O	Calcite as close as possible to PBD. I. Friedman (Denver, Colorado) and J. O'Neil (Menlo Park, California).
CaCO ₃	C, O	Carbonatite. H. Friedrichsen (Tübingen, FRG).
CO ₂	C, O	Two different gas samples for mass spectrometer calibration. T. B. Coplen (Reston, Virginia).
C ₁₇ H ₁₁ O ₆	H, C, O	Tristearin for studies of organic compounds.
K ₂ Al ₄ (Si ₆ Al ₂ O ₂₀)(OH, F) ₄	H, O	Muscovite. I. Friedman and J. O'Neil.
K ₂ (Mg, Fe) ₆ (Si ₆ Al ₂ O ₂₀)(OH, F) ₄	H, O	Biotite. I. Friedman and J. O'Neil.
BaSO ₄	O, S	Obtained from sea water. Y. Horibe (Tokyo, Japan).
PbS or ZnS	S	Natural galena or sphalerite with $\delta^{34}\text{S}$ in the range -20 to -30‰. I. Friedman and J. O'Neil.
S	S	Sulphur derived from natural gas, depleted in ^{34}S . E. Roth (Saclay, France).
SO ₂	S	Two different gas samples for mass spectrometer calibration. J. O'Neil and I. L. Barnes (Washington D.C.).
(NH ₄) ₂ SO ₄	N	Two samples differing by about 20‰. E. Salati (Piracicaba, São Paulo, Brazil).
KNO ₃	N	I. Friedman and J. O'Neil.

The so-called PBD standard consisted of a CaCO₃ obtained from a belemnite of Peedee formation of South Carolina. Its ^{13}C and ^{18}O contents are supposed to be close to the average contents of marine limestone. The PDB standard was first adopted in the early 1950s as reference in palaeotemperature studies.

than water. The proposed new reference samples, which will be kept at both IAEA and US National Bureau of Standards, are listed in Table 4. They will supplement the standards now being distributed by the US National Bureau of Standards which, in some cases, are insufficient in amount for a long-term worldwide distribution (as, for instance, the samples of nitrogen (NBS-14) and of SO₂ (NBS-120A), I. L. Barnes, personal communication).

SLAP was prepared by H. Craig, University of California at San Diego; GISP was provided by W. Dansgaard, University of Copenhagen. A list of laboratories participating in the stable isotope intercalibration is contained in the reprints of this article.

Silica oxygen isotopes in diatoms: a 20,000 yr record in deep-sea sediments

PALAEOTEMPERATURE determinations based on oxygen isotope composition of planktonic foraminifera are well established for Quaternary and Tertiary deep-sea sediments¹⁻⁴. Wide areas of the ocean floor, however, are lacking suitable calcareous fossils due to dissolution or unfavourable ecological conditions. Here we show that isotopic analyses of diatom frustules can adequately substitute for the analyses of calcareous microfossils. To test the efficiency of diatoms as an isotopic palaeothermometer^{5,6}, we compare the oxygen isotope records of diatoms and of planktonic foraminifera in a box-core from the eastern equatorial Pacific (PLDS 72, latitude 01°08'N; longitude 109°15'6''W; water depth 3,626 m). This core was among other box-cores raised during the S.I.O. Pleiades expedition between May and September 1976, in an effort to obtain undisturbed samples of the uppermost deposits in this fertile area of pelagic sedimentation.

Isotope analyses of the planktonic foraminifera followed

standard procedures⁷ and the reproducibility of the oxygen isotope values is about $\pm 0.1\%$. All box-cores were routinely assessed isotopically at Scripps Institution of Oceanography to establish stratigraphic continuity.

The preparation of biogenous silica for isotopic analysis requires considerably more effort than that of calcareous materials. The diatoms are separated from carbonate, radiolarians and detritals by HCl treatment, ultrasonication, sieving (fraction larger than 22 μm retained) and differential settling. The process further requires a complete cleaning of the silica which removes all extraneous materials as organic coatings and hydration water. A new method has been developed for this process which calls for 2 weeks of oxidation with 0.1M KMnO₄, 1 week of desiccation with P₂O₅ and partial recrystallisation under vacuum at 800–1,000 °C (ref. 8). Compared with an earlier cleaning method on recent diatoms and sponge spicules^{5,6}, a +7‰ isotopic shift was observed using the improved cleaning procedure on oceanic siliceous ooze. This shift is reproducible for replicate treatments. The lower δ values obtained by the first cleaning procedure are presumably due to residual organic carbon and hydration water reacting with the silica during the high temperature heating. Results to be published elsewhere⁹ show that although the magnitude of the fractionation factor between silica and water is changed by the more complete cleaning, this does not seem to affect the variations with palaeotemperature of the isotopic fractionation. Thus, while the scale for the absolute values of the silica $\delta^{18}\text{O}$ shifts as a function of preparation, the shape of the stratigraphic isotope signal would remain unchanged. The final cleaning and the isotopic analyses were made at Centre des Faibles Radioactivités, C.N.R.S., France. Reproducibility of the isotope values was 0.1‰.

Results show an overall parallelism between the oxygen isotope records of diatoms and of the planktonic foraminifera (Fig. 1a and b). The exact time span of the record is not known, but is immaterial for the present discussion. An age of 18,000 yr for the $\delta^{18}\text{O}$ maxima⁹ near a core depth of 34 cm yields an average sedimentation rate of 1.9 cm per 1,000 yr which seems reasonable for this area. Thus, the 40 cm long core represents about 20,000 yr. The oxygen isotopes show high values in the older sediments and low values in the younger ones, reflecting the familiar transition from glacial to Holocene time. The overall range from high to low $\delta^{18}\text{O}$ values is greater for the diatoms ($\sim 1.5\%$) than for the foraminifera ($\sim 1.2\%$). The transition may be uneven^{7,10} although the exact nature of this unevenness is obscured by mixing processes.

The oxygen isotopic ratio of planktonic foraminifera in deep-sea sediments is a function of the temperature and the

isotopic composition of the water in which they developed. Part of the development can take place within the thermocline, and the average depth of the shell precipitation is thus an important factor. The isotopic composition of seawater depends on the amount of continental ice^{1,3,12} and also on the evaporation/precipitation ratio, that is, regional salinity. The interpretation of oxygen isotope values is further complicated by preferential dissolution on the sea floor of isotopically lighter shells⁷. The magnitude of these various effects has been reviewed elsewhere¹¹. Analogous effects may be expected for diatoms, except that these photosynthesising, shallow-living algae preferentially develop their skeletons within the mixed layer of the ocean. Depth of growth may, therefore, be ruled out as an important factor. Seasonal changes of temperature and changes in the evaporation/precipitation ratio will affect diatoms as much as foraminifera. Direct input of melt water could conceivably produce a differential effect on diatoms in pericontinental and high latitude waters. Any such differential is thought to be insignificant in the area under study.

The deglaciation effect accounts for most of the foraminiferal isotopic range (Fig. 1b) being approximately 1.2‰ in magnitude^{3,12}. It should influence the diatoms in a similar way. Which other effects are then responsible for the measured 0.5‰ difference (Fig. 1c) in the isotopic range between the diatoms and foraminifera?

An effect of temperature is certainly possible, if the surface water inhabited by the diatoms experienced more warming than the deeper waters inhabited by the foraminifera *Neogloboquadrina dutertrei* and *Pulleniatina obliquiloculata*. *P. obliquiloculata* secretes its shell mostly in subsurface waters whereas *N. dutertrei* typically occurs in upwelling regions and hence reflects a strong influence of cold subsurface water in its composition. Of the other possible effects two deserve special attention: a change in species composition of the diatom assemblages (season effect) and changes in the preservation of the siliceous and calcareous microfossils (dissolution effect).

With the beginning of the post glacial, upwelling seems to have been reduced in the Equatorial Pacific¹³. The abundance of *Thalassionema nitzschioides*, a diatom species especially confined to areas of upwelling, is reduced at this point. The composition of the diatom assemblages otherwise remains virtually constant throughout the core interval and any seasonal influence on the isotopic values, therefore, seems negligible.

Differential dissolution of the less silicified warm-water frustules of diatoms can enrich an assemblage with cold-water forms¹⁴ and conceivably disturb the isotopic signal. In the present case, there is no evidence for interference from such dissolution effects. Dissolution has affected certain core levels but there is no great difference between diatom preservation in glacial and post-glacial sediments in this core (Fig. 1e).

There is evidence, however, that the foraminiferal signals have been affected by differential dissolution. In the present case, such dissolution would decrease the range of the foram signal, as it removes isotopically light shells from post-glacial sediments⁷. A noticeable divergence of the signals of *N. dutertrei* and *P. obliquiloculata* begins near 17 cm in the core. A similar divergence between two foraminifera species has been shown to mark the onset of the Holocene dissolution pulse 12,500 ¹⁴C years ago⁷. A decrease in per cent carbonate immediately follows (Fig. 1d). This level also corresponds to the divergence of the diatom and foraminiferal isotope signals (Fig. 1c).

It seems, therefore, that two effects are important in producing a difference in isotopic ranges between diatoms on one hand and foraminifera on the other: (1) a greater temperature sensitivity of diatoms (because they live in surface waters) and (2) a reduction in the foraminiferal isotopic range (due to the Holocene carbonate dissolution). If differential warming of surface and subsurface water could entirely account for the discrepancy between diatoms and foraminifera, surface waters would have warmed more by 1.5 °C, about one half of the total warming calculated by CLIMAP⁹ for this area. But the difference could also be a reflection of carbonate dissolution so that the

Fig. 1 Variation with depth in Core PLDS 72 Bx from the eastern Pacific of: a, $\delta^{18}\text{O}$ SiO_2 against SMOW of clean diatom valves after oxidation of organic matters with KMnO_4 , desiccation by P_2O_5 and high temperature heating (analyses by L. Labeyrie). b, $\delta^{18}\text{O}$ CaCO_3 against PDB of two foraminifera species: *Pulleniatina obliquiloculata* (dashed line) and *Neogloboquadrina dutertrei* (solid line) (analyses by J. S. Killingley and E. Vincent). c, Calculated $\Delta(\delta^{18}\text{O} \text{ SiO}_2 - \delta^{18}\text{O} \text{ CaCO}_3)$ (*N. dutertrei*). The reported Δt has been calculated from: $\Delta t \sim 4\Delta(\text{SiO}_2, \text{H}_2\text{O}) \sim 4\Delta(\text{CaCO}_3, \text{H}_2\text{O})$ (8) where zero is the mean value for the 18–40 cm depth range. d, Carbonate abundance, in per cent of weight. e, Diatom Preservation Index, a measure of the morphological change of the diatom valves caused by dissolution (analyses by N. Mikkelsen). In the relatively poorly preserved interval around 20 cm, dissolution resistant species like *Coccolithus nodulifer* and *Ethmodiscus rex* are concentrated¹⁶.

differential warming would be negligible.

In conclusion, the present study has shown the possibility of using the silica $^{18}\text{O}/^{16}\text{O}$ ratio in diatom valves as a palaeo-temperature indicator. The similarity between the diatom and foraminifera signals indicates that no isotopic re-equilibration between the diatom silica and the bottom water takes place. This is in contrast to findings by Mopper and Garlick¹⁵ who may have used inadequately cleaned samples. Comparison of $^{18}\text{O}/^{16}\text{O}$ ratios in diatoms and foraminifera from the same core may allow observation of changes in the thermal stratification of the oceans. The isotopic composition of diatoms will be a unique temperature tracer in high latitudes where shallow-dwelling foraminifera are commonly lacking in sediments. The isotopic composition of the diatom valves should also make it possible to extend the oxygen-isotope stratigraphy to deep-sea sediments below the compensation depth for calcium carbonate.

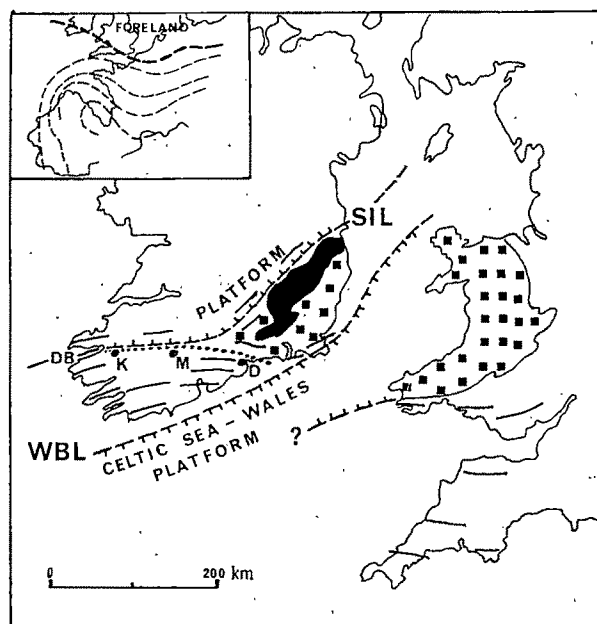

Fig. 1 Sketch map of Hercynian fold trends in Southern Ireland and south-west Great Britain. Blocked areas represent Lower Palaeozoic massifs, with the Leinster pluton and its concealed extension shown in solid. Dotted line indicates position of Hercynian Front in Ireland^{13,15}. SIL, South Ireland Lineament; WBL, Wexford Boundary Lineament; DB Dingle Bay; K, Killarney; M, Mallow; D, Dungarvan. Data sources from refs 14,25,26. Inset map showing location of Hercynian orogenic zones in Western Europe^{11,12} on a pre-Permian reconstruction²⁷.

Is the Hercynian Front in Ireland a local feature?

THE boundary of the northern foreland with the Hercynian orogeny in Europe—the Hercynian Front—has been recognised as a major feature in European palaeotectonic reconstructions^{1,2}, in transatlantic correlations³⁻⁷, and for metallogenic models⁸⁻¹². In all these assessments the Hercynian Front (or Thrust Front) is depicted as a structural line transecting southern Ireland on a crudely east-south-east (Armorican) trend across to South Wales. It is suggested here, however, that the 'Front' in Ireland has no direct link with South Wales, being separated by a major basement block, and may well be a localised internal foreland feature.

The position of the Hercynian Front in Ireland is based on the perceptive study by Gill¹³, who recognised a marked change in tectonic style across an arcuate line from Killarney to Dungarvan, part of which consisted of northerly directed thrusts. This he termed the Thrust Front, which was subsequently^{14,15} modified to continue westwards through Dingle Bay (Fig. 1). The acceptance of the line of the 'Front' here has led to recent attempts to trace it off the west coast of Ireland¹⁶ and to suggest a link with the Gibbs Fracture Zone^{5,6}.

An examination of the Hercynian fold trends in southern Ireland¹⁴, however, reveals three aspects at variance with the popular conception. First, south of the 'Front' the folds show an arcuate trace markedly divergent from the east-south-east Armorican trend except in the Dungarvan area; second, from Dungarvan eastwards the trend rotates back to an east-north-east direction (Fig. 2), negating the simple east-south-east extrapolation directly to South Wales; and third, the strike of Hercynian structures in the south of Ireland show close agreement with Lower Palaeozoic structural trends except to the north of Dungarvan, and hence can be regarded as having a Caledonoid trend rather than an Armorican one.

On this basis the concept of an Armorican trending Hercynian imprint on the south of Ireland, which transects

earlier Caledonoid trends and can be matched directly with that of south-west Wales and south-west England, cannot be upheld. Rather, the Hercynian structural pattern here is considered to have been locally basement controlled, and to reflect the influence of three major basement elements which resulted in contrasting 'platform' and 'basin' (graben) deformation¹⁷. These major elements are the South Ireland Lineament, the Wexford Boundary Lineament, and the Leinster pluton (Fig. 1). These two lineaments, which parallel Caledonoid structures, have been recently recognised as major temporally persistent palaeo features, influencing lower Palaeozoic deposition and deformation¹⁸ as block boundaries. Between, and controlled by, these two lineaments there was subsequently a thick Upper Palaeozoic accumulation (>4,000 m) in a structural basin¹⁹, thinning dramatically eastwards onto the positive block of the Caledonoid Leinster unit stiffened by its mid-Devonian pluton (Fig. 2).

Because of this eastward shallowing basement in the sector between the two lineaments, Hercynian compression here resulted in two differing structural provinces, a south-west 'graben' province, and a north-east 'platform' province. The former shows polyphase fold deformation^{13,20} with tight major fold structures and a locally penetrative cleavage fabric, together with severe northerly directed thrusting and structural dislocation in the Killarney-Dingle Bay area^{15,20} along the margin of the block delineated by the South Ireland lineament, and also further south at Kenmare²⁰ and Bantry (Gardiner, unpublished). Folds parallel the Caledonoid trend of this lineament, predictably swinging to an east-south-east orientation as deformation was influenced by the positive Leinster block¹³ in the Mallow-Dungarvan area. In contrast, in the Leinster platform area the Upper Palaeozoic cover shows only broad open folds due to the basement protection, and the folds are moulded against the Leinster pluton (Fig. 2). Post-Caledonoid flexing of the Lower Palaeozoics in south-west County Wexford²¹ and the inferred present day strike

swings of the two lineaments are also thought to be due to late stage Hercynian tightening against the rigid Leinster pluton.

In this structural model the northern boundary of the zone of 'graben' deformation therefore has an arcuate trace (Fig. 1) which is essentially the line of the recognised 'Thrust Front'¹¹⁻¹⁵. The major tectonic dislocations recorded at Mallow and further west^{13,15} seem, however, to be relatively localised features reflecting proximity to the edge of the northern positive block. Their apparently problematical absence east of Mallow is entirely predictable on this model, as this was a transitional zone between the 'graben' and 'platform' deformation areas, with deformation intensity decreasing northeastwards due to the progressive basement influence of the lower Palaeozoic Leinster block. This factor was recognised by Philcox²², who suggested that east of Mallow the 'Thrust Front' was split into a number of fanned 'arms' as it was accommodated by the Upper Palaeozoic cover above interfering basement units. Certainly there is no one continuous 'Thrust Front' in this area²³, as was earlier proposed¹³, and use of this term here would seem unsuitable.

Recognition of a positive basement block between south-east Ireland and South Wales during the Hercynian orogeny also creates problems in any simple linkage of the Hercynian Front between these two areas. Indeed, the Welsh Lower Palaeozoic massif seems to have also been part of this intervening structural platform, as the Hercynian fold trends in South Wales seem to have been influenced by the arcuate southern margin of the massif²⁵ (Fig. 1). The 'Thrust Front' position in south-west Wales is also a reflection of basement-cover interaction^{4,24}, although its position further southeastwards is by no means clear²⁵.

It is, therefore, concluded that there is no continuous linkage between the Hercynian Front in south-west Wales and Southern Ireland, in both areas its location and trend

being a function of basement control; simple metallogenic correlations are, therefore, improbable. Transatlantic correlation seems likely to relate to pre-Hercynian structural elements, and will depend on whether the western continuation of the 'Front' with the northern foreland is in fact along the South Ireland lineament or the southern margin of the Celtic Sea-Wales platform block (Fig. 1). If the latter, then the 'Thrust Front' in Ireland is perhaps a localised internal foreland feature. Certainly recent work off the west coast of Ireland¹⁶ indicates that the Gibbs Fracture zone is better related to the Great Glen Fault line rather than to the 'Hercynian Front' in Ireland. The inferred westerly closing of the other Hercynian orogenic zones in Western Europe when plotted on a pre-Permian reconstruction^{11,12} (Fig. 1, inset) would also accord with a continuation of the true Front southwestwards from south-west Wales. There is no evidence of proximity to a plate boundary directly off the south of Ireland, and the inferred evolutionary history of this area^{18,19} indicates that in Hercynian times there was no oceanic crust north of the Celtic Sea-Wales platform.

Song repertoires and territory defence in the great tit

BIRD song is generally considered to have one or both of two main functions: attracting a mate and proclaiming a territory. The great tit (*Parus major*) is a typical songbird in that song is primarily a male vocalisation and it is produced before and during the breeding season (that is, from January to May in southern England). We have shown that great tit song plays a part in territory maintenance by experiments in which we 'occupied' territories with loudspeakers after removing resident pairs^{1,2}. New pairs seeking an empty space in which to settle moved into control areas more rapidly than into song-occupied territories. We report here on three experiments designed to study the effect of a varied song repertoire in territory maintenance. Each male great tit, in common with many other songbird species, has a repertoire of song variants some of which are usually shared between birds in a locality. In the great tit, repertoire size commonly varies between two and eight song types. In some species, for example the canary, elaborate repertoires seem to be favoured by sexual selec-

Table 1 Results from Marley Wood near Oxford showing that there is no evidence for female choice of males with large repertoires

Year		Repertoire size	
		1-3	4-6
1975	<i>N</i>	27	4
	Laying date*	31.9 \pm 0.62	35.6 \pm 3.5
	Clutch size*	7.7 \pm 0.21	7.3 \pm 0.5
	Per cent adult	59	50
1976	<i>N</i>	8	5
	Laying date	32.7 \pm 2.03	28.6 \pm 2.82
	Clutch size	8.1 \pm 0.44	8.2 \pm 0.58
	Per cent adult	75	60

This result is not surprising since females choose mates before the spring peak of male song. If females did prefer males with larger repertoire sizes, one would predict a correlation between repertoire size and breeding date or female fecundity. The age-corrected data show no such trend. The table also shows that males with larger repertoires do not tend to be older.

*Corrected for age of ♀

†Time in days after April 1.

tion^{3,4}, but we have found no evidence for this in the great tit (Table 1), in which pairing takes place before the spring peak of song. We therefore tested the possibility that repertoires enhance the effectiveness of song as a territorial display.

The three experiments were all of similar design. We plotted the territories of all the pairs (which were colour ringed) in a 6 hectare piece of mixed deciduous woodland² (Higgins Copse) near Oxford in early spring. In each experiment the wood was divided into three areas: control, single song and repertoire. At the start of an experiment we captured (under licence) all the resident birds in the wood during the first two or three hours after dawn on one day. The control area was left empty, the single song and repertoire areas were occupied by loudspeakers broadcasting either a single song type or a varied repertoire of songs. The broadcasting system consisted of a Uher 4000 IC tape recorder equipped with a 'Cousino' endless loop tape linked by a 15-W amplifier to four Goodman's Midax

metal horns. Each metal horn was located 50 m from the tape recorder in a different part of the 'occupied' territory. The system was powered by a 12 V battery and it operated on a time schedule controlled by a Crouzet 24 h time clock linked to a Crouzet 30 min cam timer.

The timer was set so that song was played for two minutes from each of the four loudspeakers in turn (a total of eight minutes of song). The eight minute cycle was triggered by the 24 h time clock at intervals throughout the day from dawn till dusk. During the first 3 h after dawn, the cycle was triggered once every 30 min, and for the rest of the day once an hour (simulating the natural morning peak of song). In experiments *a* and *c* (Table 2) there was one broadcasting set-up in each experimental territory; in experiment *b*, the wood was simply divided into three areas without regard to the previous territory boundaries, and the two experimental areas were occupied by a single tape recorder linked to six loudspeakers. To control for variations in attractiveness of different parts of the wood, we altered the positions of the treatment areas between experiments.

The broadcast songs were recorded from the local birds which had previously occupied territories in the wood, or from birds occupying territories in a nearby wood. We had previously made a comparison of the effectiveness in deterring invaders, of songs from within the wood and songs from nearby woods, and found that there was no difference: in four paired comparisons occupied by 'native' and 'nearby' repertoires, the following results emerged; on one occasion, the territory occupied by native songs was invaded first, on another, the other territory was invaded more quickly, and on two occasions there was no difference in latency to occupation. The repertoires used in the present experiments consisted either of local birds' song or a mixture of local and other birds' songs, and in the single song treatments we used local birds' songs.

Throughout each experiment, the pattern of reoccupation of the wood by newcomers was monitored by continuous observation from dawn till dusk. The locations of all new birds were marked on a map with reference to grid posts, and all parts of the wood were visited at least once each hour. The experiment was deemed to have ended when the

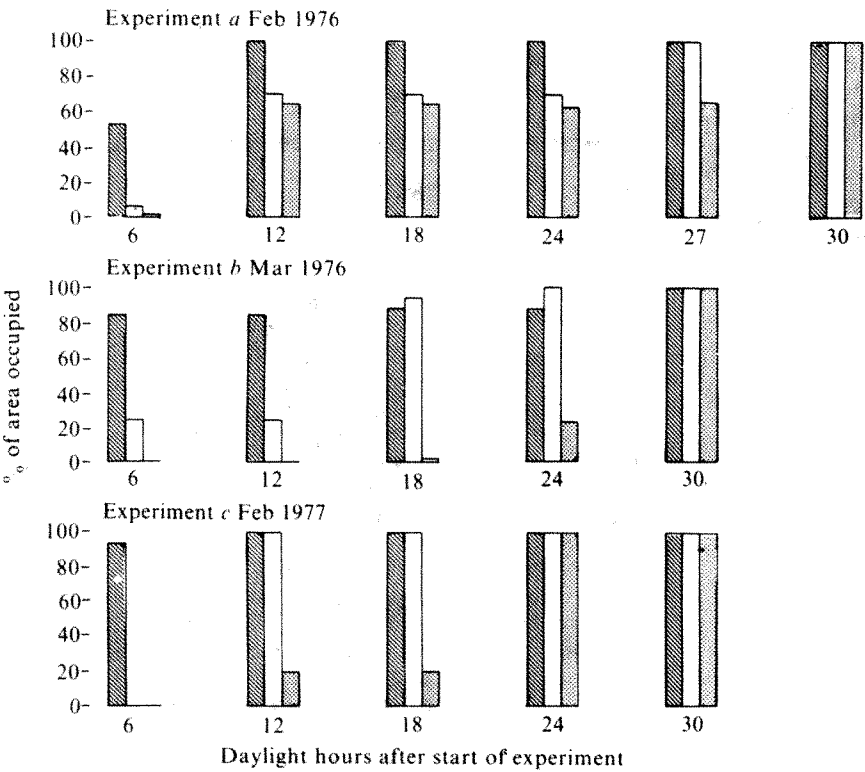

Fig. 1 A summary of the results of the three experiments. The graphs show the cumulative proportion of the three areas occupied since the start of the experiment after different numbers of daylight hours. Cross-hatched columns, control; open columns, single song; stippled columns, repertoire.

Fig. 2 The difference (in daylight hours) in the time to 90% occupation of repertoire and single song areas in relation to repertoire size. The vertical bars are standard errors. The reason for plotting the difference rather than absolute time for occupancy is that the total time span of the experiment differed between the three replicates. We took 90% of the area occupied as a criterion of 'occupation' because it was impossible to distinguish in our observations between 90% and 100% occupancy.

wood was completely occupied by new birds, at which point the speakers were turned off.

The results are summarised in Figs 1 and 2, and Fig. 3 shows an example of the reoccupation pattern over successive days. Figure 1, in which we plot the cumulative proportion of the wood occupied by new birds as a function of time, shows that in all three experiments the sequence of reoccupation of areas was: control, single song and repertoire. The three experiments were performed with repertoires of different sizes spanning the normally occurring range: 3, 9 and 6 in experiments *a*, *b* and *c*, respectively. Figure 2 shows that the difference between the time to 90% occupation of the repertoire and single song areas increases with increasing size of repertoire. We suggest that song repertoires enhance the effectiveness of song as a 'keep out' signal, and that larger repertoires are more effective than small ones. In view of this latter finding, it is surprising that the commonest repertoire sizes in our study area are 3 and 4 song types.

One or both of two mechanisms might account for our results. First, the various songs in the repertoire could be used in slightly different contexts. Three possible contexts are: time of the year, position in the territory, and the particular rival at whom the song is directed. We tested

whether or not birds use different song types at different stages in the season of territory establishment by comparing the relative frequency of use of songs during two sample periods separated by about two weeks (late January versus mid-February for three birds, and late February versus mid-March for three others). The correlation coefficient based on all six birds was highly significant ($P < 0.001$), suggesting that relative frequency of use of songs in the repertoire does not vary with season. We also did a similar correlation analysis of the relative use of different song types in different parts of an individual's territory by dividing each of the same six territories arbitrarily into north and south halves: again the correlation was highly significant ($P < 0.001$). This analysis was performed because the different songs in a repertoire might be adapted for use in the specific acoustic climate of different parts of the territory, and it is still possible that a more detailed analysis would support this idea, although our present results do not. One contextual factor which does influence the use of song types in a repertoire is the song of intruding rivals: resident birds tend to match the songs of intruders (J.K. & R.A., in preparation). Matching seems to act as a way of indicating that the song is directed at a particular intruder (who then retreats), and clearly a bird with a repertoire of songs is better able to match. This was not a major contribution to our results, however, as the loudspeakers in our experiments were not specifically programmed to match the songs of invaders.

The second mechanism which might account for our results is the so-called Beau Geste effect³. It is based on the fact that, as our experiments show, birds attempting to establish a territory use song as a cue in choosing where to settle. Reproductive success in woodland in the great tit

Fig. 3 An example of the results of one experiment (experiment *b*). The four maps show the sequence of reoccupation of the wood and the division of the wood into three treatment areas. Key: broken lines, division into treatments; large dots, new territorial pair in control area; small dots, new pair in repertoire area; cross-hatching, new pair in single song area; *a-f* represents the sequence of arrival of the new birds (*b* disappeared after day 2). Scale 6 mm, 50 m.

Table 2 A summary of the three experiments reported in this paper

Experiment	Date	No. of territories before			No. of pairs reoccupying the wood
		R	S	C*	
<i>a</i>	Feb 23-25 1976	3	2	3	4
<i>b</i>	Mar 15-18 1976	4†			4
<i>c</i>	Feb 15-18 1977	2	2	2	6

*Repertoire, single song, control.
†In this experiment the 3 treatments were assigned without regard to previous boundaries (see text).

Table 3 Data showing that a male is much more likely to change song perches at the same time as changing song types

Probability of changing perches N	Next song burst	
	Same song type	Different song type
	0.035	0.44
	1,755	18
	$\chi^2 = 79.95$	

The data were collected in an open parkland area (University Parks, Oxford), and changing song perches was defined as changing trees (the birds often hop about continually within a tree). The data only refer to changes in perch or song type within a period of song (that is, the bird did not pause for longer than 30 s between song bursts).

is negatively correlated with density⁶, so a settler should avoid crowded woodlands. Residents might therefore discourage invaders by singing several different songs, and creating the impression of a crowded habitat. The fact that territorial birds tend to change perches when they change song type (Table 3) is consistent with this ideal. Of course the deception we are proposing would only work to the extent that potential settlers do not correct for repertoire size.

We thank the S.R.C. for financial support, M. Dolan and D. Morris for building apparatus, and Nick Davies for helpful comments on the manuscript.

Tolerance of *Triticale*, wheat and rye to copper deficiency

THE aim in producing *Triticale* was to combine the hardiness and tolerance of low soil fertility of rye with the superior yield and bread-making qualities of wheat¹, but there has been little experimental evidence that triticales carry the desirable characteristics from rye². We present here evidence of the tolerance of triticales to low concentrations of available copper in soil, a condition widely associated with poor sandy soils in Australia³. Such soils may contain enough total copper for tens of thousands of crops but it is relatively unavailable to widely grown cultivars of wheat, oats and barley. In contrast, rye rarely shows a response to copper on these soils⁴⁻⁷.

Triticales are hybrids of wheat and rye and there are two major classes: hexaploids, the most promising agriculturally, are derived from crosses between diploid rye (*Secale cereale*) and tetraploid wheat (*Triticum durum*), and octoploids come from crosses between rye and hexaploid wheat (*Triticum aestivum*). In our study a hexaploid triticales and an octoploid triticales and their parent genotypes were grown in pots of copper-deficient soil with four levels of copper supplied. Chinese Spring wheat and Imperial rye are known to be the parents of the octoploid triticales⁸ but the parents of the hexaploid triticales Beagle are not known, it having resulted from crosses between many parent genotypes⁹. Accordingly, the genotypes chosen to represent the parents of the hexaploid in our study are approximate only, though

certainly, together with Chinese Spring, their response to the level of copper supplied is characteristic of their species⁴⁻⁷.

Grain yields for each of the five genotypes at each level of copper are shown in Table 1. Both wheats were extremely sensitive to the level supplied, producing no grain without supplementary copper. In contrast, rye and the hexaploid triticales were remarkably tolerant of this soil, producing as much grain in untreated soil as when copper was added. The mean grain yield of the Imperial rye was unusually low because of its poor adaptation to the environment; it matured four weeks later than the other genotypes under high temperatures and consequently grain numbers were low and grain size was small although, like grain yield, neither grain number nor size responded to copper application.

Clearly hexaploid triticales has followed its rye parentage in its tolerance of low copper supply; its yield without added copper was comparable to that of wheat in soil with the highest level of added copper. The most immediate explanation for the gross differences in response to copper supply seems to be male sterility. Copper deficiency causes male sterility in wheat¹⁰ and both pollen viability and grain number (D. T. Pearce and R.D.G., unpublished results) have shown the same pattern of response to copper supply as did grain yield (Table 1).

The difference in response of wheat and rye in copper-deficient soils is due to the ability of rye to maintain a higher concentration of copper in the shoot^{4-7,11}. Concentrations of copper in triticales seem to be intermediate between wheat and rye (unpublished results) but sufficient to maintain the plant above the threshold which prevents male sterility. Rye has a more extensive root system than wheat¹² but the higher levels of copper may be due to a more specific character than size of root system because in a study by Piper and Walkley¹¹, rye contained more copper but not more zinc.

Rye and triticales may thus be termed copper-efficient and wheat copper-inefficient. The difference in the responsiveness of octoploid and hexaploid triticales may reflect the degree of buffering of copper efficiency of the rye genome by different numbers of wheat genomes. Two genomes of tetraploid wheat retain high efficiency whereas three

Table 1 Effect of copper supply and genotype on yield of grain in a copper-deficient sandy soil

Genotype	Ploidy	Copper supply (mg per pot)			
		0	0.1	0.4	4.0
		Grain yield* (g per pot)			
<i>Triticum durum</i> cv Cocorit	Tetraploid	0	0.1	5.6	12.5
<i>Triticum aestivum</i> cv Chinese Spring	Hexaploid	0	3.5	12.9	13.7
<i>Secale cereale</i> cv Imperial	Diploid	2.1	2.4	2.4	2.1
<i>Triticale</i> cv Beagle	Hexaploid	14.3	13.8	14.3	14.5
<i>Triticale</i> Chinese Sp.-Imperial	Octoploid	4.6	6.5	7.4	7.5

*Each value is the mean of three replicates. Plants were grown in a copper-deficient siliceous sand from Tintinara, South Australia (Laffer Sand) in an evaporatively cooled glasshouse. Each pot contained 12 kg of soil which supported three plants. Appropriate amounts of nutrients N, P, K, Ca, Mg, S, Fe, B, Mn, Zn, Mo, Co and Cl were added with or without Cu. Of the genotypes, only wheat plants failed to grow normally in the soil without added Cu, showing characteristic symptoms of wilting, delayed maturity and failure to set grain¹⁰. The copper responses of both wheats and the octoploid triticales are significant at $P = 0.001$.

genomes of hexaploid wheat reduce the efficiency to a position intermediate to hexaploid triticale and hexaploid wheat.

Several nutritional characters have been shown to be under single-gene control, for example, iron efficiency in soybeans¹³ and boron efficiency in tomato¹⁴, and this may also be the case for copper. Pugsley (personal communication) in a hybridisation study of copper-efficient oats (*Avena strigosa*) and copper-inefficient oats (*A. sativa*) has found copper efficiency to be controlled by one or two genes. Triticale cultivar Beagle used in my study contains the complete rye genome of seven chromosome pairs⁹, but studies in progress suggest that copper efficiency is carried on a single rye chromosome, and if this is so, it should be possible to translocate the relevant part of the chromosome to wheat to produce a copper-efficient line of wheat.

Copper efficiency from rye is transferable to triticale and the potential of this new crop for marginal lands deserves further examination. The mechanism of enhanced copper utilisation is important too, for if it is linked with the morphology of the root system, it may influence the utilisation of other immobile soil nutrients.

Activation of an endogenous retrovirus from *Tupaia* (tree shrew)

TYPE-C RNA viruses have been isolated from tissues and cell lines of various mammalian species, including mice^{1,2}, domestic cats³, pigs^{4,5}, woolly monkeys^{6,7}, gibbons⁸ and squirrel monkeys⁹. The viruses from woolly monkeys seem to be horizontally transmitted as infectious agents which cause naturally occurring tumours in gibbons⁷. Apart from the known aetiological role of certain oncornaviruses in the formation of neoplasms, there has been increasing interest in the isolation of mammalian retroviruses and their evolutionary relatedness to different species. Experimental evidence suggests that during evolution an endogenous virus crossed from one species to another¹⁰. *Tupaia* (the tree shrew), a member of the family Tupaiidae, is regarded as one of the most primitive living prosimians, bridging the gap between insectivores and primates^{11,12}. We report here the detection and activation, *in vitro* and *in vivo*, of an endogenous retrovirus from *Tupaia*. This opens up the possibility of a direct comparison of the *Tupaia* retrovirus with type-C viruses from rodents and primates.

Reports^{13–15} on type-C RNA viruses in placentae of normal, healthy Sprague-Dawley rats initiated a search for an analogous *Tupaia* virus in placentae of healthy, untreated animals and others treated with iododeoxyuridine (IUDR) 24 h before the end of pregnancy. We used *Tupaia belangeri* Baf: BIAS (Baf designates the breeder, the Battelle-Institut, Frankfurt and BIAS is the name of the stock used¹⁶). Placentae were

removed aseptically from untreated, healthy, pregnant *Tupaia* at full term and prepared for electron microscopy. Figure 1 shows an electron photomicrograph of virions, which in size and structure are morphologically similar to type-C virus particles. Figure 1b shows a budding virus particle; some virions have spike-like structures consistent with reports that the ultrastructure of type-C virus particles varies considerably^{17,18}.

We took a more direct approach by establishing *Tupaia* fibroblasts from skin of single embryos or juvenile animals in tissue culture. Some cultures were treated with IUDR to activate retrovirus. We describe here the experiments with the cell cultures derived from the second embryo of one animal (no. 458, TEF-458-2). The cells were established and propagated in tissue culture as before¹⁹. They were grown at 37 °C and treated with IUDR in the replication log phase of cell growth. After treatment with IUDR (50–200 µg ml⁻¹) for 24 h several clones were isolated and established in tissue culture. Treatment of *Tupaia* fibroblasts with 200 µg IUDR per ml of medium had no highly toxic effect within 24 h. The plating efficiency of the treated cells (measured according to Ham²⁰) decreased to 17% that of untreated cells and was 22.5%. The supernatants of the different cell clones were assayed for reverse transcriptase activity^{21,22}. Poly (rA)·(dT)₁₄ served as template/primer; poly (dA)·(dT)₁₄ was used as a control²³. The incorporation of ³H-dTMP was maximal in the presence of 0.5 mM Mn²⁺ as divalent cation (Fig. 2). In the presence of poly (dA)·oligo (dT) only small or negligible levels of RNA-directed DNA polymerase (RDDP) activity were observed. RDDP activity detectable with poly (rA)·oligo (dT) was inhibited by 2 mM inorganic phosphate, which is characteristic for mammalian virus DNA polymerase²⁴. Low levels of ³H-dTMP incorporation were observed in supernatants of *Tupaia* cell cultures not treated with IUDR, whereas an increase

Fig. 1 Electron micrographs of ultrathin sections of *Tupaia belangeri* placenta. The placenta tissue was fixed in 2% glutaraldehyde, buffered with 0.05 M sodium cacodylate, pH 7.2, in the cold for 20 min, followed by several washes with cold buffer and osmication in the cold (2% osmium tetroxide). The material was dehydrated through graded ethanol solutions and embedded in Epon 812. *a*, Virus particles in *Tupaia* placenta (the bar represents 200 nm). *b*, Virus particle budding like type-C virus from *Tupaia* placenta (the bar represents 100 nm); the centrally located nucleocapsid is in direct contact with viral envelope (the bar represents 100 nm). *c*, The cylindrical particle has an internal structure similar to that of the immature type-C particle. *d*, Extracellular, immature virus particle (the bar represents 100 nm).

Fig. 2 Kinetics of polymer synthesis with reverse transcriptase from supernatants of TEF-458-2-J-2 cell cultures using poly (rA)·oligo (dT) (●) or poly (dA)·oligo (dT) (▲) as template/primer. The reaction mixtures (0.10 ml) consisted of 50 mM Tris-HCl, pH 8.1, 30 mM KCl, 0.5 mM MnCl₂, 1 mM dithiothreitol, 0.08 mM dTTP including ³H-dTTP (Radiochemicals Centre, Amersham, specific activity 62 Ci mmol⁻¹), poly (rA)·(dT)₁₄ at 48 μM (Collaborative Research, Waltham, Massachusetts). Reactions were started by the addition of 60 μl viral suspension (disrupted by Nonidet P-40 for 10 min at 24 °C) to the polymerisation mixtures. Reactions were carried out at 37 °C and monitored as described before²³.

in RDDP activity was observed routinely in cultures treated with halogenated pyrimidines (Table 1). All cell cultures used for the DNA polymerase assays (Table 1) were of either the same or nearly the same passage level.

To activate retrovirus *in vivo* from *Tupaia*, a pregnant animal (no. 944, 205 g body weight) was injected intraperitoneally with IUdR (10 μg per g body weight) on the 35th day of gestation—the normal period of gestation being 44 ± 1 d. Embryo no. 3 was removed aseptically by caesarean section 24 h later, and skin fibroblasts were explanted and

established in culture. RDDP activity (Table 1) revealed an increase in ³H-dTMP incorporation for TEF-944-3-J compared with the low levels found in supernatants of TEF-944-1 cultures derived from embryo no. 1 which had been removed before the injection of the mother animal no. 944 with IUdR.

To detect viral RNA we used ³H-uridine (specific activity 58 Ci mmol⁻¹). After phenol extraction²⁵ a peak of radioactivity banded at 70S after 5–20% sucrose gradient centrifugation (RNA from Gross strain of MuLV served as marker). When subjected to heat denaturation (3 min at 100 °C with 2% sodium dodecyl sulphate) the 70S RNA was converted into a broad peak centred around 35S. Furthermore, ³H-uridine-labelled virions from supernatants of three *Tupaia* cell cultures (TEF-944-3-J, TEF-458-2-J-2 and TEF-458-2-J-2-J) were isolated after purification by low and high speed centrifugation and banded in 15–55% neutral sucrose gradient. The activity peak banded at a density of 1.15–1.17 g cm⁻³—characteristic for retroviruses²⁶ (Fig. 3).

In a host range study, the isolated *Tupaia* retrovirus (TRV-1) was inoculated into human embryonic lung fibroblasts (HELFI)²⁷, human foreskin fibroblasts (HFF-3)²⁸, marmoset skin fibroblasts (HF)²⁹, mink lung cells (Mv1Lu)³⁰ and dog thymus cells (Fcf2th)³⁰. RDDP activity was detected in culture fluid from inoculated canine cells only at a low level. Cocultivation of isolated *Tupaia* cell clones (TEF-944-3-J, TEF-458-2-J-2 and TEF-458-2-J-2-J) with XC cells³¹ did not result in syncytia formation. Cocultivation of XC cells with Fcf2th cells infected with TRV-1 resulted in the formation of multinucleated giant cells containing 10–20 nuclei. The lack of formation of giant cells after cultivation of producer cell clones (TEF-458-2-J-2, TEF-944-3-J and TEF-458-2-J-2-J) with XC cells could indicate that TRV-1 is not of murine origin. However, the lack of induction of XC syncytia does not rule out a murine origin for TRV-1, because some murine leukaemia viruses do not induce XC syncytia³². Cytotoxicity tests with *Tupaia* producer cell clones and anti SSV-1 sera gave negative results. This suggests that SSV-1-specific surface receptors are not present in the tree shrew cell clones.

The absence of RDDP activity in normal *Tupaia* cells, and the inducibility by IUdR of a retrovirus from three different tree shrew cell cultures, suggest that TRV-1 is an endogenous retrovirus. Our data represent the first isolation (as far as we know) of an oncornavirus in the primitive prosimian *Tupaia*.

†With poly (dA)·oligo(dT) as template/primer.

Figures show incorporation of ³H-dTMP (pmol per 30 min) at 37 °C into acid-insoluble product. Assays were performed as described in the legend to Fig. 2. Protein was determined according to Lowry's³³ method.

Fig. 3 Equilibrium gradient centrifugation of TRV-1 virions. Culture fluids from TEF-458-2-J-2 cells incubated with ^3H -uridine ($28 \mu\text{Ci ml}^{-1}$) were clarified by centrifuging at $1,000g$ for 20 min and centrifuged through a 5% (w/v) cushion of sucrose for 60 min at $25,000 \text{ r.p.m.}$ in a SW27 rotor. The pellet was resuspended in 0.1 M NaCl , 10 mM Tris-HCl , $\text{pH } 7.2$, and 1 mM EDTA and layered on a 5-ml linear 30–60% sucrose gradient in the same buffer. It was then centrifuged at $50,000 \text{ r.p.m.}$ in a SW65 rotor for 4 h at 4°C . The gradient was fractionated and each fraction was assayed for acid-precipitable radioactivity (●) and density (○).

F. Deinhardt for valuable discussion and critical comments and for XC, HFF-3 and HF cells; Dr C. Bergholz for Mv1Lu and Fc2th cells; Dr G. Hunsmann for the cytotoxicity test; Dr W. W. Franke for comments on the electron micrographs; Dr A. Schwaier for advice on the animal experiments, and Ms Ulrika Gramlich and Ms Renate Schulz for technical assistance.

5'-AMP is a direct precursor of cytokinin in *Dictyostelium discoideum*

ISOPENTENYLADENINE ($i^6\text{Ade}$) and closely related derivatives occur naturally either as free bases or as constituents of tRNA^{1,2}. Although these cytokinins have been detected in various organisms, it is still not clear whether they are produced by the degradation of tRNA or whether they are synthesised by some pathway not involving tRNA. A spore germination inhibitor, discadenine, isolated from *Dictyostelium discoideum* was found to be an $i^6\text{Ade}$ derivative with a 3-amino-3-carboxypropyl group in the 3 position³—the cells contained a large quantity of free $i^6\text{Ade}$, presumably a precursor of discadenine⁴.

Fig. 1 Thin-layer chromatography of the products synthesised *in vitro* using ^{14}C -isopentenylpyrophosphate in the absence (a) or presence (b) of the supernatant of nondialysed, boiled S-100. The reaction mixture contained 20 mM Tris-HCl ($\text{pH } 7.5$), 5 mM magnesium acetate, $0.05 \mu\text{Ci}$ of ^{14}C - Δ^3 -isopentenylpyrophosphate (57 mCi mmol^{-1} ; Radiochemical Centre), 0.5 mg of dialysed S-100 extract and $10 \mu\text{l}$ of the supernatant of nondialysed, boiled S-100 in a final volume of $100 \mu\text{l}$. After 60 min incubation at 27°C , $150 \mu\text{l}$ of ethylacetate was added and the mixture was then vigorously shaken and centrifuged. The resultant upper layer was spotted on a plate of silica gel (Merck) and developed (10 cm) with chloroform-acetic acid (9:1, v/v). Chromatograms were scanned with a radiochromatogram scanner (Packard 385). Slit width was 2.5 mm . The S-100 extract was prepared from late culmination cells of *D. discoideum* strain NC-4 as follows; 1 g of cells were ground with 2 g of alumina, and extracted with 5 ml of buffer A (10 mM Tris-HCl , $\text{pH } 8.0$, 10 mM magnesium acetate, 60 mM KCl , 1 mM EDTA , 6 mM 2-mercaptoethanol and 10% glycerol). The extract was centrifuged at $13,000g$ for 30 min and the resulting supernatant was then further centrifuged at $156,000g$ for 60 min. The supernatant obtained was dialysed overnight against two changes of buffer A (300 ml each). The supernatant of nondialysed, boiled S-100 was prepared by boiling the nondialysed S-100 ($25 \text{ mg protein ml}^{-1}$) for 2 min and centrifugation.

Fig. 2 Thin-layer chromatography of the products synthesised *in vitro* using ^{14}C -5'-AMP in the absence (a) or presence (b) of Δ^2 -isopentenylpyrophosphate. The reaction mixture contained 20 mM Tris-HCl (pH 7.5), 5 mM magnesium acetate, 0.05 μCi of $[\text{U-}^{14}\text{C}]$ 5'-AMP (538 mCi mmol $^{-1}$, Radiochemical Centre), 0.5 mM Δ^2 -isopentenylpyrophosphate and 0.5 mg of dialysed S-100 in a final volume of 100 μl . After 60 min incubation at 27 $^{\circ}\text{C}$, the reaction mixture was extracted with ethylacetate. The extract was subjected to thin-layer chromatography in chloroform-acetic acid (1:1, v/v) and then scanned as described in the legend to Fig. 1. Δ^2 -Isopentenylpyrophosphate was synthesised chemically by the method of Kandutsch *et al.*⁵.

These results led us to investigate the cell-free biosynthesis of $i^6\text{Ade}$ in this organism. We report here the existence of a cytokinin biosynthetic pathway not related to tRNA degradation, showing that 5'-AMP is the actual acceptor molecule for the isopentenyl group. Our findings suggest that the biosynthesis of cytokinin in higher plants may proceed in a similar fashion.

We first synthesised $i^6\text{Ade}$ in reaction mixture containing ^{14}C - Δ^2 -isopentenylpyrophosphate and crude extracts (S-100) of

Fig. 3 Gel filtration of the S-100 extract on a Sephacryl S-200 column. S-100 extract, containing 15 mg of protein, was applied to a Sephacryl S-200 column (1.5 \times 70 cm) which had previously been equilibrated with buffer B (50 mM Tris-HCl pH 7.5, 1 mM EDTA, 6 mM 2-mercaptoethanol and 10% glycerol). Elution was carried out with buffer B and 1.5 ml fractions were collected. $i^6\text{Ade}$ synthesis was assayed with the reaction mixture described in Fig. 2, except that 20 μl of each fraction was used instead of S-100. After incubation at 27 $^{\circ}\text{C}$ for 60 min, the reaction mixture was extracted with 150 μl of ethylacetate and 30 μl of the ethylacetate layer was counted in a Beckman, Model LS-200B, liquid scintillation counter in toluene-based scintillator.

D. discoideum at the stage of late culmination. As shown in Fig. 1, dialysed S-100 catalysed the formation of a radioactive material that coincided in position with the authentic $i^6\text{Ade}$ spot only when the supernatant of nondialysed, boiled S-100 was added. Essentially similar results were obtained with another solvent system (chloroform : methanol, 8 : 2, v/v). These findings suggest that $i^6\text{Ade}$ was in fact synthesised and that a heat-stable, dialysable substance was the actual acceptor of the isopentenyl group. Tests on various compounds related to adenine showed that adenine nucleotides such as 5'-AMP, ADP, ATP and 3', 5'-cyclic AMP, but not adenine or adenosine, could replace the supernatant of nondialysed, boiled S-100 in synthesis of $i^6\text{Ade}$ (data not shown). These results were confirmed in another kind of reaction using ^{14}C -labelled compounds as acceptors and unlabelled Δ^2 -isopentenylpyrophosphate as donor; addition of 5'-AMP, ADP, ATP or cyclic AMP led to formation of $i^6\text{Ade}$, while addition of Ade or Ado did not. An example is shown in Fig. 2. In this experiment, isopentenyladenosine ($i^6\text{Ado}$) was also produced. Of the adenine nucleotides tested, 5'-AMP seemed to be the direct acceptor of isopentenyl group, because addition of unlabelled 5'-AMP strongly inhibited the formation of $i^6\text{Ade}$ when ^{14}C -ADP, ^{14}C -ATP or ^{14}C -cyclic AMP was used, whereas addition of cold ADP, ATP or cAMP only slightly inhibited the synthesis of ^{14}C - $i^6\text{Ade}$ from ^{14}C -AMP (data not shown).

To confirm the identity of the direct substrate in synthesis of $i^6\text{Ade}$, S-100 was purified by gel filtration on a Sephacryl S-200 column (Fig. 3), and each fraction was assayed for formation of a radioactive product extracted with ethylacetate, using ^{14}C -AMP and unlabelled Δ^2 -isopentenylpyrophosphate as substrates. The activity appeared in a central fraction as a sharp peak. The radioactive products were found to be a mixture of ^{14}C - $i^6\text{Ade}$ and ^{14}C - $i^6\text{Ado}$. With this fraction as enzyme source, ^{14}C -cyclic AMP or ^{14}C -ATP was not utilised for the synthesis of $i^6\text{Ade}$ and $i^6\text{Ado}$, indicating that 5'-AMP is the direct acceptor of the isopentenyl group. It is very likely that the first reaction product is isopentenyl AMP ($i^6\text{AMP}$) and that this is converted to $i^6\text{Ado}$ and $i^6\text{Ade}$. To confirm this possibility, the peak fraction in Fig. 3 was further purified by phosphocellulose column chromatography. Fractions were assayed by analysing the total reaction products by thin-layer chromatography without previous treatment of the mixture with ethylacetate. As shown in Fig. 4, ^{32}P - $i^6\text{AMP}$ was in fact synthesised from ^{32}P -AMP. Radioactive $i^6\text{Ade}$ was also synthesised by fractions 18 to 20 using ^{14}C -AMP instead of ^{32}P -AMP without formation of ^{14}C - $i^6\text{Ade}$ or ^{14}C - $i^6\text{Ado}$ (data not shown). These results show that the first reaction product is $i^6\text{AMP}$. Because scarcely any $i^6\text{Ade}$ or $i^6\text{Ado}$ was detected, the enzymes which convert $i^6\text{AMP}$ to these products were thought to be separated from the enzyme synthesising $i^6\text{AMP}$.

It can be concluded from these studies that the overall pathway for $i^6\text{Ade}$ synthesis is as follows:

Further investigations are needed to determine whether $i^6\text{Ade}$ is formed directly from $i^6\text{AMP}$ or through $i^6\text{Ado}$. $i^6\text{AMP}$ was scarcely detected in the reaction mixture using a crude extract, due to its quick degradation to $i^6\text{Ade}$. This indicates that the cells contain exclusively $i^6\text{Ade}$, but not its nucleotide. In this respect it should be noted that cytokinin activity of $i^6\text{Ade}$ is almost 2 orders of magnitude higher than that of $i^6\text{Ado}$, $i^6\text{AMP}$ and cyclic $i^6\text{AMP}$, when the activity was determined by the tobacco assay⁸.

It is well known that cyclic AMP acts as a chemotactic factor causing aggregation of *D. discoideum* cells^{9,10}. 5'-AMP, which is the first substrate for $i^6\text{Ade}$ biosynthesis, is formed by hydrolysis of cyclic AMP by cyclic AMP phosphodiesterase, and that cyclic AMP, $i^6\text{Ade}$ and discadenine are all compounds related to adenine. Thus these compounds may be closely inter-

Fig. 4 Autoradiography of a thin-layer chromatogram of the products synthesised by the fractions obtained by phosphocellulose column chromatography. The peak fractions from Sephacryl S-200 (fractions 49–51) were pooled and applied to a phosphocellulose column (Whatman P11, 0.7×12 cm) which had previously been equilibrated with buffer B. Elution was carried out with a linear gradient of KCl (0–0.5 M; total volume of the gradient, 30 ml) and 1-ml fractions were collected. The reaction mixture contained 20 mM Tris-HCl pH 7.5, 5 mM magnesium acetate, 0.5 mM Δ^2 -isopentenylpyrophosphate 0.2 μ Ci of 32 P-5'-AMP (500 mCi mmol $^{-1}$) and 20 μ l of phosphocellulose column fraction in a final volume of 50 μ l. After incubation at 27 °C for 60 min, reaction mixture was cooled in ice and 5- μ l portions were spotted directly onto thin-layer plates coated with cellulose powder (20 \times 20 cm, Funakoshi). Material was developed using isobutyric acid–0.5 M NH_4OH (5:3, v/v). 32 P-5'-AMP was synthesised by the method of Symons⁶. Unlabelled i^6 AMP used as marker was synthesised by the method of Yoshikawa *et al.*⁷.

related, with important roles in regulation of the development of *D. discoideum*. In *D. discoideum*, i^6 Ade is an intermediate in discadenine biosynthesis, but it probably also has some important physiological activity itself, like cytokinin in higher plants.

We thank Dr T. Sasaki for helpful discussions.

X chromosome inactivation in diploid parthenogenetic mouse embryos

THE mechanism by which one X chromosome in normal cells of female mammals becomes inactive while the other, apparently identical, chromosome remains active is not known. In kangaroos the paternally derived X chromosome is preferentially inactivated in most tissues¹, and in mice and rats similar preferential inactivation of the paternal X chromosome occurs in the cells of the extraembryonic membranes^{2,3}. Paternal X inactivation in kangaroos led Cooper⁴ to postulate that passage of the X chromosome through male gametogenesis was an important factor in its inactivation. He⁴ and Brown and Chandra⁵ suggested that paternal X inactivation was a primitive form and that random X inactivation as seen in adult eutherian mammals had evolved from it. Brown and Chandra further suggested that passage of one chromosome set through male gametogenesis or fertilisation led to chromosomal imprinting. A locus concerned in the control of X chromosome activity was postulated to become inactive when imprinted, and one active copy of this gene could maintain the activity of one

X chromosome. In marsupials this gene was postulated to lie on the X chromosome itself, but on an autosome in eutherians. Thus, in eutherians the number of active X chromosomes in any animal should be equal to the number of maternally derived (and therefore non-imprinted) autosome sets. In this context it is interesting to study X inactivation in artificially formed parthenogenetic embryos, in which all chromosomes are of maternal origin. We report here that diploid parthenogenetic mouse embryos, at the late egg cylinder stage, showed a single late replicating chromosome, indicating that X inactivation had occurred normally. Because in the production of these embryos polar body formation had been suppressed, it seems that neither passage of chromosomes through male gametogenesis, nor fertilisation, nor probably the effects of peripheral egg cytoplasm are required for normal X inactivation in the mouse.

In the normal mouse embryo X chromosome inactivation is thought to occur at the late blastocyst stage⁶, and a late replicating X chromosome can be recognised at about the 5-d⁷ to 7-d stage⁸. Thus, studies of DNA replication in parthenogenetic embryos at the late egg cylinder stage should indicate whether normal X inactivation has occurred.

Experimental parthenogenetic mouse embryos have been produced by various means⁹, and Kaufman *et al.*¹⁰ have achieved development of a high proportion of diploid parthenogenotes to the egg cylinder stage or later. We have now studied DNA replication by ³H-thymidine labelling at the late egg cylinder stage in diploid parthenogenetic embryos produced by their method. Eggs were activated by culturing cumulus masses containing recently ovulated oocytes for 5–6 h in medium lacking calcium and magnesium salts. Then the cumulus cells were removed with hyaluronidase, and the successfully activated presumptive diploid eggs (which developed two pronuclei after suppression of second polar body formation or extrusion) were cultured for a further 90 h in normal embryo culture medium, by which time approximately 60% had reached the blastocyst stage. Blastocysts were then transferred to pseudopregnant recipient females, which had been mated to proven sterile vasectomised males 2.5 d earlier. Recipients were ovariectomised bilaterally at the time of transfer of blastocysts, and pregnancy was maintained by exogenous hormones, so that the time of implantation could be controlled. Implantation began about 24 h after the first of a series of oestradiol injections, which were started 6 d after blastocyst transfer. Females were killed after 4 d of injections when the embryos were expected to be at a stage equivalent to about day 7.5–8.5 of normal development. The embryos were dissected free from the decidua and embryonic membranes, and placed in Eagle's medium, supplemented with foetal calf serum (20%) at 37 °C.

In the mouse, because of its many segments of constitutive heterochromatin, the asynchronously replicating X chromosome is more readily detectable by its failure to take up ³H-thymidine early in the S period, than by its excess labelling at the end of S^{8,11}. We therefore attempted to study chromosome replication patterns early in S. Embryos were allowed to incorporate ³H-thymidine (final concentration 5 μ Ci ml⁻¹; specific activity 6 Ci mmol⁻¹) for 30 min at 37 °C, followed immediately by three washings with unsupplemented medium, and a chase of medium containing a 100-fold excess of unlabelled thymidine for 10 h. Colchicine, at a final concentration of 1 μ g ml⁻¹, was present during the final 2 h of the 10-h incubation. Air-dried slides were prepared according to a modification of the method of Wroblewska and Dyban¹² and autoradiographs were prepared.

Of six embryos studied four yielded scorable mitoses. Cells with 40 chromosomes were scored for uptake of label, and for presence or absence of a single large unlabelled chromosome, presumed to be an X chromosome. In all four embryos some cells showed a clear asynchronously replicating chromosome (Table 1). In all cells this was a large chromosome, of approximately the expected size of an X chromosome (Fig. 1). In most cases the asynchronous chromosome was unlabelled in an otherwise fully labelled cell (Fig. 1a, b), but in a few cells there was a single heavily labelled chromosome in a lightly labelled set (Fig. 1c). In addition some interphase cells showed an apparent X chromatin body (Fig. 1d).

The proportion of cells showing any label varied somewhat (from 17 to 42%) among the embryos, but the proportion of labelled cells with an asynchronous chromosome

Table 1 Cells with asynchronous presumed X chromosomes in diploid parthenogenetic mouse embryos

Embryo no.	Cells examined	Cells labelled (%)	Labelled cells with asynchronous chromosome (%)
1	107	39 (36)	25* (64)
2	87	27 (31)	15* (56)
3	46	8 (17)	5 (63)
4	12	5 (42)	4 (80)
Total	252	79 (31)	49 (62)

* A few cells (four in embryo 1 and two in embryo 2) showed a late replication pattern, that is a single heavily labelled chromosome in an otherwise lightly labelled cell.

showed reasonable consistency, with a mean of 62% (range 56–80%). The failure to detect an asynchronous chromosome in the remaining cells does not of course mean that one was lacking, because the cell cycle times may have been variable, with some cells being at mid-S, and therefore unsuitable for showing asynchronous replication, at the time of the ³H-thymidine pulse. The finding of a few cells with a replication pattern characteristic of late S emphasises this point.

Our interpretation is thus that the asynchronously replicating chromosome seen in all four embryos was a late replicating (and therefore inactive) X chromosome. Clearly differentiation of two X chromosomes within a cell can take place in embryonic development without the need for fertilisation or for passage of either chromosome, or indeed any autosome, through male gametogenesis.

A similar conclusion was reached by McCaw and Latt¹³ who found late replicating X chromosomes in human

Fig. 1 a–c, Autoradiographs of cells from diploid parthenogenetic mouse embryos. a, Single unlabelled chromosome in heavily labelled cell. b, Same cell after removal of silver grains. c, Single heavily labelled chromosome in otherwise lightly labelled cell (characteristic late-S replication pattern). d, Apparent X chromatin body in some interphase nuclei. Ilford Nuclear Research emulsion, gel form L4, was used for autoradiography. Slides were exposed for 3 weeks at room temperature, developed in Amidol developer, fixed and stained with Giemsa. Silver grains were removed by transferring slides through xylene and graded alcohols to potassium ferricyanide, sodium thiosulphate and distilled water.

ovarian teratomata, which arise by parthenogenetic growth of germ cells¹⁴, and by Linder and Power¹⁴ on the basis of X-linked gene expression in such teratomata. Our work strengthens the finding by dealing with embryos which were undergoing fairly normal development (up to the relevant stage), rather than teratomata in which the genetic programming might be in some way disturbed. Thus, these results are inconsistent with the expectation from Brown and Chandra's hypothesis that the number of active X chromosomes in any cell should be equal to the number of maternally derived autosome sets. In their development¹⁵ of the original hypothesis they reconciled the X inactivation seen in certain human ovarian teratomata and a diploid/triploid mosaic by postulating that chromosomal imprinting occurred not during male gametogenesis but during passage of chromosomes through the egg cytoplasm. Normally this would occur at fertilisation, but in the cases mentioned the effect was produced by re-entry of the polar body. Our embryos were inconsistent even with this, because the parthenogenetic activation was produced in combination with suppression of polar body formation. Further evidence against Chandra and Brown's ideas has come from human triploid foetuses one of which had two active X chromosomes although only a single autosome set from the mother¹⁶ and another which had a single active X chromosome but two haploid sets from the mother¹⁷.

Thus we conclude that in eutherian mammals there is no evidence that chromosomal imprinting is required for the initiation of X-chromosome inactivation. This does not, of course, exclude the possibility of imprinting in normal embryogenesis. Preferential inactivation of the paternally derived X chromosome (manifested by late replication as detected by acridine orange fluorescence after BUdR incorporation) has been found in the extraembryonic membranes but not the foetus itself of both the mouse and the rat^{2,3}. Thus it seems probable that in eutherians, as in marsupials, imprinting of the paternally derived X chromosome does occur, but that the cells of the embryo proper escape from imprinting before X inactivation¹⁸. One might expect therefore that in parthenogenetic embryos X inactivation would be in some way abnormal in the extraembryonic membranes. Further work is necessary to test this point.

M.H.K. thanks Mrs S. C. Barton and Dr M. A. H. Surani for help. The work was supported by a grant from the Ford Foundation.

Localisation and stimulation of prostacyclin production in vascular cells

PROSTACYCLIN (PGI₂) was reported by Vane and co-workers as a novel short-lived metabolite of prostaglandin endoperoxides (PGG₂ and PGH₂) which inhibited platelet aggregation¹. Subsequent studies have demonstrated that PGI₂ is the most potent inhibitor of platelet aggregation so far described, acting by stimulating platelet adenylate cyclase^{2–4}. PGI₂ is produced by isolated blood vessel segments⁵ and is therefore likely to be of great importance in the maintenance of vascular homeostasis. The cellular localisation and regulation of PGI₂ synthesis have not previously been established, although it has been proposed that the main source of PGI₂ is through pro-aggregatory prostaglandin endoperoxides released from platelets being enzymatically converted to PGI₂ by vascular endothelial cells^{5,6}. We show here that pig aortic endothelial cells, but not aortic smooth muscle cells or fibroblasts, synthesise PGI₂. This production of PGI₂ is stimulated by incubating endothelial cells with PGG₂ or with its precursor, arachidonic acid. Furthermore, PGI₂ synthesis is powerfully stimulated by cell-free plasma.

Pig aortic endothelial cells, aortic medial smooth muscle cells, and aortic adventitial fibroblasts, were isolated and grown in homogeneous monolayer cultures according to previously described methods^{7,8}. For experiments cells were detached (0.1% trypsin + 0.025% EDTA; 37 °C; 2 min) and suspended in serum-free HEPES-buffered Dulbecco's medium. Subsamples were resuspended in small volumes of calcium and magnesium-free phosphate-buffered saline (PBS) immediately before use. Platelet-rich plasma (PRP) was prepared by differential centrifugation of whole blood, anticoagulated with citrate or heparin; platelet aggregation was measured photometrically⁹ in 0.1 ml samples of human PRP¹⁰. All incubations were at 37 °C. Arachidonic acid (Sigma, Grade I) was prepared as the sodium salt, stored under nitrogen at –20 °C, and used within 2 weeks. Arachidonic acid was converted enzymatically¹¹ to 15-hydroperoxyarachidonic acid (15HPAA), a specific inhibitor of PGI₂ synthesis¹², and used immediately.

In previous studies of the effects of freshly isolated endothelium on platelets¹³ (and in preliminary studies with cultured vascular cells¹⁴) observations were first made by mixing cells with PRP, and we therefore performed similar experiments. Suspensions of 1.6–3.3 × 10⁴ endothelial cells, mixed with 0.1 ml human PRP, inhibited (with similar potency) platelet aggregation induced by ADP, collagen, vasopressin or the PGH₂ analogue (15S)-hydroxy-9α, 11α-epoxymethanoprostanoic acid (15E-dienoic acid (U44069)). This inhibitory effect was reduced by pre-incubating the endothelial cells (5 min) with 1 mM aspirin, an inhibitor of the cyclo-oxygenase component of the prostaglandin biosynthetic pathway¹⁵, and abolished by pre-incubating the cells with 1 mM 15HPAA. It was also reduced if PRP was pre-incubated (2 min) with 100 μM 2',5'-dideoxyadenosine (DDA), an inhibitor of platelet adenylate cyclase¹⁶. Thus, the inhibitory factor produced by mixing PRP with endothelial cells has properties characteristic of PGI₂.

In contrast, suspensions of either smooth muscle cells or fibroblasts, when mixed with PRP, induced platelet aggregation directly; the aggregation responses were similar to those produced by purified collagen, and were inhibited either by pre-incubating the vascular cells with collagenase or by pre-treating the PRP with aspirin or with a stimulant of adenylate cyclase (see Fig. 1). These results indicate that platelet aggregation was induced by cell-associated collagens known to be synthesised by these cells in culture^{17,18}. Because smooth muscle cells and fibroblasts aggregated platelets we could not, by direct mixing experiments, exclude the possibility that these cells might produce PGI₂.

Vascular tissue incubated with buffer alone, or with arachidonic acid or PGG₂, has been shown to produce sufficient PGI₂ for subsamples of the supernatant to inhibit platelet aggregation¹⁹.

Fig. 1 Platelet aggregation induced by aortic smooth muscle cells or fibroblasts. *a*, Smooth muscle cells (5.2×10^4) in PBS were centrifuged (15,000g, 10 s) in an aggregometer cuvette and the supernatant was discarded. Human citrated PRP, 0.1 ml, was added, the mixture stirred at 37 °C and aggregation recorded. 1, Control response. 2, Cells pretreated with 0.2% collagenase in Dulbecco's medium (37 °C; 15 min). 3, PRP pretreated with 10 μM PGD₂ (37 °C; 2 min). *b*, Fibroblasts (6.6×10^3) prepared as above. 1, Control response. 2, Cells pretreated with collagenase. 3, PRP pretreated with 1 mM aspirin (37 °C; 5 min).

We therefore adopted this approach to characterise in more detail the localisation and regulation of PGI₂ production by vascular cells. To test for spontaneous production of PGI₂, cells were incubated in PBS for 2 min and subsamples of the supernatant added to PRP. To test for stimulation of PGI₂ production, cells were pre-incubated with 1 mM arachidonic acid or 0.2 μM PGG₂, washed in PBS alone for 2 min, and subsamples of these supernatants were tested as before. We have so far investigated PGI₂ production in aortic endothelial cell cultures, tested at between 2 and 17 passages in culture, derived from nine animals. Cells (5×10^3 – 10^5) cultured from five animals produced detectable levels of PGI₂ after incubation in PBS alone for 2 min, whereas incubations of up to 10^5 cells from the other four animals did not. We have also found PGI₂ production by endothelial cells cultured from the pig post-caval vein.

The inhibitor was characterised as PGI₂ by the following criteria: its activity was labile (half life ~ 5 min at 37 °C); its production was inhibited by pre-incubating endothelial cells with 15HPAA, aspirin, indomethacin, or mepacrine (an agent that blocks prostaglandin production in platelets by inhibiting

the plasmalemmal phospholipase A₂ responsible for endogenous arachidonic acid release²⁰); its effect was potentiated by pre-treating PRP with papaverine (a phosphodiesterase inhibitor) and inhibited by pretreating PRP with DDA (see Fig. 2). The inhibitor was active against primary aggregation induced by ADP, vasopressin and U44069; the effects of the latter two agonists are independent of ADP²¹, suggesting that in these conditions little, or none, of the inhibition is due to ADPase activity known to be present in aortic tissue^{22,23}. Secondary aggregation responses induced by ADP, U44069, collagen and arachidonic acid were also inhibited.

Cells from all animals tested produced easily detectable amounts of PGI₂ when stimulated with arachidonic acid or PGG₂. Although one culture, when retested after 16 passages, had lost the ability to produce detectable quantities of PGI₂, whether cells were stimulated with PGG₂ or added directly to PRP, other cells still produced PGI₂ after at least 17 passages. We have been unable to detect any enhanced PGI₂ production by pre-incubating endothelial cells (5 min) with 10–100 μg ml⁻¹ bradykinin or 10 μg ml⁻¹ angiotensin II, which stimulate production of prostaglandins E and F by cultured endothelium^{24,25}, and we have not observed any stimulation of PGI₂ production by thrombin at concentrations up to 25 U ml⁻¹. We have never observed the production of any inhibitor of platelet aggregation by smooth muscle cells or fibroblasts, even after stimulation with arachidonic acid or PGG₂.

Our results demonstrate that vascular endothelium, but not smooth muscle cells or fibroblasts, can synthesise PGI₂; this confirms and extends the preliminary observations made by Harker *et al.*¹⁴. Endothelial cultures from all animals tested, including those cells which failed to produce detectable PGI₂ on incubation with PBS alone, did inhibit platelet aggregation by producing PGI₂ when directly mixed with PRP. This implies that a factor (or factors) in PRP stimulate(s) PGI₂ production. One such factor could be a prostaglandin endoperoxide released from platelets; however, 5 min pre-incubation of PRP with 1 mM aspirin or 100 μM indomethacin had no effect on the inhibition by endothelial cells of primary platelet aggregation, which indicates that platelets are not necessary for the supply of precursor prostaglandin endoperoxides to endothelial cells for PGI₂ production. To investigate the possibility that other platelet-derived products might be responsible for stimulating PGI₂ production, we tested the effects on vascular cells of cell-free plasma, prepared in conditions which minimised secretion of platelet constituents. Incubation of 3.3×10^4 endothelial cells with 0.1 ml of cell-free plasma for 2 min, then centrifuging and resuspending in PBS alone for 2 min, resulted in the production of levels of PGI₂ (characterised by the criteria used above) detectable in as little as 2 μl of supernatant, and the amount of PGI₂ synthesised was directly related to the volume of cell-free plasma used as a stimulus (see Fig. 3). We have been able to stimulate PGI₂ production using plasma diluted as much as 50-fold with PBS. Smooth muscle cells (up to 3.3×10^5) did not produce PGI₂ on incubation with plasma. The stimulation of endothelial PGI₂ production was evident using human plasma prepared with citrate, heparin or EDTA, or human serum; and also with pig or rat plasma. PGI₂ production was stimulated equipotently by PRP or cell-free plasma, further indicating that in normal conditions platelet prostaglandin endoperoxides do not contribute significantly to endothelial PGI₂ production. The factor in cell-free plasma was heat labile (56 °C; 30 min), non-dialysable, and was still present after freezing of plasma.

The stimulation of PGI₂ production obtained using human cell-free plasma (which contains about 10 μM arachidonic acid²⁶) was comparable to that obtained by adding 500 μM arachidonic acid in PBS, even in the absence of albumin. It is therefore unlikely that PGI₂ synthesis is stimulated by precursor arachidonic acid carried on circulating plasma albumin. A more probable explanation is that the plasma factor stimulates PGI₂ production in a manner analogous to that by which RCS-RF (rabbit aorta contracting substance-releasing factor) stimulates

Fig. 2 Characterisation of PGI₂ production by endothelial cells. Suspensions of cells in PBS were incubated for 2 min at 37 °C centrifuged (15,000g, 10 s) and subsamples of the supernatant (50 μl, or 50 μl of PBS alone for controls) added to 50 μl human citrated PRP. After mixing for 1 min at 37 °C, aggregation responses to 1 μM ADP were measured. *a*, 1, Control; 2, supernatant from 1.6×10^4 cells; 3, supernatant from 6.6×10^4 cells. *b*, 1, Supernatant from 6.6×10^3 cells; 2, control, but PRP pre-incubated (37 °C, 2 min) with 20 μM papaverine; 3, as 1 but PRP pre-incubated with papaverine. *c*, 1, Supernatant from 3.3×10^4 cells; 2–6, as 1, but: 2, PRP pre-incubated (37 °C, 2 min) with 100 μM DDA; 3, cells pre-incubated (37 °C, 5 min) with 1 mM 15HPAA in PBS (before incubating in PBS alone); 4, cells pre-incubated (37 °C, 5 min) with 1 mM aspirin; 5, cells pre-incubated (37 °C, 5 min) with 100 μM indomethacin; 6, cells pre-incubated (37 °C, 5 min) with 50 μM mepacrine.

Fig. 3 Stimulation of endothelial cell PGI_2 production by cell-free plasma. Suspensions of 3.3×10^4 cells were pre-incubated in 0.1 ml human citrated cell-free plasma, or plasma diluted with PBS, for 2 min (37°C); centrifuged ($15,000g$, 10s), re-suspended in 0.1 ml PBS and incubated for a further 2 min. After centrifuging, subsamples of the supernatant were added to 50 μl of human citrated PRP, with sufficient PBS to give a final volume of 0.1 ml. After mixing for 1 min at 37°C , aggregation responses to 1 μM ADP were measured. *a*, Cells treated with undiluted plasma. 1, Control, 50 μl PBS alone; 2, 2 μl supernatant; 3, 10 μl supernatant; 4, 25 μl supernatant. *b*, 1, control; 2, 50 μl supernatant, but cells pretreated with 0.1 ml plasma diluted 1:10 with PBS; 3, as (2) but plasma diluted 1:1; 4, as (2) but plasma undiluted.

thromboxane A_2 production in lung tissue²⁷. This suggestion is strengthened by our finding that 5 min pre-incubation of endothelial cells with $4 \mu\text{g ml}^{-1}$ betamethasone, which antagonises RCS-RF activity²⁷, blocked PGI_2 synthesis. The lack of detectable effects of bradykinin and angiotensin II on PGI_2 synthesis, in contrast to their stimulation of endothelial PGE and PGF production^{24,25}, suggests that the plasma factor may selectively stimulate PGI_2 production.

The previous proposal that vascular PGI_2 production may be an important regulatory mechanism in haemostasis and thrombosis^{1,5} is reinforced by our findings that PGI_2 synthesis is localised in endothelial cells and that cell-free plasma alone stimulates PGI_2 production.

We thank the MRC for financial support. DDA was donated by Dr R. J. Haslam, PGG_2 by Dr E. W. Salzman, and all other prostaglandins by Dr J. E. Pike (Upjohn).

Note added in proof: Since this manuscript was submitted, three directly relevant papers have been published. Weksler *et al.*²⁸ present chemical evidence for prostacyclin production by cultured human and bovine aortic endothelium, but not by human fibroblasts. Baenziger *et al.*²⁹ report the synthesis of prostacyclin by cultured human aortic smooth muscle cells and fibroblasts. We therefore carried out further experiments, and by using $>3.3 \times 10^5$ smooth muscle cells, have found some strains to produce a transferable inhibitor of platelet aggregation. To produce comparable inhibition, however, required approximately $100 \times$ smooth muscle cells as endothelial cells. Moncada *et al.*³⁰ have shown that the conversion of PGH_2 to prostacyclin by rabbit aorta is at least tenfold greater (on a wet weight basis) in the intimal layer than in the media or adventitia.

Sister chromatid exchange as an indicator of mutagenesis

SISTER chromatid exchange (SCE), that is, the reciprocal interchange of DNA between chromatids, is easily visualised in metaphase chromosomes^{1,2} and has been applied to study chromosome structure^{3,4}, chromosome damage⁵, and instability and DNA repair deficiency syndromes^{6–9}. Since SCEs can be induced by subtoxic doses of carcinogens and mutagens^{5,10–13}, their analysis offers the possibility of a rapid, sensitive and quantitative assay for genetic damage. We have begun to examine the relation between SCEs and mutations in Chinese hamster ovary (CHO) cells by quantifying the induction of SCEs in parallel with the induction of mutations producing 8-azaguanine resistance, that is, mutations predominately at the hypoxanthine phosphoribosyltransferase, *hprt*, locus. Since the conversion of a chemically induced DNA lesion to a SCE or mutation may depend on the nature of that lesion, we tested four chemicals that differ in their interaction with DNA—ethyl methanesulphonate (EMS; O^6 : N^7 guanyl alkylation ratio¹⁴ of 0.03), *N*-ethyl-*N*-nitrosourea (ENU; O^6 : N^7 guanyl alkylation ratio¹⁵ of about 0.35), the crosslinking agent mitomycin C (MMC)¹⁶ and the intercalator proflavine sulphate (PRO)¹⁷. Our results indicate a linear relation between induced SCEs and mutations. The relative efficiency, however, is different for each chemical.

As shown in Fig. 1, EMS, ENU and MMC produced a linear increase in both induced SCEs and mutations as a function of dose. All six regression lines for these chemicals had slopes significantly different from zero. Proflavine did not produce a significant increase ($P>0.05$) in either SCEs or mutations over the dose range tested, even though the highest dose (1.6 μM) reduced cell survival to approximately 60%. (Note the range of the ordinate in Fig. 1d compared to the other chemicals). For comparison with the other chemicals, however, we have treated these data as an indication of a positive response in both assays. Each of the four

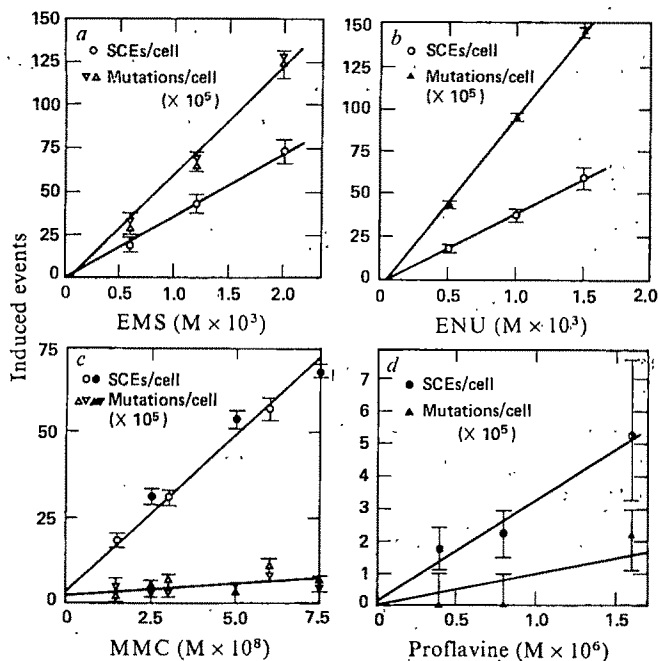

Fig. 1 The induction of SCEs and mutations as a function of dose for: a, EMS; b, ENU; c, MMC; and d, PRO. Circles represent SCEs per cell; triangles represent mutations per cell $\times 10^5$. A suspension-adapted clone of the CHO line designated SC1 was cultured in 200-ml spinner flasks in α minimum essential medium (MEM) with 10% foetal calf serum. With the cells growing exponentially at a density of $1.3 \times 10^5 \text{ ml}^{-1}$, 5-bromodeoxyuridine (BrdU), at a final concentration of $10 \mu\text{M}$, and the test chemicals were added to each culture. Control cultures contained only BrdU. After 18 h exposure (approximately 1.5 generations), the cells were collected by centrifugation, then rinsed once and resuspended in fresh medium. At each dose the culture was divided into two portions. The first fraction of each treated culture was subdivided into four identical 20-ml roller-tube cultures containing $10 \mu\text{M}$ BrdU, which were used to prepare chromosomes for SCE analysis. To ensure collection of the majority of second-division cells, sequential cell collection of the roller tubes was performed at 4-h intervals from 18 to 34 h. Colcemid (10^{-7} M final concentration) was added 4 h before cell collection. SCEs were differentiated by the FPG technique² and 25 cells were scored at each dose. For each 4-h collection interval an average SCE frequency for each dose was calculated by weighting the SCE frequency by the mitotic index of second-division cells in that interval. All operations before cell fixation or plating for mutations were performed in the dark or under a safelight. The second fraction of each treated culture was grown further, with low-ratio dilutions, in the absence of BrdU for mutation expression and selection. On days 4 and 5 (EMS and MMC) or day 4 (ENU and PRO) after removal of the chemicals these cultures were rinsed with serum-free medium and plated into regular medium (α -MEM + 10% dialysed foetal calf serum) for plating efficiency determinations, and into the same medium containing $15 \mu\text{g ml}^{-1}$ 8-azaguanine for selection of drug-resistant mutant colonies. The use of dialysed serum produced a reproducible assay in which all colonies isolated and tested were more drug-resistant than wild type¹⁸. The frequency of mutant colonies detected was proportional to cell inoculum in the conditions used, showing that cell density was not a complicating factor. Ten replicate 100-mm Petri dishes were seeded with 4×10^6 cells each and stained after 14 d of incubation. Plating efficiencies were determined by inoculating 300 cells per dish (five replicates) and staining after 8 d. Mutation expression was found to be maximal by four generations after exposure. The average mutation frequency in the presence of BrdU alone (controls) was $5.18 \pm 0.65 \times 10^{-5}$ (\pm s.e.m.) mutants per survivor. There was no apparent increase in the spontaneous mutation frequency from the presence of BrdU. The frequency of SCE in the controls was 7.03 ± 0.24 per cell averaged over five experiments. Control values were subtracted to obtain induced frequencies. The data were fit using a least squares linear regression with 0,0 as a data point. The open and closed triangles for MMC in (c) indicate two independent experiments. The two triangles for each dose in (a) and (c) represent day 4 and 5 platings; data were pooled for the regression analysis. Standard errors of the mean for the SCE data represent the sample time variation for each dose. Standard errors for the mutation frequencies represent Poisson counting error.

chemicals induced both SCEs and mutations over the same concentration range, suggesting a similarity in the sensitivity of the two assays. The slope of each regression line from Fig. 1 was used as a measure of the induction efficiency for SCEs or mutations, as shown in Table 1. On a molarity basis, both SCEs and mutations increase over four orders of magnitude as follows: $\text{EMS} < \text{ENU} < \text{PRO} < \text{MMC}$.

In Fig. 2 the frequency of induced SCEs per cell is compared with the frequency of induced mutations. The data show a linear relation between SCEs and mutations, but the ratio of induced SCEs to induced mutations (regression line slope) is different for each chemical (Table 1). Of the four chemicals, ENU is the least efficient inducer of SCEs compared with mutations (lowest ratio) while MMC is most efficient (highest ratio); these compounds differ by a factor of 15. Thus, it is clear that there is a positive, linear correlation between SCEs and mutations, but the relative efficiency of SCE and mutation induction varies with the compound. The type of lesion produced by each chemical and the nature of its repair probably determine the relative frequency of induced SCEs and mutations. Therefore, in order for SCEs to be a quantitative predictor of mutation induction, calibration curves similar to those in Fig. 2 may have to be derived for each agent.

Obviously many more chemicals must be compared before any general conclusions can be drawn concerning the relation of SCEs and mutations. Also, other genetic markers must be tested since azaguanine resistance may not have typical mutagen sensitivity for each chemical. If we do assume that this marker yields a representative mutation rate and that the ratio of SCEs to mutations (Table 1) is similar in human cells, then for the approximately 50,000 structural genes in man¹⁹, the above data suggest that for every SCE per cell: EMS produces 0.85 mutations per cell; ENU produces 1.2 mutations; PRO produces 0.28 mutations; and MMC produces 0.08 mutations. The use of this rapid cytological SCE analysis as a quantitative indicator of mutagenesis seems feasible but must be approached with caution since each chemical or class of compounds may respond differently. The SCE:mutation ratio may also differ with species, tissue type, dose rate, or other factors, making it necessary to establish the relationship for the exposure condition of interest. If an SCE:mutation ratio obtained *in vitro* can be extrapolated to cells *in vivo*, it will then be possible to predict mutation rates in man from SCE

Fig. 2 The relationship between induced SCEs and induced mutations. Each set of data was fitted by a least squares linear regression with 0,0 as a data point. For MMC, the two sets of solid triangles represent separate dose responses performed on different days; the two sets were combined to generate a single regression line.

Table 1 Efficiency of induction of SCEs and mutation to azaguanine-resistance

Chemical	SCE per cell per mol per l		mutations per cell per mol per l		SCE per mutation	
	Absolute* ($\times 10^{-6}$)	Relative	Absolute* ($\times 1$)	Relative	Absolute† ($\times 10^{-4}$)	Relative
EMS	0.037	1.0	0.62	1.0	5.9	1.0
ENU	0.040	1.1	0.97	1.56	4.1	0.70
PRO	3.2	86	14.1	22.7	18	3
MMC	918	2.5×10^4	914	1.5×10^3	60	10

*Absolute efficiency is the slope of each dose response regression line in Fig. 1.

†Absolute ratio taken from slope of the regression lines in Fig. 2.

Eosinophil chemotactic factor release from neutrophils by *Nippostrongylus brasiliensis* larvae

INFESTATIONS with metazoan parasites are the most efficient stimulus known for the induction of eosinophilia, and eosinophils have been shown to have an essential role in the elimination of worms^{1,2}. Eosinophil chemotactic factors have been derived from lymphocytes³⁻⁵, mast cells⁶ and the complement system⁷. We reported recently the *in vitro* release of a low molecular weight eosinophil chemotactic factor, ECF, from human neutrophils (PMN) during phagocytosis of zymosan⁸. The evidence presented here shows that neutrophils, after incubation with larvae of *Nippostrongylus brasiliensis* (N.B.), can also generate this same factor which selectively attracts eosinophils *in vitro*. As neutrophils are the first cells to accumulate at tissue sites where parasites are located⁹⁻¹¹, the attraction of eosinophils may present an early line of defence against the invading organism.

N. brasiliensis-infested Wistar rats^{12,13} were used as a model system as it is difficult to obtain sufficient numbers of organisms from infected humans. Larvae were obtained from the faeces of infested Wistar rats, washed twice in a Tris-albumin buffer containing calcium and magnesium¹⁴, and incubated with 1×10^7 purified human PMN in a total of 1 ml at 37 °C for the time indicated. PMN were separated from other peripheral leukocytes by Ficoll-Hypaque¹⁵ flotation, followed by dextran sedimentation to eliminate erythrocytes. Cells and larvae were removed by rapid centrifugation in the cold and the supernatants analysed for eosinophil chemotactic activity using the method described previously¹⁴. Results are expressed as the

number of eosinophils that have migrated completely through nitrocellulose filters (Sartorius) in five 10×40 microscopic fields. Human and guinea pig eosinophils used in these studies gave comparable results. Controls with buffer alone were always negative. This assay of chemotaxis does not measure the weak eosinophil chemotactic activity induced by very low histamine concentration¹⁴.

Table 1 shows the release of ECF with varying numbers of larvae after a 20-min incubation. Neither larvae nor cells alone induced eosinophil migration, but the mixture of both caused a dose-dependent release of eosinophil chemotactic activity. Similar results were obtained with normal human PMN, with normal rat peritoneal cells or with cells from rats infected with larvae 10 days earlier. The slight increase in histamine release (Table 1) was not detectable in other experiments, indicating that the PMN and not the mast cells were the source of the ECF. Similarly, histamine levels were not raised in the PMN supernatants, excluding the rather unlikely possibility of release of ECF from unsensitized basophils. Chromatography of either active cell supernatants on a Sephadex G-25 column showed that, in each case, the eosinophil chemotactic activity was eluted in the same fractions as the ECF obtained from basophils by anti-IgE (ref. 14) and from PMN on exposure to zymosan (molecular weight about 500) (ref. 16). The differently induced ECF preparations did not differ in their biological behaviour such as the preferential attraction of eosinophils¹⁶.

The time course of ECF-release from PMN was also studied (Table 2). After a lag period of 5 min, there was rapid release of the mediator for up to 20 min and then a gradual decline. A very similar curve can be obtained during ECF release from PMN with zymosan¹⁶. The decreasing activity after extended incubation has been shown to be due to an inactivator released together with ECF from PMN¹⁷. The lysosomal enzyme β -glucuronidase (measured by the method of Brittinger¹⁸) was released in a time dependent fashion with no decline in release rate at later time intervals.

Opsonisation of the larvae enhanced release of both ECF and β -glucuronidase from the cells. The totally passive role of the larvae in these processes was underlined by the fact that imotile parasites which had been stored in the frozen state for several weeks were just as efficient in stimulating the cells as

Table 1 Release of ECF and histamine from human PMN and rat peritoneal cells

Larvae (ml ⁻¹)	No. cells Eos/5 HPF	PMN 1×10^7 /ml		Rat peritoneal cells 1×10^7 /ml	
		Eos/5 HPF	% Histamine	Eos/5 HPF	% Histamine
0	0±0	0-0	1.0	0±0	2.0
8	0±0	0±0	1.0	15±2	3.0
80	0±0	32±4	0.5	41±4	5.0
800	0±0	109±7	1.0	279±12	6.0

ECF release was measured after 20 min incubation at 37 °C. Eos/5 HPF, eosinophils that have migrated through the filter in five high-power fields. Human PMN, 3% eosinophils, 6% lymphocytes, 0.2% basophils, 91% neutrophils. Rat peritoneal cells, 5% mast cells, 13% eosinophils, 7% neutrophils, 75% lymphocytes and macrophages.

Table 2 Release of ECF (Eos/5 HPF) and β -glucuronidase¹⁸ from 1×10^7 purified human PMN (> 90% neutrophils) incubated with 80 larvae in 1 ml buffer

Time (min)	ECF (Eos/5 HPF)	β -Glucuronidase (A_{540})
0	0 \pm 0	0.017
5	0 \pm 0	0.025
10	30 \pm 3	0.067
15	38 \pm 4	0.077
20	41 \pm 3	0.078
30	24 \pm 2	0.078
60	20 \pm 2	0.099

ECF and β -glucuronidase release was measured after incubation at 37 °C for the times shown.

fresh larvae.

The interaction of larvae and neutrophils was followed under the light microscope. During the first 5 min the larvae were seen to be moving about actively, and only an occasional cell was seen attached to them. By 10 min, the PMN had formed larger clumps which were partly trapping the larvae and the larvae were beating about actively with their free ends, apparently trying to free themselves from the cells. By 20 min and later, most larvae were completely encased and immobilised by the cells. At times, five or six larvae were enclosed by one cell clump. Very few larvae were completely unaffected by the process of entrapment.

In the tissue the interaction between invading organism and the PMN probably occurs only in a restricted fashion. But, since neutrophils are the most numerous scavengers of the body and since they do not have to be sensitised to function, they must be considered the first line of defence against parasites. Within a brief time, they then secrete a substance that attracts eosinophils to the site. Compared to neutrophils, these cells contain larger amounts of certain enzymes (histaminase¹⁹, arylsulphatase²⁰, and myeloperoxidase²¹) and of basic proteins²² which may enable them to modulate the local inflammatory event in a way more favourable to the host.

It is important to remember that the release of ECF from the PMN is a very specific process with regard to the stimulus—phagocytosis of certain bacteria, has no such effect (data not shown). In addition, inhibitory factors in cells¹⁷ and tissues²³ may modulate the influx of eosinophils to inflammatory sites, and the final outcome of the neutrophil-associated inflammatory process may depend on the complex interaction of several factors.

In the light of these results, the induction of eosinophilia during parasitic infestations may be viewed as follows. First, PMN accumulate close to the parasite and, during the process of phagocytosis, release ECF which selectively attracts eosinophils and also some neutrophils. Local activation of complement and production of the neutrophil and eosinophil chemotactic fragment C5a (ref. 7), will also play a part early on in sustaining the influx of both cell types. This latter line of defence may be continuously active during the subsequent course, especially when circulating immune complexes²⁴ become available as an additional means of complement activation. Finally, lymphocyte- and mast cell-dependent mechanisms of induction of eosinotaxis are activated after sensitisation and production of specific IgE has occurred^{25,26}. It may well be that the response produced at this time is more effective in evoking and sustaining eosinophilia and in eliminating the invading organism. But the mechanisms induced at earlier times may serve to abort very mild infestations and/or to set the stage for a better immune response and a favourable outcome for the host.

Novel type of murine B-cell lymphoma

ALTHOUGH several murine T-cell lymphomas have been well characterised (reviewed in ref. 1), only a single group of murine B-cell lymphomas, the Abelson lymphomas, has been described². The Abelson lymphoma arose in a steroid-treated BALB/cCr mouse inoculated with Moloney leukaemia virus², expresses surface immunoglobulin^{3–4} and can be transmitted by an infectious murine leukaemia virus². We report here a new IgM-bearing B-cell lymphoma distinct from the Abelson lymphoma in its induction, pathogenesis and antigenic characteristics and which has many features in common with the widely studied guinea pig L₂C lymphoma^{5–6}.

The phenomenon reported here was observed during the selection of a new strain of mice—B10-H-2^a H-4^bp/Wts⁷. This 'double congenic' strain differs from the background strain C57BL/10 (H-2^b, H-4^a) at two segments of its genome; one surrounding the H-2 locus and another surrounding the H-4 locus. When B10-H-2^a H-4^bp/Wts mice were immunised with sheep erythrocytes and their spleen cells or sera were transferred to syngeneic or F₁ hosts (protocol previously described⁸), a lymphomatous disease resulted. Symptoms suggesting a lymphomatous disease occurred in more than 50% of the cell and serum recipients within 150 d of transfer. Strains congenic to B10-H-2^a H-4^bp/Wts at the H-4 (B10.A; H-2^a H-4^a) and H-2 (B10.129(21M); H-2^b, H-4^b) loci did not develop lymphoma when treated in the same manner.

The disease is characterised by hypersplenomegaly, lymph node enlargement and whitish nodes in the liver. The primary disease process does not seem to involve the thymus or bone marrow and the serum from tumour-bearing animals does not seem abnormal on electrophoresis. Several of these primary tumour-bearing animals have been observed and one B10-H-2^a H-4^bp/Wts tumour was selected for transplantation and characterisation.

The cell surface antigens expressed by the lymphoma cells are presented in Tables 1 and 2. When these transplanted ascites tumour cells were assayed for surface immunoglobulin with a polyvalent rabbit anti-mouse immunoglobulin, more than 80% of them were consistently found to be positive for Ig by indirect immunofluorescence (Table 1). Studies with heavy-chain-specific reagents demonstrated that most if not all of these Ig+ cells specifically expressed IgM, and not IgA or IgG. Qualitatively, the large lymphoblast-like tumour cells demonstrated very bright diffuse fluorescence indicating a high

surface concentration of IgM. Attempts to kill the lymphoma cells with rabbit anti-mouse immunoglobulin and complement were unsuccessful; yet, this antiserum induces strong agglutination of tumour cells (unpublished observation).

That this murine lymphoma does not bear thymus cell antigens is conclusively demonstrated by the results presented in Table 2. Although the rabbit anti-mouse brain antiserum used to detect mouse T cells reacts with most of the tumour cells by indirect immunofluorescence, this phenomenon does not depend on a T-cell-specific antigen. Absorption of the rabbit anti-mouse brain antiserum with tumour cells does not remove the antibodies directed at normal mouse thymocytes. Additionally, absorption of the rabbit anti-mouse brain with thymocytes does not remove its reactivity with tumour cells; yet, does remove the anti-T-cell antibodies. The nature of this cross-reactive antigen is being investigated. Negative results from dye exclusion cytotoxicity assays with a specific anti-Thy 1.2 antiserum, as well as the rabbit anti-mouse brain, further substantiate that this tumour is not of thymic origin (Table 2).

Our preliminary evidence clearly distinguishes the B10-H-2^a H-4^bp/Wts B lymphoma from the only other characterised group of murine B-cell lymphomas, the Abelson lymphomas. There are several important differences. First, induction: the lymphoma reported here is induced in recipients of sera or cells from immunologically stimulated B10-H-2^a H-4^bp/Wts donors. Cell transfers from other congenic strains do not induce tumorigenesis. Conversely, Abelson lymphoma was induced in a BALB/cCr mouse treated with an immunosuppressant and inoculated with Moloney leukaemia virus². Second, pathogenesis: the B10-H-2^a H-4^bp/Wts lymphoma mainly involves the peripheral lymphoid organs, in particular the spleen. This contrasts with the Abelson lymphoma which primarily involves the bone marrow cells and the meninges¹¹. Third, antigenic characteristics: although both Abelson B-cell lymphoma and the lymphoma reported here bear surface immunoglobulin, at least their quantity of expression differs. Sklar *et al.*³ have reported that cells infected with Abelson virus express surface immunoglobulin; yet, surface immunoglobulin can only be detected by very sensitive detection methods⁴ and only on a minor percentage of these tumour cells³. This is not the case with the B10-H-2^a H-4^bp/Wts lymphoma. Ninety per cent of these cells show very bright fluorescence with an anti- μ specific antiserum (Table 1). These lymphoid cells are probably monoclonal, and the nature of the idiotypic determinants of this surface IgM is being investigated.

Table 1 Expression of surface immunoglobulin by B10-H-2^a H-4^bp/Wts lymphoma cells

Primary antisera	% Immunofluorescence		
	Spleen	Thymus	Tumour
Rabbit anti-mouse Ig	35	<1	83
Goat anti- μ *	45	<1	90
Goat anti- α *	<1	<1	<1
Goat anti- γ *	10	<1	<1

Indirect immunofluorescence was performed as follows. 5×10^6 cells were suspended in 0.1 ml of the appropriate primary antiserum and incubated for 30 min at 4 °C. Cells were washed extensively in cold phosphate-buffered saline (PBS) containing 0.1 M Na₂SO₃. Cells were then resuspended in 0.1 ml of the appropriate fluorescein-conjugated secondary antiserum and incubated for 30 min at 4 °C. All cells were washed extensively in cold PBS-0.1 M Na₂SO₃, resuspended in a small volume of PBS-0.1 M Na₂SO₃ containing 50% glycerol, and observed under a Zeiss microscope equipped for fluorescent microscopy. Results are expressed as percentage of cells positive for fluorescence/total cells counted. Controls for phagocytosis and adherence of Ig to Fc receptors consisted of spleen, thymus and tumour cells incubated in the second antiserum only. Less than 1% of the control cells were positive. All antisera were diluted in PBS-0.1 M Na₂SO₃ to prevent capping. Rabbit anti-mouse Ig was prepared by standard methods and was used at a 1:30 dilution. The fluorescein-conjugated goat anti-rabbit Ig (Meloy, Springfield, Virginia) was diluted 1:40.

*Heavy-chain-specific antisera prepared in goats (Meloy) were diluted 1:20 in PBS-0.1 M Na₂SO₃. The second antisera, fluorescein-conjugated rabbit anti-goat Ig (Meloy) were diluted 1:40 before use.

Table 2 Failure to detect T-lymphocyte antigens on the B10-H-2^a H-4^bp/Wts murine lymphoma

Antisera	% Immunofluorescence			% Cytotoxicity		
	Spleen	Thymus	Tumour	Spleen	Thymus	Tumour
anti-Thy. 1.2	ND	ND	ND	30	100	<1
Rabbit anti-mouse brain*	34	100	90	35	100	<1
Rabbit anti-mouse brain absorbed with thymocytes†	ND	<1	88	<5	<1	ND
Rabbit anti-mouse brain absorbed with tumour cells‡	ND	100	<10	15	90	ND

Indirect immunofluorescence was performed as described in Table 1. Controls for phagocytosis and adherence of Ig to Fc receptors showed that less than 1% of the cells were positive. Dye exclusion cytotoxicity was performed using a minor modification of the technique described by Frelinger *et al.*⁹. Guinea pig complement (Gibco) was the source of complement at a dilution of 1:8. Controls, consisting of cells with antiserum or complement alone, were consistently negative. NIH Contract anti-Thy 1.2 (AKR anti-C3H) antiserum was provided by the Research Resources Branch of NIH. This antiserum killed 100% of the control normal thymocytes at a dilution of 1:10. ND, not determined.

*Rabbit anti-mouse brain antiserum was produced in our laboratory by the technique of Golub¹⁰. For indirect immunofluorescence it was used at a dilution of 1:20 and for cytotoxicity at a dilution of 1:10.

†Rabbit anti-mouse brain antiserum (0.6 ml, 1:10 dilution) was absorbed twice with three normal thymus equivalents for 30 min at 25 °C and used at a dilution of 1:10.

‡Rabbit anti-mouse brain antiserum (0.6 ml, 1:10 dilution) was absorbed twice with 0.2 ml of packed tumour cells for 30 min at 25 °C and used at a dilution of 1:10.

The B10-H-2^a H-4^bp/Wts lymphoma is interesting from another viewpoint. Because only cells or sera from immunologically stimulated B10-H-2^a H-4^bp/Wts mice seem to be able to induce this disease, something involving the combination of the H-2^a and H-4^b chromosomal segments in association with an immune stimulus may make this phenomenon possible. Recently a second B-cell lymphoma, similarly induced in B10-H-2^a H-4^bp/Wts mice, has been established in transplantation and found to bear surface IgM with an idiotype distinct from that of the first tumour. Work is in progress to characterise these tumours and to define the genetic, virological and immunological aspects of these B-cell lymphomas. To add to the well known L₂C guinea pig leukaemia, these murine B-cell tumours provide another excellent model for a similar human malignancy, chronic lymphocytic leukaemia. The murine model has advantages over the guinea pig system in that large experimental groups can be used conveniently, comparisons can be made between different individual tumours and the genetics of the mouse have been much better defined.

We thank Drs James Folds and Marvin Tyan for antisera and Becky Owens for technical assistance.

Induction of antigen-specific human suppressor T lymphocytes *in vitro*

INTENSIVE studies in a variety of animal species have led to the recognition that cell interaction is important for the generation of an immune response¹. The participation of macrophages and of T and B lymphocytes in the process of antibody formation has been demonstrated both *in vivo* and *in vitro*^{2,3}. More recently, attention has been focused on the mechanism(s) regulating the development and expression of immune reactivity, leading to the discovery in a number of animal species of subpopulations of T cells with different functions, such as helper cells (Th) and suppressor cells (Ts) (refs 4-6). Dosch and Gelfand⁷ recently reported that the induction of plaque forming cells (PFC) in human tonsillar or blood lymphocytes is abolished if a (relatively) high antigen dose is used and we have confirmed this finding using the antigens sheep red blood cells (SRBC), ovalbumin (OA) and haemocyanin (Hc)⁸. We have extended these studies and report here the *in vitro* generation of antigen-specific Ts cells in man.

Human peripheral blood lymphocytes (PBL), isolated by density centrifugation⁹ were cultured in tubes for 6 d with or without antigen (SRBC or OA). The cells were then collected, washed and transferred to monolayers of untreated SRBC or of OA-coated SRBC. Primed lymphocytes secreting specific antibody can be recognised by plaque formation. The specificity of this *in vitro* immune response has been firmly documented^{7,8}. The magnitude of the PFC response is antigen dose-dependent, as illustrated in Table 1. Optimal results in the conditions used were obtained at an antigen concentration of $3 \mu\text{g ml}^{-1}$ for OA and at a lymphocyte:SRBC ratio of 1:1. The low number of PFC found in cultures stimulated with a high dose of antigen suggested the generation of suppressor cell activity. However, in these conditions B cells might be inactivated by the high antigen concentration without interference of Ts. To differentiate between these two possibilities PBL were cultured for 24 h with a high dose of OA ($100 \mu\text{g ml}^{-1}$), the cells were collected, washed and added to an equal number of autologous PBL. The cell mixture was cultured in standard conditions (see Table 1) at optimal antigen concentration (OA $3 \mu\text{g ml}^{-1}$) for 6 d and the number of PFC determined. The degree of suppression in these cultures ranged from 62 to 94%, with an average of $80.7 \pm 14.5\%$ (mean \pm s.e.m.) in five different experiments (Table 2). These findings indicate that the low number of PFC generated in cultures

Table 1 Role of antigen concentrations in the PFC response of PBL

OA ($\mu\text{g ml}^{-1}$)	PFC per 10^6 lymphocytes	Lymphocyte:SRBC ratio	PFC per 10^6 lymphocytes
0.3	700(150-1,600)	10:1	299(1,805-560)
1.0	1317(920-2,000)	1:1	1538(1,026-2,100)
3	1418(600-3,000)		
30	230(25-800)	1:10	240(37-620)

For the induction of PFC to OA and SRBC, cultures were set up in 17×100 mm tissue culture tubes (Falcon) containing 5×10^6 PBL in 10 ml RPMI-1640 medium supplemented with 10% heat inactivated AB serum (of a pooled stock of three donors), penicillin (100 IU ml^{-1}), streptomycin ($100 \mu\text{g}$), Fungizone ($25 \mu\text{g ml}^{-1}$), L-glutamine (2 mM) and antigen at different concentrations. When SRBC were used as antigen, the AB serum was absorbed three times with SRBC to prevent pseudo-plaque formation¹⁰. The cultures were kept in a humidified atmosphere of 5% CO_2 in air. After culture for 6 d cells were collected, washed twice in RPMI-1640 at 4°C and assayed for PFC according to the method of Dosch and Gelfand⁷. The data shown are expressed as the arithmetical mean of values obtained in 10 individual experiments. Within each experiment determinations at the various antigen doses were done in six fold. Values in parentheses represent the ranges.

Table 2 Effect of *in vitro* induced suppressor cells on the anti-OA PFC response

Expt no.	Day 1 PBL*	Day 2 Suppressor cells†	Day 6 PFC per 10^6 lymphocytes	% Suppression†
1	10×10^6	—	1,810	
	5×10^6	5×10^6	245	86.5
2	10×10^6	—	737	
	5×10^6	5×10^6	233	68.3
3	10×10^6	—	857	
	5×10^6	5×10^6	48	94.3
4	10×10^6	—	1,236	
	5×10^6	5×10^6	91	92.6
5	10×10^6	—	5,357	
	5×10^6	5×10^6	2,020	62.3

*In control experiments 10^7 PBL were treated as outlined below except that the antigen dose used was OA $3 \mu\text{g ml}^{-1}$.

†In order to generate suppressor cells 10^7 lymphocytes were cultured in the presence of OA $100 \mu\text{g ml}^{-1}$ in 10 ml RPMI-1640 containing antibiotics L-glutamine and 10% AB serum for 24 h. Cells were collected, washed twice in RPMI-1640 and 5×10^6 of these cells were added to 5×10^6 PBL that had been primed with OA $3 \mu\text{g ml}^{-1}$ 24 h earlier and cultured for an additional period of 5 d.

‡The % suppression was calculated according to the formula:

$$100 - \frac{\text{No. PFC per } 10^6 \text{ lymphocytes in suppressed cultures}}{\text{No. PFC per } 10^6 \text{ lymphocytes in normal cultures}} \times 100$$

with high doses of OA is the result of a suppressive action of PBL induced by contact of these cells with OA in high concentrations. To identify the cell type responsible for the suppression of *in vitro* antibody response, PBL were depleted of adherent cells and separated into T and non-T cells (see legend to Table 3). The isolated T lymphocytes and the non-T cells (B and null cells) were supplemented with 5% adherent cells and incubated for 24 h with OA $100 \mu\text{g ml}^{-1}$. The cells of these two different populations were then washed and added to normal PBL primed with OA $3 \mu\text{g ml}^{-1}$ 24 h

Table 3 The nature of the *in vitro* induced suppressor cells

Cell mixtures added to PBL with antigen	Treatment	PFC response to OA (PFC per 10^6 lymphocytes)		
		Expt 1	Expt 2	Expt 3
T cells	—	906	686	616
Non-T cells*	—	—	—	—
T cells	100 μg OA	267(70.5)†	240(65)	185(70)
Non-T cells	—	—	—	—
T cells	—	715(21.1)	750(—9.3)	608(1.3)
Non-T cells	100 μg OA	—	—	—

PBL, isolated by density gradient centrifugation, were depleted of non-lymphoid mononuclear cells by incubation in Falcon flasks (45 min at 37°C) in RPMI-1640 supplemented with 20% foetal bovine serum (PBL_{acc}). The adherent cells (monocytes, macrophages) were recovered by gently scraping with a rubber policeman, washed twice in Ca^{2+} - and Mg^{2+} -free Earle's balanced salt solution supplemented with EDTA (0.02 mM) and resuspended in culture medium. The non-adherent cells were separated into T cells and non-T cells according to the method of Moretta *et al.*⁶. The isolated T cells and the non-T cells (B and null cells) were supplemented with 5% adherent cells and incubated for 24 h with OA $100 \mu\text{g ml}^{-1}$ or without antigen in culture medium (see Table 1). The cells were then washed twice with RPMI-1640. Since it has been found that the concentration of OA necessary for the induction of maximal numbers of PFC increases with the numbers of T cells present in a given cell suspension^{7,8} T cells and non-T cells, previously incubated with OA $100 \mu\text{g ml}^{-1}$ were reconstituted with normal non-T cells and T cells respectively to obtain cell mixtures with T:B ratios equally to those of normal PBL suspension. 5×10^6 Lymphocytes of these cell mixtures were added to 5×10^6 PBL_{acc} reconstituted with 5% macrophages and incubated with OA $3 \mu\text{g ml}^{-1}$ 24 h earlier. After 5 d PFC assay was performed⁷.

*T-cell contamination in the non-T cell population was 3.5%, < 0.5% and 1.5% respectively in Expts 1, 2 and 3.

†The values in parentheses represent the percentages of suppression calculated according to the formula in the legend to Table 2.

earlier (the suppressive effect in these conditions is optimal, data not shown). After 5 d of culture PFC assay was performed. The results (Table 3) show clearly that after incubation for 24 h with a high dose of OA, non-T cells are not able to suppress PFC response *in vitro*. In contrast, suppressive activity can be induced in identical conditions in a purified T-lymphocyte population. This might be interpreted as the result of activation or generation of Ts. It was realised that a high concentration of antigen, carried over by cells previously incubated with the antigen, might have induced B-cell unresponsiveness. There are, however, several arguments that counter this possibility. First, in contrast to T cells, non-T cells after incubation with OA $100\text{ }\mu\text{g ml}^{-1}$ failed to suppress the anti-OA PFC response. Therefore, neither B lymphocytes nor adherent cells (macrophages) are able to carry over sufficient amounts of antigen to inhibit PFC formation. Antigen carry-over by T cells is therefore highly unlikely. Second, Cobi Heynen *et al.* (in preparation) found evidence that a major subpopulation of T cells bearing a receptor for the Fc fragment of IgM ($\text{T}\mu$) is not able to suppress an anti-OA PFC response after treatment with high concentrations of this antigen. Taken together these results fail to support induction of B-cell unresponsiveness by the carry-over of high antigen concentrations as the predominant mechanism of the observed suppression.

Table 4 Specificity of suppression by PBL treated with OA

PBL* treated with ($100\text{ }\mu\text{g ml}^{-1}$)	Antigen in culture	PFC response against	% Suppression of PFC response†		
			Expt 1	Expt 2	Expt 3
OA	SRBC	SRBC	-8	26.7	10.8
OA	OA	OA	92	92.6	73.9

*Suppressor cells were generated as described in the legend to Table 2.

†Percentage suppression was calculated according to the formula in Table 2 legend.

The suppression obtained in our system is antigen specific, as Ts induced with OA did not suppress PFC formation against SRBC (Table 4). Also, Ts induced by incubation with high numbers of SRBC specifically suppress PFC response against SRBC but have no effect on OA-specific PFC (data not shown). It should be emphasised that the suppressive effect described here is on the IgM response. Since it has been found in mice that IgM responses are more difficult to suppress than secondary IgG formation^{11,12}, it would be interesting to study the effect of induced Ts on restimulated cultures. Attempts are currently being made to obtain an anamnestic immune response *in vitro*.

The possibility of inducing *in vitro* antigen specific suppressor cells might have far reaching implications in immune manipulation in man.

Glutamate neurotoxicity and Huntington's chorea

McGEER and McGeer¹ recently reported that an intrastriatal injection of glutamate results in biochemical changes in brain similar to those associated with Huntington's chorea. They postulated that glutamate, a putative excitatory transmitter and an 'excitotoxin' abundantly present in brain may have a role in the pathophysiology of Huntington's chorea. Their evidence for this postulate must be considered very preliminary, however, as the biochemical changes induced by a 50 nmol dose of glutamate were not striking and it was not determined whether these changes were accompanied by neuronal degeneration¹. We have injected various doses of glutamate directly into the rat striatum and examined the striatum for histopathological changes 21 d later. Here we report that doses of glutamate much higher than 50 nmol definitely cause striatal neurones to degenerate, whereas no neurotoxic reaction results from injecting equally high doses of control compounds such as NaCl or γ -aminobutyric acid (GABA).

Glutamate and its several neuroexcitatory analogues, when administered systemically to experimental animals, destroy neurones in certain brain regions which lack adequate blood brain barriers to these compounds². Certain analogues, such as kainic acid (KA), *N*-methyl aspartic acid (NMA) and homocysteic acid (HCA) are more powerful than glutamate in either excitatory or toxic activity^{2,3}. The introduction of tiny amounts of these potent analogues by microinjection directly into the rat brain destroys local neurones without damaging axons passing through or terminating in the region⁴; lesion size is directly proportional to the known excitatory potency of the injected compound, the order of potencies being KA>NMA>HCA. A single injection of KA (5-10 nmol) into rat striatum results in rapid loss of striatal neurones⁵⁻⁷ and specific changes in transmitter enzymes^{1,5} similar to those known to occur in Huntington's chorea. This suggests that the more potent analogues of glutamate may be useful tools for studying Huntington's chorea. The findings reported here are consistent with the related but potentially more important proposal¹ that glutamate itself might have a role in the loss of striatal neurones in Huntington's chorea.

Twenty-four adult male Wistar rats (Harlan) weighing 250 g were used in these experiments. Monosodium L-glutamate (Glu) and GABA were obtained from Sigma. All compounds were introduced stereotactically into the striatum as previously described⁷ through a 30 gauge cannula by the method of Swanson *et al.*⁸. Glutamate was dissolved in sterile H₂O in various concentrations to permit testing four doses (50, 150, 500 and 1,000 nmol) in a volume of 1 μ l. Aqueous solutions of two control compounds, NaCl and GABA were administered at 1,000 nmol to match the highest dose of glutamate used. The glutamate and GABA solutions were at pH 7.0 and NaCl was at pH 6.1. At least four animals were used to test each dose of each compound. Each animal, under pentothal anaesthesia, was given a single 1- μ l injection of solutions containing one of the three compounds. The solutions were injected slowly over a 5-min

period and the cannula was left in place for an additional 10 min before removal to prevent retrograde movement of the injected solution up the cannula tract. Animals were killed 21 d after injection by glutaraldehyde-paraformaldehyde perfusion fixation under chloralhydrate anaesthesia and 3/4-mm serial slabs collectively encompassing the entire striatum were additionally fixed in osmium tetroxide and processed for combined light and electron microscopic examination by methods previously described^{9,10}.

None of the striata injected with GABA or NaCl had detectable histopathological changes other than minor changes expected from cannula insertion. The injection site could be identified by a small scar, but this was surrounded on all sides by healthy looking neurones in normal numbers. The appearance of a GABA injection site is illustrated in Fig. 1. The failure of NaCl injection to induce a neurodegenerative reaction in rat brain is reported elsewhere²².

In the striata of animals which received 50 or 150 nmol of glutamate there were indications about the injection site of a more extreme tissue reaction than was induced by GABA or NaCl, but definitive evidence for neuronal loss was lacking. It should be noted, of course, that the deletion of a very small number of neurones would be difficult to demonstrate with any confidence. All animals which received 500 nmol of glutamate had a decidedly larger area of tissue disturbance which we judged to be evidence for a neurotoxic reaction, based on the abundant reactive cells present and of the reduced number of neuronal profiles detectable. We estimated that approximately 5–10% of the total striatal population of neurones was deleted by 500 nmol of glutamate. A much larger area of tissue disturbance was evident in all animals which had received an injection of 1,000 nmol of glutamate. Approximately 30% of the total striatal neuronal population was deleted by this dose of glutamate. There were numerous reactive cells distributed about the lesioned area and neuronal profiles were absent but axonal bundles remained intact (Fig. 2). Thus, the effect seemed to be the characteristic dendrosomatotoxic but axon-sparing type of neurodegenerative effect which excitotoxic compounds are known to produce^{4,5,7,10,11}.

Our observation that an intrastriatal injection of glutamate destroys striatal neurones is consistent with the finding of McGeer and McGeer¹ that injecting glutamate into the

Fig. 1 A light micrograph depicting a region of striatum where 1000 nmol of GABA was injected 21 d previously. A scar is detectable where the cannula tip penetrated the striatal tissue but healthy neurones in normal numbers surround the scar ($\times 280$).

Fig. 2 A light micrograph depicting a region of striatum about 500 μ m away from the site where 1,000 nmol of Glu was injected 21 d previously. Although all intrinsic striatal neurones have degenerated beyond recognition, bundles of axons passing through the striatum remain intact and have a normal appearance ($\times 280$).

striatum causes a loss of the transmitter-synthesising enzymes, cholineacetyltransferase and glutamic decarboxylase which are considered markers for striatal neurones. It is puzzling, however, that we detected significant neuronal loss from doses of glutamate substantially higher than the 50 nmol which produced enzyme changes in the experiments of McGeer and McGeer. Presumably, a reduction in transmitter marker enzymes would occur only to the extent that neurones containing these enzymes are destroyed. Additional studies are needed to clarify whether such an expectation is warranted and to explain the apparent discrepancy between our findings and those of McGeer and McGeer¹.

Although our results suggest that glutamate is a weak neurotoxin compared to KA, we suspect this may be due in part to mechanisms in normal brain which function to protect neurones more effectively from glutamate than from KA. For example, the high affinity uptake system which, by removal of glutamate from excitatory receptor loci may control its excitotoxic potential, is relatively inaccessible to KA¹². This inactivation system may be efficient enough in normal striatum to prevent glutamate, unless injected in large amounts, from destroying local neurones. If, in the course of an individual's life, this vital homeostatic mechanism became dysfunctional, however, glutamate released at excitatory synapses might gradually accumulate in the synaptic cleft region in sufficient concentration to cause excitotoxic degeneration of glutamergically innervated neurones. In view of accumulating evidence^{13–17} suggesting that striatal neurones receive massive input from terminals utilising glutamate as transmitter, it is reasonable to propose¹ that glutamate may be involved in the degeneration of striatal neurones in Huntington's chorea. Indeed, for heuristic purposes, we would advance the more specific proposal that an adult-onset disturbance in the transport system for intracellular reuptake of glutamate might underly this neurodegenerative syndrome. This may be a testable hypothesis, depending on the technical feasibility of assaying the high affinity glutamate uptake capacity of striatal tissue obtained at autopsy from brains of patients with Huntington's chorea.

Morphine and β -endorphin inhibit release of noradrenaline from cerebral cortex but not of dopamine from rat striatum

β -ENDORPHIN is a large polypeptide containing 31 amino acid residues, the first five of which are identical with methionine-enkephalin¹ which has potent naloxone-sensitive analgesic properties² and opiate activity in receptor binding assays in guinea pig ileum^{3,4}. It has been shown that morphine depresses the potassium-induced release of ³H-noradrenaline in the rat cerebral cortex⁵ and of ³H-dopamine in the rat striatum⁶. These effects are blocked by the opiate antagonist naloxone and are probably due to the activation of presynaptic inhibitory opiate receptors located in noradrenergic and dopaminergic nerve endings of the rat brain. While met-enkephalin reproduced the effects of morphine in rat cortex slices⁷, it failed to reduce the release of dopamine from the rat striatum⁶. In view of these results, it was considered of interest to examine under similar experimental conditions, the effects of morphine and of β -endorphin on the potassium-stimulated release of ³H-dopamine from striatal slices and of ³H-noradrenaline from cerebral cortex slices of the rat⁸. In contrast to Loh *et al.*⁶, who more recently have not been able to reproduce their data (E. L. Way, personal communication), we find no evidence for the inhibition of the potassium-stimulated overflow of ³H-dopamine by β -endorphin and morphine in the striatal slices of the rat.

Male rats of 150 to 200 g were killed by decapitation. Slices of 0.3 mm thickness were obtained from the rat corpus striatum and occipital cerebral cortex with a McIlwain tissue chopper. The slices were transferred to the incubation medium in an open lucite cylinder with a nylon mesh fitted to the bottom as a small basket⁹. The whole system was placed in a 30-ml beaker with 5 ml of Tyrode solution containing 61 μ M ascorbic acid and 69 μ M EDTA equilibrated with a 5% CO₂ in O₂ and maintained at 37 °C.

Striatal and occipital cortex slices were incubated for 30 min with 2 μ M ³H-dopamine and 0.9 μ M (\pm) ³H-noradrenaline, respectively. The tissue was washed by transferring to successive beakers, and the spontaneous outflow of radioactivity into the medium was followed for 65 min before the release of the labelled transmitter was elicited by 1 min exposure to 20 mM K⁺. Two periods of stimulation with K⁺ were applied in each experiment, S₁ and S₂. The interval between S₁ and S₂ was 40 min. The overflow of the labelled transmitter elicited by

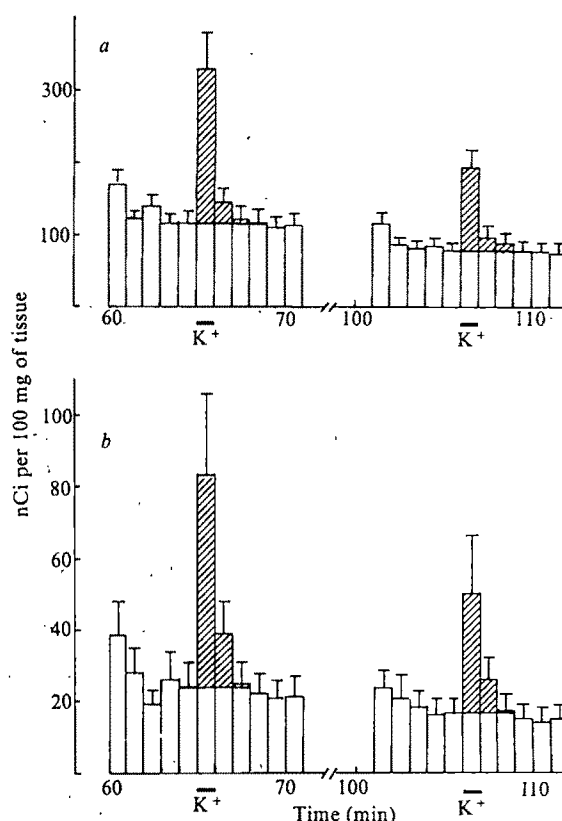

Fig. 1 Release of radioactivity from slices of rat corpus striatum and occipital cortex during exposure to 20 mM K⁺. Ordinate, fraction of the total radioactivity in the tissue released per min (nCi per 100 mg of tissue), abscissae, time (in min) after the end of the incubation with either ³H-noradrenaline (NA) or ³H-dopamine (DA). The open columns represent the spontaneous outflow of total radioactivity in 1-min samples. The horizontal bar indicates the 1-min exposure to 20 mM K⁺ which was repeated 40 min later. The shaded areas indicate the increase in release of radioactivity induced by K⁺. *a*, release of ³H-DA from slices of rat corpus striatum; values are the mean \pm s.e.m. ($n = 13$); *b*, release of ³H-NA from slices of rat occipital cortex, values shown are the mean \pm s.e.m. ($n = 7$). Tissue tritium content at the end of the experiment was $3,546 \pm 616$ nCi per 100 mg ($n = 13$) in the striatum and 938 ± 98 nCi per 100 mg ($n = 7$) in the occipital cortex; n = number of experiments per group.

potassium was expressed as per cent of the tissue stores: total nCi released as a fraction of the total radioactivity present in the tissue at the onset of stimulation⁹. Figure 1 shows the pattern of ³H-transmitter release elicited by each of the two consecutive periods of exposure to potassium in the rat striatum (Fig. 1*a*) and in rat occipital cortex slices (Fig. 1*b*).

Table 1 shows that in contrast with the cerebral cortex slices,

the release of the labelled transmitter elicited by K^+ from the rat striatum was not entirely calcium-dependent. In the absence of calcium, the release of 3H -noradrenaline induced by potassium from the cerebral cortex was practically abolished (Table 1). In the striatum, however, as much as 40% of the release elicited by K^+ was found to be calcium-independent. Figure 2 shows that morphine and β -endorphin significantly decreased the K^+ -induced release of 3H -noradrenaline from the cerebral cortex. The effects of both opiate receptor agonists were reversed in the presence of naloxone (Fig. 2). In contrast with these results, neither morphine nor β -endorphin were able to inhibit the release of 3H -dopamine from rat striatal slices (Fig. 3) even when tested in concentrations higher than those found to be effective in the cerebral cortex (compare Figs 2 and 3).

Our results support the view that presynaptic inhibitory opiate receptors are present in noradrenergic nerve endings of the rat cerebral cortex. In addition, we found that β -endorphin stimulates these presynaptic opiate receptors and that it is at least 10 times more potent than morphine in reducing 3H -noradrenaline release. The failure of morphine and of β -endorphin to reduce the release of 3H -dopamine from the striatum represents a conflict of evidence with a previous report⁶. It should be noted, however, that in our experimental conditions, we stimulated release with a 1 min exposure to 20 mM K^+ , while in the previous publication, 53 mM K^+ during 20 min was used⁶. We consider our experimental conditions (short pulse of a moderate potassium concentration) to mimic nerve stimulation more closely than a prolonged exposure to a rather high concentration of K^+ .

During a 1 min exposure to 20 mM K^+ , approximately 5% of the total tissue radioactivity was released from the striatum (Table 1). In separate experiments in which the slices were exposed to 40 mM K^+ for 5 min, $36.27 \pm 2.84\%$ of the total tissue radioactivity was released from the striatum (mean \pm s.e.m. of four experiments). We consider that such a massive release of 3H -dopamine is not an adequate model for studies on transmitter release. It should be noted that for similar studies in the peripheral nervous system the fraction of the total tissue radioactivity released by nerve stimulation does not exceed 5% of the tissue stores⁹⁻¹². Attention should be drawn to the fact that even for a short lasting exposure to as little as 20 mM K^+ , more than one-third of the labelled transmitter released from the striatum represented a calcium-independent release. Under similar experimental conditions, the release of 3H -noradrenaline from the rat cortical slices was entirely calcium-dependent.

Fig. 2 Effects of morphine and β -endorphin on the release of 3H -noradrenaline elicited by potassium in the rat occipital cortex. Ordinate, ratio of fractional release (S_2/S_1); S_1 corresponds to the first 1-min exposure to 20 mM K^+ and S_2 to the second obtained 40 min after S_1 . Morphine was added 25 min before S_2 ; β -endorphin 10 min before S_2 and naloxone 35 min before S_2 . Values shown are mean \pm s.e.m. of 4-7 experiments per group.

Fig. 3 Effects of morphine and β -endorphin on the release of 3H -dopamine elicited by potassium in rat striatal slices. Ordinate, ratio of fractional release (S_2/S_1); S_1 corresponds to the first 1-min exposure to 20 mM K^+ and S_2 to the second obtained 40 min after S_1 . Morphine was added to the medium 25 min before S_2 , and β -endorphin 10 min before S_2 . Values shown are mean \pm s.e.m. of 6-11 experiments per group.

Our results regarding the 40% calcium-independent release of 3H -dopamine from the striatum are in disagreement with previous reports which demonstrated either total calcium dependence^{13,14} or only a 15% calcium-independent component¹⁵, although a 33% calcium-independent component for the potassium-induced release of 3H -dopamine from the rat striatum was reported by Dismukes and Mulder¹⁶. We have found that the extent of the calcium-independent component for 3H -dopamine release from the striatum (40%) was not affected by inhibition of monoamine oxidase *in vitro* or *in vivo* with pargyline. Under our experimental conditions 3H -dopamine release originated from reserpine-sensitive storage sites in the striatum. In support of this view it was found that pretreatment with reserpine (5 mg kg⁻¹, 24 h before the experiment) reduced considerably the ability of the striatum to take up and store 3H -dopamine. In these experiments, exposure to K^+ was practically ineffective in eliciting 3H -dopamine release. It is concluded that β -endorphin and morphine reduce noradrenaline release from the rat cerebral cortex through the stimulation of presynaptic opiate receptors. Neither morphine nor β -endorphin reduced the release of dopamine from the rat striatum. In addition, a significant calcium-independent release of 3H -dopamine has been found in the rat striatum.

The magnitude of the calcium-independent component of 3H -dopamine release may vary with the strength and duration of the depolarising stimuli. Consequently, it is possible that the recent controversial reports on the effects of dopamine agonists and neuroleptics on dopamine release from the rat striatum may reflect experimental conditions with different degrees of calcium-independent release of 3H -dopamine^{13-14,16-18}. As a result of these conflicting reports, the presence of presynaptic dopaminergic receptors and their role in the regulation of dopamine release from nerve endings in the central nervous system remains an open question¹⁹.

ACETYLCHOLINE (ACh) is released from stimulated nerve terminals in packets or quanta, each containing roughly 10,000 molecules^{1,2}, but we still do not know how the quanta are formed. A widely accepted hypothesis is that the ACh contained in vesicles found in the nerve terminal is released by exocytosis, while an alternative suggestion is the gated channel hypothesis. This takes into account the fact that the ACh which seems to be in free solution in millimolar concentrations in the terminals⁴ is probably the source of the ACh which leaks molecule by molecule from the resting terminals (only a small fraction of the spontaneous release is quantal^{5,6}). Other evidence against the vesicle hypothesis is that when nerves are exposed to radioactive precursors, the free ACh is labelled first, and with stimulation the newly synthesised ACh is released preferentially⁷. The free ACh could also be released in packets if stimulation opens gates on channels through which ACh diffuses from the terminals; with each opening of a channel, about 10,000 transmitter molecules might escape by moving out of the terminal down a concentration gradient. One way to test the gated channel hypothesis is to change abruptly the concentration of free ACh in the terminal, and so change the number of ACh molecules per quantum. This has been achieved in a molluscan cholinergic neurone by injecting acetylcholinesterase into the cell body. The enzyme diffuses down to the terminals, hydrolyses the free ACh, and produces a transmission block⁸. Unfortunately, in this preparation it is not possible to determine the quantal size, so it is not certain that the block occurs because the quanta become smaller. Quantal size is readily estimated at the vertebrate neuromuscular junction, but it is not possible to inject substances into the fine nerve terminals and there does not seem to be a feasible way to

To avoid problems with changing numbers of quanta released with each stimulus, spontaneously occurring miniature endplate potentials (m.e.p.s) were used to estimate quantal size. The protocol for the first set of experiments was as follows; a sciatic nerve-sartorius muscle preparation from the frog *Rana pipiens* was immersed in Ringer solution made hypertonic by the addition of 250 or 500 mM sucrose. After a one hour equilibration a microelectrode was inserted at the endplate and m.e.p.s were recorded. The microelectrode was then withdrawn until it was just outside of the fibre, the extracellular solution was aspirated from the bath, a fresh solution of normal tonicity was passed over the preparation, the micro-electrode was reinserted, and m.e.p.s were recorded once again. The change in solution and repenetration took less than 20 s. The m.e.p.p. amplitudes were measured before and after the change in tonicity.

Successful experiments met a set of criteria; (1) the fibre was seen clearly and visual landmarks were good, so the probability was high that the microelectrode was reinserted into the same fibre; (2) the membrane potential did not deviate by more than 3 mV during the penetrations or with the repenetration, so the amplitudes did not have to be corrected for changes in membrane potential; (3) m.e.p.p. frequency was sufficiently low for some individual m.e.p.ps to be distinctly separated in time from their fellows, so that their amplitudes could be accurately measured. This criterion might seem to be impossible to meet. Hypertonic solutions are known to cause massive increases in m.e.p.p. frequency, an increase in tonicity of 100 to 150 mOsm often produces frequencies too high for the accurate counting of events; the records are far too jumbled for accurate amplitude measurements. It has been found, however, that with increases in tonicity above 450 mOsm l^{-1} m.e.p.p. frequency begins to decline once again¹¹. Therefore, in Ringer containing 250 or 500 mM sucrose, some junctions can be found at which there are sufficient numbers of free-standing m.e.p.ps for accurate amplitude measurements.

From many attempts, seven experiments met the three criteria. An example is illustrated in Fig. 1. There is no significant difference between the mean amplitudes in hypertonic and in normal Ringer's solution. In both solutions, the amplitude

The Ringer contained (in mM): 110 NaCl, 2.0 KCl, 2.5 CaCl₂, 6 Na-Ntris- (hydroxymethyl) methyl-2-aminoethanesulphonic acid (TES) at pH 7.4 and 10⁻⁶ g ml⁻¹ neostigmine methylsulphate. Resting potential -78 mV. The m.e.p.ps were recorded on tape at 7½ s⁻¹ and played back at 1½ inch s⁻¹ to a Hewlett Packard ink writer; *b*, amplitude histograms of the m.e.p.ps recorded in one experiment in Ringer (mean ± s.e.m. 0.45 ± 0.24, *n* = 755 (upper trace) and in Ringer plus 500 mM sucrose (0.47 ± 0.26, *n* = 665, lower trace); *c*, the cumulative distribution of amplitudes in the two solutions. The cumulative relative frequency, *f*, is plotted as a function of the amplitudes. The probability of the deviation between the two distributions occurring by chance is greater than 0.15.

distribution is skewed toward higher values and neither fits a normal probability distribution function. Therefore, the two distributions were compared further by plotting the cumulative probability distribution functions of the amplitudes and then comparing the two by the Kolmogorov-Smirnov statistic. The differences between the two are readily attributed to chance variation ($P > 0.1$). The records were carefully examined by eye to see if there was a transient change in amplitude immediately following the solution change, but none was detected. Furthermore, the regression line for the first 50 or 100 m.e.p.p. amplitudes following the solution change were calculated. The slopes of the lines were indistinguishable from zero (for 100 events in the experiment in Fig. 1, $b = 0.0001 \pm 0.00027$). Similar results were obtained in the six other successful experiments (in two of these the transition was in the opposite direction, from normal to hypertonic Ringer).

Before concluding that changes in terminal volume have no effect on quantal size, it is necessary to rule out the possibility that changes in tonicity have other, compensating effects on endplate physiology, so that real changes in the amounts of ACh released are not detected in the experiments. An increase in tonicity might decrease the sensitivity of the endplate to ACh, then more ACh could be released in the hypertonic solution without producing an obvious increase in amplitude. Nastuk and Parsons¹² studied the depolarisation produced by 0.011 mM carbamylcholine in normal Ringer and in Ringer plus 300 mM sucrose, and concluded that the sensitivity was unchanged. Another possibility is that the change in muscle fibre volume produces substantial changes in the cable properties of the endplate region. If this occurred, transient, identical pulses of ACh might generate the same conductance change and current flow at the endplate, and nonetheless give m.e.p.s of different amplitudes because of altered cable properties. The initial experiments suggested that substantial changes in cable properties are unlikely, because the shape of the m.e.p.s is so similar in the normal and in the hypertonic solutions. This was checked by eye and also by measuring the half-times for the decay of the m.e.p.s (in the example shown in Fig. 1, normal Ringer = 13.3 ± 0.46 ms, $n = 22$; hypertonic Ringer = 13.2 ± 0.57 ms, $n = 29$).

This possibility was tested further by using the two micro-electrode method for voltage clamping the endplate, so that the amplitudes of the miniature endplate currents (m.e.p.s) could be measured¹³. The disadvantage of this method is that there is a somewhat greater delay between the solution change and the reinsertion of two electrodes than in the previous experiments; in other respects the protocols were identical.

Figure 2 shows m.e.p.s at various holding potentials at the same endplate in normal and in hypertonic solution. The m.e.p.s have a slightly lower mean amplitude in hypertonic than in normal Ringer. (This result might be anticipated because the muscle fibre will also shrink in the hypertonic solution, increasing $[K]_i$ and $[Na]_i$, thereby making the reversal potential for the e.p.p. somewhat more negative. But this explanation glosses over a complicated series of possibilities. For example, the change in intracellular ion concentrations will change the surface potential on the inner side of the sarcolemma¹⁴, and this would be expected to change membrane ionic conductances.) The important point is that there was no indication of even a transient increase in the m.e.p.s following the transition from hypertonic to normal Ringer, nor was there any notable change in the time course of the m.e.p.c. Similar results were obtained in two additional voltage clamp experiments.

Thus, abrupt change in tonicity, which must produce almost stepwise alterations in nerve terminal volume, do not change m.e.p.p. amplitudes or m.e.p.s in the direction expected if the amount of ACh released per quantum depends on the concentration of free ACh in the cytoplasm of the terminal. From the present experiments it is still conceivable that quantal size depends upon free ACh, but this requires that following a substantial change in concentration—probably at least two-fold

Fig. 2 *a*, Examples of the m.e.p.s in Ringer (right hand trace) and in Ringer plus sucrose (left hand trace) at a holding potential of -121 mV. The solutions and the method of data collection are given in the legend to Fig. 1. *b*, M.e.p.s recorded in a preparation in Ringer (●) and in Ringer plus 500 mM sucrose (○). The vertical bars indicate \pm the s.e.m.

—the terminal is capable of readjusting to normal levels of ACh within one or two minutes. When these observations are taken together with the evidence that quantal size does not vary with changes in the membrane potential of the nerve terminals¹⁵, as would be expected if free ACh were released as a cation through a channel, then the balance is overwhelmingly in favour of a release mechanism which does not depend upon the free ACh concentration. The vesicle hypothesis, with suitable modifications to account for such observations as the preferential release of newly synthesised transmitter, offers a most reasonable alternative.

Benzodiazepines specifically modulate GABA-mediated postsynaptic inhibition in cultured mammalian neurones

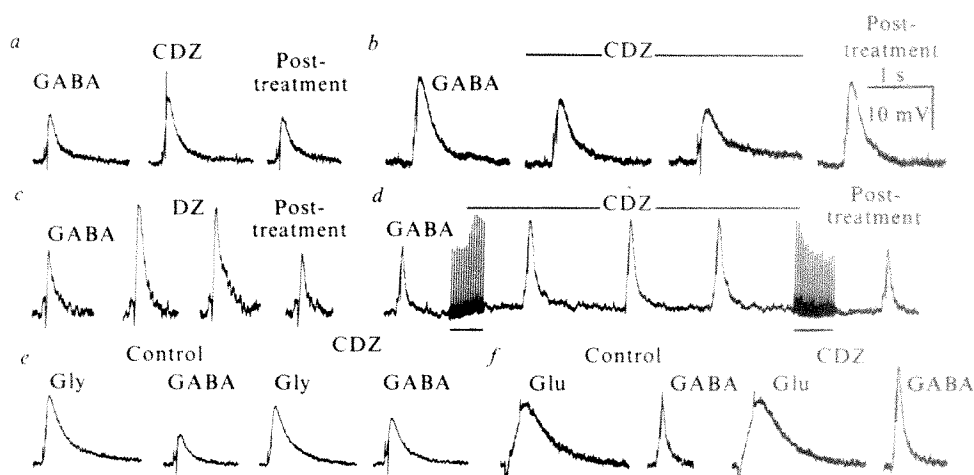

BENZODIAZEPINES (BDZ) such as diazepam (DZ) and chlordiazepoxide (CDZ) are commonly used anticonvulsants, muscle relaxants, antianxiety agents and hypnotics. The cellular mechanisms underlying these clinically important effects have not been established, but attention has been focused on the effect of BDZ on pre- and postsynaptic responses to the putative neurotransmitter amino acids, specifically glycine (Gly)^{1,2} and γ -aminobutyric acid (GABA)³⁻⁷. An effect of BDZ on postsynaptic Gly receptors was suggested by the finding that BDZ reduce strychnine binding to central nervous system (CNS) synaptic membrane fractions *in vitro*², but physiological studies, *in vivo*, have provided little support for such an interaction with Gly³. BDZ have been reported (1) to facilitate presynaptic inhibition in the spinal cord^{4,5}, at least partially GABA-mediated⁸⁻¹⁰; (2) to facilitate GABA-mediated pre- and postsynaptic inhibition in the cuneate nucleus⁶; (3) to mimic the presynaptic action of GABA on preganglionic nerve terminals¹², and (4) to antagonise^{13,14} and to enhance^{15,16} the postsynaptic action of GABA on CNS neurones. It has also been suggested that BDZ alter GABA metabolism^{4,5} or mobilise GABA from neuronal storage sites¹⁷, and BDZ have been demonstrated to bind specific receptors on synaptosomal membrane preparations derived from rat brain¹⁸, an effect which is independent of amino acid receptors. Thus, it is uncertain whether BDZ action is GABA or Gly receptor-mediated, due to an alteration of GABA metabolism, or due to direct binding to a specific receptor which binds BDZ. We have studied the effect of DZ and CDZ on amino acid-mediated postsynaptic responses in cultured mammalian spinal cord neurones and report that the BDZ selectively modify GABA-mediated postsynaptic inhibition in a dose-dependent fashion, augmenting the response at low doses and antagonising the response at higher doses.

Cultures were prepared from spinal cords removed from 13-14-d-old foetal mice as described previously¹⁹, and were grown on collagen-coated 35-mm dishes for 5-8 weeks before the study. Electrophysiological recordings were made on a

modified stage of an inverted phase microscope at 37 °C. All recordings were made in normal growth medium (90% minimal Eagle's medium/10% horse serum) to which $MgCl_2$ was added (final Mg^{2+} concentration of 10 mM) to suppress spontaneous activity and allow a clearer recording of postsynaptic responses. BDZ and amino acids were iontophored using a constant current device and high resistance 8-tube micropipettes (50-100 M Ω) filled with GABA (0.5 M, pH 3.5), Gly (0.5 M, pH 3.5), glutamate (Glu) (0.5 M, pH 8.6), (all from Sigma), DZ (10 mM, pH 3.5) and CDZ (100 mM, pH 3.5) (Hoffman-Roche, Nutley, New Jersey).

Both CDZ (Fig. 1a, d) (15 cells) and DZ (Fig. 1c) (6 cells) rapidly and reversibly augmented the response elicited by the iontophoresis of GABA (Fig. 1d). This augmentation could frequently be produced by simple diffusion of BDZ from the pipette tip but usually required passage of 1-5 nA of positive current. When augmentation was achieved, if additional current (1-10 nA) was passed through the BDZ pipette, antagonism of the GABA response was produced (Fig. 1b). The entire range of augmentation and inhibition was usually obtained without any alteration in resting membrane potential or input resistance, but a direct effect of BDZ was occasionally obtained (five cells), consisting of depolarisation and increase in conductance (not illustrated). The effect of these agents was specific for GABA since the responses to Gly (Fig. 1e) and Glu (Fig. 1f) were not augmented by CDZ application despite clear augmentation of GABA responses (five cells). The nature of this action of BDZ on the GABA response is unclear. One possible mechanism for augmentation of the response could involve an inhibition of the uptake of GABA, thus prolonging GABA synaptic action. This is unlikely as such an effect would be expected to prolong the time course of the response and this does not occur either with augmentation (Fig. 2a) or with antagonism (Fig. 2b), and would not explain the high dose antagonism of the response. The specificity of the interaction between BDZ and GABA suggests, however, that a direct effect of BDZ on the Cl^- conductance mechanism used by GABA and Gly²⁰ is unlikely; rather, the most likely site of action is at the GABA receptor with a modification of the affinity of the receptor for GABA. Such a conclusion is supported by initial analysis of the augmenting effect of CDZ on GABA dose-response curves; this effect is associated with a parallel shift to the left without alteration of the V_{max} para-

Fig. 1 Effect of benzodiazepines on amino acid responses in cultured mammalian spinal cord neurones. Intracellular recordings were made using 3M KCl micropipettes (25-40 M Ω) with the membrane potential hyperpolarised to -90 mV. Amino acid responses were elicited with 50 ms pulses of appropriate polarity while BDZ were applied with a steady cationic current. Under these conditions, the reversal potential for all amino acid responses is more positive than -30 mV, and thus all responses are depolarising. CDZ [as] and DZ [cs] reversibly augment the GABA response at low iontophoretic currents and reversibly depress the GABA response at higher currents [bs] (illustrated for CDZ only). A continuous record of augmentation of GABA responses by CDZ is shown in d. The penwriter is slowed (see bars below d) at onset and offset of CDZ current (time calibration bar, 5 s). The response to Gly (e) and Glu (f) are not augmented by CDZ despite clear augmentation of the GABA response. Calibration bars apply to all penwrite traces except as described in d.

Fig. 2 Time course of GABA responses modulated by benzodiazepines. The effect of CDZ on the GABA response at low dose (a) and at higher dose (b) did not affect the time course of the GABA response as shown in semi-logarithmic plots of the amplitude of the GABA response following the peak response as a function of time.

meter in the Lineweaver-Burke plot (unpublished observations). Modification of coupling between receptor and ionophore is also a possible explanation; an effect on channel duration would be unlikely since this would modify the overall time course of the response, but an effect on unitary channel conductance could be a possible mechanism. Insufficient data is available to allow interpretation of BDZ antagonism of GABA responses.

Thus, this study directly demonstrates that the BDZ have a specific yet dose-dependent effect on GABA-mediated postsynaptic inhibition in mammalian spinal cord neurones, with augmentation obtained at low doses and depression elicited with higher doses. The results do not support BDZ enhancement of glycine-mediated postsynaptic inhibition, as has been suggested previously^{1,2}. Furthermore, the dual effect of BDZ on GABA responses may help to explain why previous studies on different preparations have found opposing results¹³⁻¹⁶. Augmentation of GABA-mediated pre- and postsynaptic inhibition may be the basic feature of its anticonvulsant activity since augmentation of GABA-mediated postsynaptic inhibition by the anticonvulsant phenobarbital has been observed in tissue cultured mammalian neurones^{20,22}, while diphenylhydantoin has been reported to prolong GABA responses in invertebrates²³. The therapeutic role of the inhibition of GABA responses by BDZ is not clear, but it may be responsible for some of the toxic side effects of CDZ and DZ such as ataxia, seizures and tremor. The role of the direct effect of BDZ on neuronal membrane properties seen in these experiments and in sympathetic preganglionic nerves^{11,12} and that of direct BDZ binding to specific receptors derived from rat brain¹⁸ is also uncertain. In the present study, the direct effects were observed at BDZ currents higher than those required for GABA response augmentation. Thus, if GABA response enhancement underlies its anticonvulsant action, the direct effects of BDZ may be relevant only at toxic or non-therapeutic doses.

A study published after submission of our manuscript showed that CDZ selectively augments GABA responses elicited from neurones in chick spinal cord cultures²⁴.

Isolation of specific neurones by affinity methods

THE complex heterogeneity of cell populations in the nervous system severely limits the study of many important questions in neurobiology. Improvement of the current techniques of neuronal cell culture will require methods for selective isolation of neurones belonging to specific functional classes. Present methods include a degree of separation of neurones from non-neuronal cells by physical methods¹⁻³ but these differentiate only on the basis of size or density. The separation of classes of tumour cells and lymphocytes has been accomplished by affinity chromatography using lectins or antibodies against surface antigens⁴⁻⁷. In principle neurone purification could be approached in the same way. Among other surface identities,

Table 2 Induced and constitutive plasmid transfer

Donor strain	Mating medium	
	Arginine + pyruvate	Octopine
B6S3	$\leq 10^{-7}$	19×10^{-2}
B6S3OCC ^c 6	5×10^{-3}	8×10^{-2}
B6S3OCC ^c 8	$\leq 10^{-7}$	13×10^{-2}

Values are transconjugant frequencies amongst the recipients. Recipient and donor strains were grown in arginine plus pyruvate minimal medium (see Table 1) and the crosses were incubated on arginine plus pyruvate minimal medium or octopine minimal medium. The bacterial mixtures were deposited as drops directly on to the mating medium. The crosses were collected, after incubation for 48 h at 25 °C, with a platinum loop and the bacteria were plated on selective minimal medium (rifampicin 100 µg ml⁻¹, octopine 10 mM) after suspension and dilution in water. After incubation for 4 d at 25 °C the Petri dishes were examined and the colonies scored. The higher efficiency of transfer obtained in these crosses as compared with those in Table 1, indicate that these plate matings result in a more efficient conjugation.

opine found in octopine-containing tumours¹⁶, did not induce conjugative activity.

Experiments performed with some strains carrying nopaline Ti plasmids gave analogous results. Some strains such as K14 and T37 can transfer their plasmid in the presence of 10 mM nopaline. For instance, in a cross between strain K14 as the donor and strain GV3102 (a derivative of strain C58C1 that is resistant to 100 µg ml⁻¹ rifampicin and 100 µg ml⁻¹ erythromycin) performed in conditions analogous to those described in Table 1, some transfer of the Ti plasmid (about 10⁻⁴) was detected in the absence of nopaline, whereas 10⁻² of the recipients had acquired a Ti plasmid when the mating was performed in the presence of nopaline. On the other hand, the low frequency of Ti transfer by another nopaline strain, C58, was not enhanced by adding nopaline to the mating mixture.

As the catabolism of nopaline and octopine is coded for by plasmid genes^{7,17} and is also inducible by the same substrates, it was possible that both the catabolic activity and the transfer activity are under the control of a single regulatory system. One would then expect that both processes would respond to the same inducers, and that some regulatory mutations would be found that would interfere with both of these processes. Five natural opines are now known: octopine, nopaline, octopinic acid, lysopine and histopine. We found that the first four of them can induce both processes (ref. 18) and that the fifth is not an inducer for either process (A.P. and J.T., in preparation). To further explore the situation we performed crosses between strain GV3201 as a recipient and strains B6S3, B6S3OCC^c6 and B6S3OCC^c8, the latter two being spontaneous mutants of B6S3, constitutive for octopine catabolism¹⁸. (Strain GV3201 was derived as a rifampicin resistant mutant from strain B9105 (ref. 19) which was shown to be cured of the two plasmids harboured by the parental B91 strain.) The results shown in Table 2 demonstrate that octopine is required for transfer by B6S3 and B6S3OCC^c8, whereas for B6S3OCC^c6 it took place also in the absence of this inducer.

With the nopaline strain T37, whose Ti plasmid transfer is inducible by nopaline, a mutant, T37NOC^c1, could be isolated that is able to grow on octopine as sole carbon and nitrogen source and was shown to be constitutive for both Ti plasmid transfer and nopaline catabolism¹⁸. The capacity of these constitutive mutants to catabolise octopine seems to be due to the ability of the nopaline-degrading enzyme to use octopine as a substrate as well¹⁸. However, other independently isolated derivatives of the same strain, able to utilise both octopine and nopaline as growth substrate, did not transfer their Ti plasmid in the absence of inducer.

Mutants constitutive for transfer were also selected for

directly, by looking for conjugation without induction: high titre mixtures of donor strain GV3110 (C58C1(TiB6S3)) and recipient strain GV3103 (C58C1 Str^rSpc^r) were plated on 0.2% glucose minimal medium. After incubation for 48 h at 28 °C the mixture was inoculated first in a rich medium (0.5% Bacto-beef extract, 0.1% Bacto-yeast extract, 0.5% peptone, 0.5% sucrose in 0.002 M MgSO₄) with 100 µg ml⁻¹ spectinomycin and 100 µg ml⁻¹ streptomycin to eliminate the donor cells and subsequently in octopine minimal medium to enrich for transconjugants. The total transconjugants-recipient population thus obtained was used as donor in a second conjugation without induction with strain GV3102 (C58C1rif^rery^r) as recipient. In this second cross a high level of octopine-utilising transconjugants was obtained. These transconjugants, when used in further crosses, transferred their Ti plasmid at a high frequency (about 10⁻¹) in the absence of octopine and were thus transfer-constitutive.

These results are consistent with the hypothesis of a common regulatory gene controlling two distinct operons, one involved in catabolic activity and the other in plasmid transfer. Our results demonstrate clearly that conjugative activity of the Ti plasmids can be induced by the substrates of some specific enzymes coded for by the Ti plasmids. The types of regulatory mutants that we have been able to obtain thus far are consistent with the idea that a common regulator gene is involved in the control of the activity of two distinct functions—catabolism and transfer.

It is possible that this is but one example of a more general phenomenon. It could be that several bacterial plasmids can be induced to conjugate by a key substance that is a substrate of enzymes coded for by plasmid-borne genes. Some catabolic plasmids and possibly RTF factors might show similar behaviour. Induction of conjugative activity by these conditions that give a selective advantage to plasmid-harboured bacteria would result in efficient spread of the plasmid and thus in a more rapid adaptation of a bacterial population to changes in environmental conditions. Nakazawa and Yokota²⁰ have described a mutant TOL plasmid from *Pseudomonas putida* with increased constitutive levels of metapyrocatechase and increased conjugative activity. The behaviour of this mutant might be explained by the same type of simultaneous regulation of catabolic and transfer functions.

Functional stabilisation of HeLa cell histone messenger RNAs injected into *Xenopus* oocytes by 3'-OH polyadenylation

WE have shown that, when injected into *Xenopus* oocytes, poly (A) free globin messenger RNA is translated for a short period of time and then rapidly degraded¹⁻³, while, under the same conditions, native mRNA shows a marked stability^{1,2,4}. The poly (A) segment itself is responsible for the stability of native globin mRNA, since its readdition to previously de-adenylated mRNA restores the stability of the message⁵. We have shown also that the poly (A) stretch must contain a minimum number of adenylate residues to ensure its protective function⁶. It was interesting to see whether the concept of the stabilisation of eukaryotic mRNAs by 3'-OH polyadenylation is general. This can be done by looking at the effect of the presence of a 3'-OH poly (A) segment on the stability of various mRNAs. Here we study the stability of HeLa cell poly (A)-free histone mRNAs injected into *Xenopus* oocytes, and the effect of 3'-OH polyadenylation on this stability.

An RNA fraction enriched in histone mRNAs (His mRNA) was obtained from polysomes of synchronised HeLa cells in S phase^{7,8}. This RNA preparation, which is not retained on poly (U)-Sepharose on 0.5M KCl at room temperature, directs exclusively the synthesis of human histones in a reticulocyte cell-free protein synthesising system^{7,8}. Fifty oocytes from a single

Xenopus laevis female were injected with 50 µl each of a 750 µg ml⁻¹ aqueous solution of His mRNA. At different times after injection, sets of ten oocytes were incubated in a saline medium containing 1 mCi ml⁻¹ of ³H-lysine (67 Ci mmol⁻¹) at 19 °C for several hours. At the end of the incubation periods, protein samples were prepared from oocytes and analysed by sodium dodecyl sulphate (SDS)-polyacrylamide slab gel electrophoresis¹⁰. Reference ¹⁴C-HeLa cell histones were used as a control. At the end of the electrophoresis, the gels were dried and submitted to fluorography¹¹.

Synthesis of histones H₃, H_{2b}, H_{2a} and H₄ is clearly detected in oocytes injected with the His mRNA fraction (Fig. 1). The synthesis rate of these four proteins is maximal from 5-10 h after microinjection; it then decreases rapidly and becomes almost undetectable after 20 h (Fig. 1). From this result, we conclude that four naturally poly (A)-lacking mRNAs (or mRNAs 'possessing a very short poly (A) segment, since they are not retained on poly (U)-Sepharose) behave, as far as their translation is concerned, in a very similar way to globin mRNA from which the poly (A) segment had been artificially removed¹. It thus seems that a 3'-OH poly (A) segment is required to ensure the stability of several eukaryotic mRNAs.

Fig. 1 Fluorography of a sodium dodecyl sulphate (SDS)-polyacrylamide gel electrophoresis of proteins from oocytes injected with a histone mRNA-enriched fraction from HeLa cells (750 µg ml⁻¹) (His mRNA). Fifty oocytes from a single *Xenopus laevis* female were injected with the His mRNA preparation. At different times after microinjection, sets of ten oocytes were incubated at 19 °C in Barth medium containing 1 mCi ml⁻¹ of ³H-lysine (67 Ci mmol⁻¹). At the end of the incubations, oocytes were washed and homogenised in Tris-glycine 0.05M, pH 8.9. Cell debris and yolk platelets were removed by low speed centrifugation and the supernatant was made 2% in SDS and 5% in mercaptoethanol. Aliquots of the supernatants containing 400,000 dpm of trichloroacetic acid precipitable counts were analysed by electrophoresis on a 15% polyacrylamide slab gel¹⁰. After staining and destaining, gels were treated for and submitted to fluorography¹¹. a, Reference ¹⁴C HeLa cells histones; b, proteins from control oocytes injected with water; c-f, proteins from oocytes injected with His mRNA. Incubation periods: b, c, 0-5 h; d, 5-10 h; e, 10-20 h; f, 20-48 h.

Fig. 2 Fluorography of a SDS-polyacrylamide gel electrophoresis of proteins from oocytes injected with either a native His mRNA fraction from HeLa cells (channels b-d) or this His mRNA fraction previously polyadenylated (channels e-g). Both RNA preparations have been injected at 750 µg ml⁻¹. Eighty oocytes from a single *Xenopus laevis* female were injected either with native His mRNA or with polyadenylated His mRNA (40 oocytes with each preparation). At different times after microinjection, sets of ten oocytes from each batch of cells were incubated at 19 °C in Barth medium containing 1 mCi ml⁻¹ of ³H-lysine (67 Ci mmol⁻¹). At the end of the incubations, oocytes were processed as described in Fig. 1 for gel electrophoresis. a, reference ¹⁴C HeLa cells histones; oocytes injected with native His mRNA; e-g, proteins from oocytes injected with polyadenylated His mRNA. Incubation periods: b, e, 0-7 h; c, f, 7-19 h; d, g, 43-60 h.

To test this assumption, a poly (A) stretch containing 40 to 50 adenylate residues was added to the 3'-OH end of the His mRNA fraction using an ATP : RNA adenylyltransferase from *Escherichia coli*, and the functional stability of this polyadenylated mRNA was tested after microinjection into oocytes. The polyadenylated His mRNA fraction and control poly (A)-free His mRNA were thus injected at a concentration of 750 µg ml⁻¹ into two sets of 50 oocytes from the same *Xenopus* female. At different times after microinjection, batches containing 10 oocytes were incubated in a saline medium containing 1 mCi ml⁻¹ of ³H-lysine (67 Ci mmol⁻¹) at 19 °C for several hours. At the end of the incubation periods, protein samples were prepared and analysed by SDS-polyacrylamide slab gel electrophoresis. At the end of the electrophoresis, the gels were dried and submitted to fluorography¹¹.

Fig. 1 *a*, Chick embryo sympathetic ganglion neurons bound to α BT-Sephadex 6MB beads. $\times 120$. *b*, The same beads do not bind HeLa cells significantly. α BT-derivatised beads were synthesised as follows; 100 μ l of *p*-aminobenzoylhexylamino Sephadex 6MB¹² beads were diazotised in 0.1 M sodium nitrite in 0.1 M HCl-0.2 M NaCl for 10 min at 0°C. The beads were washed with ice-cold PBS (after excess nitrous acid had been destroyed with 0.1 M sulphamic acid) and added immediately to a solution of approximately 1 mg of α BT in 0.5 ml of 0.05 M borax pH 8. Reaction was allowed to proceed overnight at 4°C and the resulting dark-yellow beads were washed extensively with PBS. The amount of toxin covalently attached to the beads was estimated by measuring the A_{280} of the supernatant at the end of the reaction. Typically a concentration of α BT on the beads of approximately 1 mM was achieved.

neurons have neurotransmitter receptors which provide one basis for functional classification and potentially provide targets for affinity probes of high specificity. As a model system we chose the chick embryo sympathetic ganglion neurons which are known to possess high numbers of the nicotinic type of acetylcholine (ACh) receptor³. These cells also possess high numbers of receptors for α -bungarotoxin

(α BT)⁹. We report here the successful separation by affinity chromatography of the principal neurones from sympathetic ganglia using α BT as a probe.

α BT was attached to Sephadex 6MB by reacting the toxin in borax buffer pH 8 with diazotised *p*-aminobenzoylhexylamino Sephadex 6MB (ref. 10). This procedure results in the formation of an azo linkage with one or other of the two histidine residues (positions 4 and 67)¹¹. In view of the structural similarity between types I and II neurotoxins¹¹ and the fact that the extra disulphide bond in type II toxins is not essential for activity¹² it is reasonable to assume a conformation for α BT similar to that recently determined for erabutoxin b by X-ray crystallography¹³. In this conformation the two histidines in α BT are well removed from the active site and their modification is unlikely to affect the biological activity. Indeed the derivatised beads bind chick embryo sympathetic ganglion neurones in preference to other cell types (Fig. 1).

Sympathetic ganglion cells were prepared from 19-d chick embryos as previously described¹⁴. At this age the neurones have approximately 2×10^5 α BT receptors per cell⁹. After trypsinisation (0.025%) the cells were dissociated in Puck's saline G containing 2 mg ml⁻¹ bovine serum albumin, 20 μ g ml⁻¹ deoxyribonuclease (DNase) and 10 units ml⁻¹ nerve growth factor (NGF)¹⁵; this will be referred to as medium A. The cells were then filtered through nylon gauze (pore size < 50 μ m), centrifuged and resuspended at 1×10^6 cells ml⁻¹ in medium A. The α BT-derivatised macrobeads were held in the bottom of a small glass water-jacketed column by a piece of nylon gauze held in place by a tightly fitting Teflon ring. The assembled column without beads was autoclaved and all manipulations were carried out in a sterile laminar flow cabinet. The beads were extensively washed with sterile phosphate-buffered saline (Ca²⁺ Mg²⁺-free Dulbecco's PBS), then medium A. The flow rate was adjusted to 1–2 ml h⁻¹ and the cell suspension loaded. It was important to maintain a temperature of 0–4°C throughout the isolation procedure for optimal viability of the neurones. The beads were washed until very few non-neuronal cells were present in the eluate. After further washing with PBS containing DNase (4 μ g ml⁻¹) and subsequently with PBS containing DNase and 0.1% trypsin, the column was clamped off, the temperature raised to 37°C and incubation allowed for 2–3 min. Foetal calf serum (FCS) was then added and the cells eluted with about 10 ml of F15 medium (GIBCO) containing 5% FCS (growth medium) into a sterile centrifuge tube. The cells were centrifuged, resuspended in 1 ml growth medium containing 10 U ml⁻¹ NGF and cultured.

Fig. 2 Purification of sympathetic ganglion neurones. *a*, Original cell suspension containing approximately 10% principal ganglion neurones. *b*, Eluate from the affinity column during washing. Essentially all non-neuronal elements. *c*, Final suspension of purified neurones after removal from column by trypsin (0.1%). Phase contrast $\times 370$.

Fig. 3 Phase contrast photomicrographs of cultured sympathetic ganglion neurones: parallel purified and nonpurified cultures. $\times 328$. *a*, Purified neurones, 1 d *in vitro*. *b*, Purified neurones, 6 d *in vitro*. *c*, Non-purified neurones, 1 d *in vitro*. *d*, Non-purified neurones, 6 d *in vitro*. Comparison of (*b*) and (*d*) shows that the purified neurones are relatively free of fibroblasts while non-purified cultures are virtually overgrown by non-neuronal elements. The cells were plated into 33-mm tissue culture dishes (Kayline Plastics). For isolated neurones, plates were coated with tail collagen¹⁷. A collagen substrate is not necessary in the presence of non-neuronal cells. Cultures were maintained in a humidified atmosphere of 5% CO₂-95% air and the medium was changed every second day.

Figure 2 shows the cell suspension at different stages during the purification. The original cell suspension contained about 10% principal neurones and the final cell suspension > 95% neurones. Thus we have achieved a purification of the neurones of 9 to 10 fold. By the concomitant use of differential plating¹⁶ and the use of mitotic inhibitors for a short period after plating, the few remaining non-neuronal cells could be eliminated, giving 100% purity. Alternatively, nonspecific binding may be eliminated by more extensive washing or possibly by the inclusion of a small inert charged molecule to eliminate charge interactions.

The isolated neurones were viable after 6–8 h on the column. Cultured, purified neurones are compared with parallel non-purified cultures in Fig. 3. After the same period *in vitro* those neurones which had gone through the affinity column were still free of non-neuronal cells.

The functional viability of the isolated neurones was examined by electrophysiological measurements (Fig. 4). The neurones responded in an all-or-none fashion to electrical stimulation and responded to iontophoretically-applied acetylcholine, showing desensitisation on repeated application. Autoradiography showed that essentially all the isolated neurones bind [¹²⁵I]- α -bungarotoxin (data not shown).

Thus, we have been able to obtain essentially pure, viable and electrically active neurones. The same results were obtained using as an affinity probe the α -neurotoxin from the venom of *Naja nigricollis* purified by CM cellulose chromatography. The availability of suitable specific immobilised ligands for in-

vestigation *in vitro* of important questions such as synaptic specificity, neuronal-non-neuronal cell interactions and the behaviour of particular neurone populations in certain disease states. We are investigating the possibility of using small molecule affinity probes and applying our isolation procedure to neurones from the brain.

We thank John Leah for carrying out the electrophysiological measurements. This work was supported by the Australian Research Grants Committee.

Paired helical filaments of the Alzheimer type in cultured neurones

ALZHEIMER'S disease, a common progressive dementia of later life, is associated with several histopathological changes. Although one of these pathological changes, neuritic plaques with amyloid cores, has been reproduced in brain of mice following inoculation with scrapie agent^{1,2}, Alzheimer-type neurofibrillary degeneration has not yet been reproduced in the laboratory. This unique form of human neurofibrillary degeneration is composed of arrays of paired 100-Å diameter filaments twisted into a helical configuration with a period of approximately 800 Å (refs 3, 4). We present here evidence that paired helical filaments

morphologically closely resembling those found in the human disease are induced in cultured human foetal cerebral cortical neurones after exposure to an extract prepared from Alzheimer-affected brain.

Explanted fragments (0.5 mm^3) of cerebral cortex derived from two human foetuses of approximately 12–14 weeks gestation were used in this initial study. Explant cultures were maintained on collagen-coated coverslips⁵ in a medium composed of 35% Simm's balanced salt solution, 40% heat-inactivated human cord serum and 25% medium 199 (GIBCO), with 600 mg% glucose (final concentration). The coverslips with cultures were placed into plastic Petri dishes (Falcon) and incubated at 36°C in a water-saturated atmosphere of 95% air and 5% CO_2 . The culture medium was changed twice weekly. A saline extract was prepared from cerebral cortex of a patient who died aged 63 after a 6-yr history of progressive intellectual deterioration and whose brain exhibited widespread neurofibrillary degeneration and senile plaques typical of Alzheimer's disease. The brain was removed 12 h post-mortem and stored frozen at -90°C . Four months later a cortical sample of approximately 2 cm^3 was removed from the tip of the temporal lobe, thawed and homogenised in an equal volume of sterile physiological saline at 4°C in a Potter-Elvehjem homogeniser. The homogenate was spun in a bench-top centrifuge at 1,500 r.p.m., the pellet discarded, and the cell-free supernatant passed through a Millipore filter of 4,500 Å pore size. Ultrastructural examination of the filtrate by standard positive and negative staining methods did not reveal fragments of paired helical filaments. The filtrate did, however, contain fragments of microtubules, ranging in length from 600 to 2,300 Å and small membrane fragments. No particles

exhibiting viral morphology were encountered. The human, foetal cerebral explants were exposed to an approximately 5% solution of the Alzheimer brain extract for the first 6 d in culture. After this initial exposure, feeding was carried out with pure culture medium. The cultures were fixed at various intervals after inoculation with 3.5% glutaraldehyde in phosphate buffer.

Detailed ultrastructural examination of cultures fixed after 4, 8 and 11 d of incubation revealed no paired helical filaments and the morphological characteristics of the cells were identical to those in control cultures (Fig. 1). However, after 14 d incubation, occasional paired helical filaments were observed, and after 35 d of incubation, paired helical filaments were found in many cell processes. Approximately 3% of all cell processes ($n = 491$) at 35 d incubation contained one or more paired helical filaments. Synaptic contacts established that many of the processes containing these paired filaments were definitely of neuronal origin. Many examples of paired helical filaments occurred in cells in which the cytoplasm seemed swollen and the density of organelles was reduced. The plasma membranes of affected cells were intact, although microtubules seemed fragmented and mitochondria were often dense. Many of the paired helical filaments seemed to be assembled from separate, morphologically normal appearing neurofilaments (Fig. 2d). The average diameter of the individual filaments composing the helical structures in the cultured cells was 95 Å (s.d. 16 Å , $n = 12$) and the average width of pairs was 289 Å (s.d. 45 Å , $n = 13$). This is to be compared with the

paired helical filament in Alzheimer's disease in which individual filaments have an average diameter of 95 Å (s.d. 17 Å, $n = 13$) and a mean overall width of 241 Å (s.d. 55, $n = 9$). The paired, helical filament of Alzheimer's disease usually exhibits nodes with a mean period of approximately 800 Å, although internode distances of up to 1,000 Å are not uncommon⁶. In the cultured foetal cells, the internode period ranged from 800 to 1,600 Å, and a mean value of 846 Å (s.d. 133 Å) was measured on several typical paired helical filaments displaying up to 10 nodes (Fig. 3c). In contrast to the neurofibrillary tangle of Alzheimer's disease, in which dense aggregates of paired helical filaments occur, the number of paired helical filaments per cultured cell was small, and dense aggregates were not observed. Typically, the paired helical structures induced in culture did not display electron dense material along the filaments and seemed more distinct than those observed in Alzheimer's disease.

Electron microscopic examination of over 500 human cerebral cultures not exposed to the Alzheimer extract has never revealed paired helical filaments, although these cultures were exposed to a variety of toxic agents, including aluminium⁷, osmotic stress, fungi and bacteria. Moreover, over 500 brain explants from goldfish⁸, foetal rabbits and foetal mice similarly exposed to various toxic agents never exhibited paired helical filaments.

The observations described here suggest at least three possibilities. The Alzheimer donor brain may have contained metabolic products, possibly associated with the degeneration, which are capable of assembling neurofilaments into paired, helical structures. Such molecules may be postulated to have high affinities for specific sites on normal neurofilaments, resulting in their cross bonding and twisting into a helical configuration. Alternatively, the assembly factor may arise from a viral product present in brain affected by Alzheimer's disease, or, a viral-like agent may have been transferred to the cultured cells and the

paired helical filaments may have resulted from the replication of a transmissible agent in the cultured human brain cells. Although several morphologically distinct types of viral particles were observed in the cultures exposed to the extract from Alzheimer-affected brain their relationship to the paired helical filaments is not yet known.

This research was supported by the Ontario Mental Health Foundation. We thank A. Rodriguez for technical support and Dr J. Deck, Department of Pathology.

Note added in proof: Since the introduction of Alzheimer material into the incubator, repetition of the above experiments has revealed the presence of an occasional control explant with paired helical filaments. Since all other variables have remained unchanged, we interpret this as support for the possibility that paired helical filaments are a response of human neurones to an infectious agent.

Identification of the binding protein which may be the target of penicillin action in *Bacillus megaterium*

PENICILLINS and cephalosporins (β -lactam antibiotics) are believed to kill bacteria by inhibiting reactions involved in the final stages of cell wall assembly¹. It is widely assumed that inhibition of a transpeptidase involved in the insertion of nascent peptidoglycan strands into the cell wall directly leads to cell death. One approach to the study of the lethal action of penicillin has involved the investigation of penicillin-binding proteins (PBPs) which, with few exceptions, are located exclusively in the cytoplasmic membrane of bacteria^{2–4}. PBPs form covalent complexes with benzyl-(¹⁴C)-penicillin, and can be detected by fluorography after sodium dodecyl sulphate (SDS) polyacrylamide gel electrophoresis. All species of bacteria examined contain multiple PBPs. We have shown that the isolated membranes of *Bacillus megaterium* contain five proteins which bind benzylpenicillin covalently and we have measured their relative affinities for the antibiotic⁴. However, the accessibility of the PBPs and their affinities for penicillin may be different in whole cells, and to identify the PBP which represents the lethal target for benzylpenicillin, it is necessary to investigate the binding of the antibiotic to the PBPs of whole cells. We report here that only one of the five PBPs in *B. megaterium* reacts with benzylpenicillin to any significant extent at concentrations just sufficient to kill the cells, and that the characteristics of the inhibition and of the breakdown of the PBP–penicillin complex are consistent with its being the protein which catalyses transpeptidation.

It is difficult to run quantities of whole cell protein sufficient to reveal the PBPs by fluorography in a reasonable time, without overloading the polyacrylamide gel. Because all the PBPs of *B. megaterium* are located in the membrane, it was possible to carry out the experiment by incubating intact cells with penicillin followed by preparation of the membrane fraction and examination of the PBPs. A preliminary investigation showed that release of bound penicillin from the PBPs was slow, with PBPs 1 and 5 having the shortest half-lives of breakdown at

Fig. 3 Electron micrographs comparing paired, helical filaments from an Alzheimer affected brain (a, b) to a paired, helical filament in a cultured foetal brain cell; 35-d *in vitro*. In (a), (c), scale bar 0.1 μ m; b, 0.05 μ m.

Fig. 1 Fluorogram demonstrating the sensitivity of membrane-bound penicillin-binding proteins in whole cells of *Bacillus megaterium*. 10-ml cultures of *B. megaterium* KM growing exponentially in a complex medium were treated with a range of concentrations of benzyl- ^{14}C -penicillin (51 Ci mol^{-1}) when the cell density had reached $0.3 \text{ mg dry weight ml}^{-1}$. After 5 min at 37°C , 10 mM nonradioactive benzylpenicillin was added, the cells were collected rapidly by centrifugation at 4°C ($27,000g$, 1 min), washed in ice-cold 25 mM Tris-HCl, 5 mM MgCl_2 , $\text{pH } 7.2$, resuspended in 0.3 ml of the same buffer containing lysozyme ($250 \text{ } \mu\text{g ml}^{-1}$) and DNA-ase ($5 \text{ } \mu\text{g ml}^{-1}$), and incubated at 37°C until lysis was complete (5 min). The membranes were collected by centrifugation at $40,000g$ for 20 min and dissolved by boiling for 1 min in $50 \text{ } \mu\text{l}$ buffer containing 10% glycerol, 1% SDS, 1% 2-mercaptoethanol and 0.002% bromophenol blue in 10 mM Tris-HCl $\text{pH } 7.2$. The membrane proteins were separated by electrophoresis on a 10% polyacrylamide slab gel containing SDS (ref. 5), and the penicillin-binding proteins (PBPs 1-5, numbered in order of decreasing molecular weight, ref. 4) revealed by fluorography 6,7 . The following concentrations of benzyl- ^{14}C -penicillin were employed ($\mu\text{g ml}^{-1}$): a, 0.003; b, 0.006; c, 0.01; d, 0.03; e, 0.06; f, 0.1; g, 0.3; h, 0.6; i, 1.0; j, 5.0.

37°C (15–40 min). The conditions of membrane isolation (5 min at 37°C with lysozyme, followed by the remainder of the manipulations being carried out at 4°C (approximately 45 min)) were such that they would not result in significant breakdown of PBP-penicillin complexes.

Whole cells of *B. megaterium* were incubated with a range of concentrations of benzyl- ^{14}C -penicillin, collected, washed, lysed by treatment with lysozyme and the protoplast membranes obtained by centrifugation. The proteins of the membrane were fractionated by SDS-polyacrylamide slab-gel electrophoresis 5 and the PBPs detected by fluorography 6,7 . This enabled the affinities of the PBPs for benzylpenicillin in whole cells to be determined. The relative affinities of the PBPs were the same as had been found previously when isolated membranes were treated with benzylpenicillin 4 , although the absolute concentrations of the antibiotic resulting in 50% saturation of the PBPs were lower than when membranes were used. The PBPs are likely to be more accessible in membranes than in whole cells, and this suggests that the amount of penicillin available to react with the PBPs of membranes may have been a limiting factor at the lower concentrations of the antibiotic. This possibility will be considered elsewhere. It is clear from the results in Fig. 1 that PBP 1 has the highest affinity for benzylpenicillin, but this information alone is insufficient to implicate this protein as the lethal target of penicillin. It is necessary to investigate which PBPs bind penicillin when growing cells are labelled at concentrations of the antibiotic which are just sufficient to interfere with growth or cause cell death. The growth of *B. megaterium* as measured by increase in turbidity was inhibited by 50% at a concentration of $0.03 \text{ } \mu\text{g}$ benzylpenicillin per ml; at this concentration, the saturation of PBPs 1–5 in whole cells was 75, 12, 8, 4 and 0% respectively. Over a long period, the inhibition of an essential enzyme by as little as 10% might be sufficient to impair growth, but in this short term growth experiment over a period of three generations,

it seems unlikely that such a degree of inhibition (of PBPs 2 and 3) would account for the immediate inhibition of growth. We therefore conclude that PBP 1 is most likely to be the lethal target of penicillin.

At the minimum growth inhibitory concentration of $0.03 \text{ } \mu\text{g ml}^{-1}$, more than 80% of the total radioactivity bound to the PBPs was present in PBP 1, with approximately 5% on PBPs 2, 3 and 4 (Fig. 2). As the concentration of benzylpenicillin was lowered further to that which inhibited the growth of cells from a small inoculum ($10^6 \text{ cells ml}^{-1}$) in liquid medium ($0.01 \text{ } \mu\text{g ml}^{-1}$), or that which inhibited the growth of single cells on agar ($0.006 \text{ } \mu\text{g ml}^{-1}$), no radioactivity was found associated with PBPs 2–5, while appreciable binding of benzyl- ^{14}C -penicillin to the PBP 1 of intact cells was still demonstrable (Fig. 1). This is further indication that PBP 1 is of prime importance in the interaction of benzylpenicillin with whole cells of *B. megaterium*.

It is possible that benzylpenicillin interacts non-covalently with the killing site, or forms a covalent complex which breaks down so rapidly before or during SDS gel electrophoresis that it is not subsequently detected as a PBP. Under these circumstances it would obviously not be possible to correlate the killing site of penicillin with a particular PBP. The characteristics of the interaction of benzylpenicillin with PBP 1, however, are identical to those of the inhibition of the natural peptidoglycan transpeptidation reaction which is catalysed by wall/membrane preparations of *B. megaterium*. This transpeptidation reaction is inhibited by 50% at $0.1 \text{ } \mu\text{g}$ benzylpenicillin per ml (ref. 8), a concentration which results in approximately 50% saturation of PBP 1 in isolated membranes. Preliminary studies on the interactions of benzylpenicillin with the natural transpeptidation system suggest that a covalent complex is formed, and subsequently breaks down, with a half life of 50–60 min at 23°C . PBP 1 interacts with benzylpenicillin to form a covalent complex which also breaks down with a half life of 60 min at 23°C , and this is consistent with the hypothesis that the natural transpeptidation reaction which represents the lethal target of penicillin action is catalysed by PBP 1. Proof of the hypothesis will have to await the demonstration that purified PBP 1 can catalyse a transpeptidation reaction. PBP 1 has been solubilised and purified almost to

Fig. 2 Binding of benzyl- ^{14}C -penicillin to the proteins of whole cells of *Bacillus megaterium*. The degree of blackening of the X-ray film resulting from the ^{14}C -penicillin-protein complexes was determined by scanning the fluorogram shown in Fig. 1 with a Joyce-Loebl micro-densitometer and determining the areas of the peaks thus obtained by weighing. The amount of radioactivity bound to the individual PBPs at the various concentrations of benzyl- ^{14}C -penicillin is expressed as % of the total radioactivity bound at that concentration. The arrow denotes the concentration of benzylpenicillin which just inhibits growth of the organism over a period of three generations (minimum growth inhibitory concentration). ●, PBP 1; △, PBP 2; □, PBP 3; ○, PBP 4.

homogeneity but no enzymic activity in peptidoglycan biosynthesis has yet been ascribed to it⁴. It will be necessary to devise natural model transpeptidation reactions that can be catalysed by the penicillin-sensitive enzymes involved in the terminal stages of peptidoglycan biosynthesis. Such reactions exist for *Salmonella typhimurium*, in which it has been shown that PBP 4 and probably PBP 1 catalyse transpeptidation⁹, and also for *Escherichia coli*¹⁰, but all attempts to develop similar systems for the Gram-positive bacilli have been unsuccessful.

Substrate induction of conjugative activity of *Agrobacterium tumefaciens* Ti plasmids

CONJUGATIVE plasmids of bacteria are extrachromosomal genetic elements able to bring about DNA transfer by conjugation. The best-studied system is that of F-like plasmids in *Escherichia coli*, where at least 12 genes are involved¹. Expression of the transfer system in this case is subject to negative control^{2,3}. We report here that the newly discovered conjugative activity of Ti plasmids is inducible by specific amino acid derivatives that are also the substrates for plasmid-coded catabolic enzymes. This finding further extends the analogy between the regulation of the lactose operon and of transfer functions.

The Ti plasmids confer oncogenicity to *Agrobacterium tumefaciens* strains responsible for the crown-gall disease of plants^{4–7}. The plasmids apparently fall into three classes, between which there is only a limited degree of homology^{7–11}. First, octopine Ti plasmids trigger octopine (N-2-(D-1-carboxyethyl)-L-arginine) synthesis in transformed plant cells. Such plasmids also confer to these bacteria the ability to utilise octopine as sole carbon and/or nitrogen sources. All the octopine Ti plasmids isolated thus far from different strains seem to be nearly, if not completely, identical^{7–11}. Second, nopaline Ti plasmids trigger nopaline (N-2-(D-1-3-dicarboxypropyl)-L-arginine) synthesis in transformed plant cells. They also confer to their bacterial hosts the ability to use nopaline as sole carbon and/or nitrogen sources. The nopaline Ti plasmids isolated from different strains show a wider range of relatedness^{7–11}. The third kind of Ti plasmids has, so far, no recognised property other than oncogenicity.

We have shown that the Ti plasmids are conjugative^{12,13} as they can be efficiently transferred to non-oncogenic recipient strains of *Agrobacterium* in certain conditions. In our previous work we made use of the fact that these plasmids are catabolic plasmids to select for transconjugants. We noted that plasmid transfer could only be observed if the crosses had been performed in the presence of the arginine derivative—an 'opine'—that is specific for the type of Ti plasmid used in the transfer experiment. One possible interpretation for this result was that octopine or nopaline

induces the conjugative activity of octopine Ti plasmids and nopaline Ti plasmids respectively. However, as the mixed donor and recipient cultures had been inoculated on media in which the opine was either the source of nitrogen or the source of both carbon and nitrogen, some selection must also have been operating to favour transconjugants relative to recipient cells. The experiments described here were designed to distinguish between the models of induction of transfer and selection of transconjugants.

The purpose of a first series of experiments was to determine whether incubation of the donor cells in an opine-containing medium before mixing with the receptor resulted in the induction of conjugative activity. Octopine was found to induce conjugative activity of the Ti plasmid of strain B6S3 (Table 1). Crosses performed with donors that had been previously cultured on octopine yielded transconjugants whereas donors cultivated on arginine and pyruvate (the immediate products of octopine catabolism¹⁴) did not transfer their plasmid in the absence of octopine. When the filters with the mating mixture were incubated on arginine and pyruvate medium, relatively low frequencies of transconjugants were obtained; however, when octopine was used instead of arginine and pyruvate in the mating medium, high frequencies of transconjugants were observed. Their increased frequency is probably due to the duration of the incubation of the mating mixture (48 h) in the presence of octopine; this probably resulted in an increased number of donors transferring their Ti plasmid and also an enrichment of transconjugants relative to the recipients, since octopine was the sole carbon and nitrogen source in the mating medium. Two other opines, lysopine and octopinic acid, which are synthesised concomitantly with octopine in crown-gall cells¹⁵ and can also be utilised as both carbon and nitrogen source by *Agrobacterium* strains harbouring an octopine Ti plasmid, also induce conjugation, but to a lesser degree than octopine. In contrast histopine, a novel

Table 1 Induction of plasmid transfer

Mating medium	Preculture medium (C and N sources)	
	Arginine + pyruvate*	Octopine
Arginine + pyruvate	$\leq 10^{-7}$	7×10^{-5}
Octopine	2×10^{-3}	8×10^{-3}

Values shown represent transconjugant frequencies amongst the recipients. The donor strain B6S3, which carries an octopine Ti plasmid, was crossed with the recipient strain C58Cl. Single colony isolates of B6S3 were grown in liquid minimal medium containing KH_2PO_4 $8.0 \times 10^{-2}\text{M}$, $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ $6.5 \times 10^{-4}\text{M}$, $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$ $7.0 \times 10^{-5}\text{M}$, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ $1.7 \times 10^{-6}\text{M}$, $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ $1.0 \times 10^{-5}\text{M}$, pH adjusted to 7.0 with KOH 6N, supplemented with either octopine 10 mM or arginine 10 mM plus pyruvate 10 mM as carbon and nitrogen sources. The cultures, in exponential phase of growth, were mixed in a ratio of 10:1 with recipient C58Cl cells exponentially growing on arginine plus pyruvate minimal medium. The bacterial mixtures were diluted to A_{600} of 0.2 and 5-ml samples were forced through Millipore filters (pore size 0.45 μm). The filters were incubated for 48 h at 25 °C on agar (1.5%) minimal medium (mating medium) supplemented with 10 mM octopine, or arginine plus pyruvate. The filters were introduced into test tubes containing 5 ml of sterile water and the bacteria on the filters were suspended by vortex action. These suspensions were then diluted and plated on a selective medium containing octopine 10 mM, rifampicin 50 $\mu\text{g ml}^{-1}$ and streptomycin 500 $\mu\text{g ml}^{-1}$. This medium allows only a very limited growth of the recipients which are resistant to the antibiotics but cannot use octopine as a growth substrate. The donors are eliminated by the action of the antibiotics. The transconjugants were selected for by their capacity to utilise octopine and develop into normal colonies. The plates were scored after incubation for 8 d at 25 °C.

* Replacement of arginine plus pyruvate by glucose (2 g l^{-1}) gave almost identical results.

Fig. 3 Fluorography of SDS-polyacrylamide gel electrophoresis of proteins from oocytes injected with native His mRNA (500 $\mu\text{g ml}^{-1}$) supplemented with commercial poly (A) (500 $\mu\text{g ml}^{-1}$). Fifty oocytes from a single *Xenopus laevis* female were injected with native His mRNA supplemented with commercial poly (A). At different times after microinjection, sets of ten oocytes were incubated at 19 °C in Barth medium containing 1 mCi ml^{-1} of ^3H lysine (67 Ci mmol^{-1}). At the end of the incubations, oocytes were processed as described at Fig. 1 for gel electrophoresis. *a-d*, proteins from oocytes injected with native His mRNA + commercial poly (A); *e, f*, proteins from control oocytes. Incubation periods; *a, e*, 0–4 h, *b*, 4–20 h, *c*, 20–48 h, *d, f*, 48–60 h.

In complete agreement with the previous experiment, it was found that, in oocytes injected with native His mRNA, the rate of synthesis of H_3 , H_{2a} , H_{2b} and H_4 histones increases during the first 7 h, then decreases during the 7–19 h incubation period and becomes finally hardly detectable 43 h after microinjection (Fig. 2). In the case of polyadenylated His mRNA, however, the synthesis rate of the four histones increases up to 19 h and is still very high more than 43 h after microinjection (Fig. 2). One may thus conclude that the addition of a poly (A) segment at the 3'-OH end of the four naturally poly (A)-free mRNAs coding for H_3 , H_{2a} , H_{2b} and H_4 histones functionally stabilises these messages.

We wanted to see whether poly (A) molecules injected at the same time as His mRNA would have the same effect on the stability of histone mRNAs as terminal polyadenylation. So, we compared, in the same kind of experiment as those described above, the functional stability of His mRNA injected alone (at 500 $\mu\text{g ml}^{-1}$) or with commercial poly (A) (100–200 nucleotides long) at 500 $\mu\text{g ml}^{-1}$. Figure 3 shows that the presence of poly (A) injected at the same time as the His mRNA fraction does not increase the functional stability of histone mRNAs, although the concentration of poly (A) is approximately ten times higher than when linked to the 3'-OH end of the message molecules, as in the preceding experiment. It thus seems that, in oocytes, the 3'-OH poly (A) segment does not protect the mRNA molecule simply by competitive inhibition of ribonuclease activity as might be inferred by the work of others in *in vitro* experiments¹³. The protection mechanism must be more specific, and we have indeed shown that the degradation of a poly (A)-lacking mRNA is associated with its translation³.

We suggest that the presence of a poly (A) stretch long enough at the 3'-OH end of four different histone mRNAs ensures their functional stability when injected into *Xenopus* oocytes. These results extend our previous conclusion about the stabilising role of poly (A) obtained from experiments using native and deadenylated globin mRNA^{1–3,5,6} (for review see ref. 14). Preliminary results from experiments using sea urchin embryo histone mRNAs confirm our conclusion.

Role of the G segment in the growth of phage Mu

USING the single-burst technique we have been able to show that close to one-half of the cells in a lysogenic culture of phage Mu yield no viable phage after induction. Our experiments were prompted by an intriguing observation concerning the G segment of Mu, a region of 3,000 base pairs found in either orientation in both mature phages and prophages^{1,2}; it is thought that G inversions are mediated by inverted repeats of approximately 50 base pairs known to be located at the two ends of G (ref. 3). It was observed that progeny phage derived from the induction of lysogenic cultures contain approximately equal numbers of particles with the G segment in either orientation, but virtually all progeny phage derived from lytic cycles of infection have their G segment in one particular orientation⁴.

The simplest proposal to explain this behaviour is based on the following assumptions⁵: (1) inversion of the G segment occurs only in the prophage state. (2) On induction individual lysogenic cells produce bursts in which all phages have the G segment in the same orientation as the parental prophage. (3) Phages with the G segment in one orientation, say G(+), are viable in lytic infection, with the G(–) orientation they are non-viable. (4) The frequency of inversion of G during growth of a Mu lysogen is such that in any culture of 10^8 cells (the minimum required for electron microscope experiments) the G(+)/G(–) ratio is close to 1.

These assumptions lead directly to the prediction that only one-half of the individual cells in a lysogenic Mu culture yield viable phage after induction.

Table 1 Comparison between tubes tested immediately after inoculation

Tubes per set	Tubes containing bacteria (set 1)	Tubes yielding viable phage (set 2)	Expected tubes* from theory yielding viable phage
132	32	20	17
156	62	30	35

The bacterial strain used was a derivative of the *Escherichia coli* K12 strain CSH55 (ref. 10), CSH55Mu^R/F⁺pro⁺lac::Muets62. To test for the presence of viable phage 0.25 ml of a stationary culture of the indicator bacteria CR63 was added to each tube and these were then incubated overnight at 32 °C. Next day samples from the tubes were spotted onto plates seeded with CR63, and these plates incubated overnight at 37 °C.

*This number makes allowance for the fraction of tubes receiving more than one cell at the multiplicities used.

We set out to test this prediction in experiments reported here, using an adaptation of the classical 'single-burst' experiment of Burnet⁶. In the first experiments a culture of of a mono-lysogenic bacterial strain containing the heat-inducible prophage Muets62 was grown in broth at 32 °C to 10⁸ cells ml⁻¹. The culture was then diluted appropriately and aliquots distributed amongst two sets of broth-containing tubes with such a multiplicity of bacteria per tube (0.2–0.5) that the majority of tubes which received bacteria were inoculated with a single cell. One set of tubes was then incubated overnight at 32 °C and examined next day to determine the number of tubes containing bacteria; the second set was immediately placed at 43 °C for 60 min (conditions which provoke induction and lysis) and each tube then tested for the presence of viable phage.

Table 1 represents the results of two experiments of this type. The ratio between the numbers of tubes yielding viable phage in one set of tubes and those containing bacteria in the parallel set is close to that predicted by the model. However, a drawback of this kind of experiment is that the numbers involved in the comparison between the two sets of tubes are inevitably small and so possible statistical fluctuations are considerable. To obtain more compelling evidence concerning the basic assumption that the induction of individual lysogenic cells often does not yield viable Mu phage, we modified the experimental procedure to obviate the statistical criticism of the previous results.

The starting point of the modified experiments was similar to the previous ones, but the sets of tubes were now left after inoculation at 32 °C before testing, to allow clones of bacteria to develop in those tubes receiving cells. After various periods of time a set of tubes was removed from 32 °C and the contents of each tube (1 ml) split into two equal volumes. One of these was then assayed to determine the number of cells it contained; the other was induced and then tested for the presence of viable phage.

Table 2 Tests of individual clones for viable phage

Tubes per set	156	
Time of incubation (h)	3	4
No. of tubes containing clones	64	60
Average clone size (no. of bacteria)	28	58
Clones yielding viable phage	46	48
Clones yielding no viable phage	18	12
Fraction of clones yielding no viable phage	0.28	0.20

Bacterial assays were performed by adding 0.5 ml of 1.2% molten Difco agar to each 0.5 ml volume to be tested, shaking the tubes, and then incubating them for 2 d at 30 °C. At this stage spherical colonies could easily be seen and counted. Testing of the other 0.5 ml volumes for viable phage was carried out as in the previous experiment.

Table 2 presents the result of an experiment of this type in which the clones were allowed to develop for 3 or 4 h before testing, at which times they contained an average of 28 and 58 cells respectively. It can be seen that even after 4 h growth there were 12 tubes which, after division, yielded bacteria but no viable phage. The chance that this lack of viable phage was due to the absence of bacteria in the induced volumes is negligible, as in 10 of the 12 tubes the bacterial assays on equivalent volumes were greater than 20. This evidence therefore shows quite clearly that some lysogenic Mu cells yield no viable phage on induction.

Also from Table 2 it can be seen that the fraction of clones yielding no viable phage decreases with increasing time, a result interpreted from the theory as reflecting the occurrence of G inversions during bacterial growth. Using methods similar to those for calculating mutation rates⁷ it is possible to estimate from the data that the rate of G inversions per cell per generation is close to 0.03, and that the G(+)/G(–) ratio in a culture of 10⁸ bacteria derived from a single cell would be within 5% of unity.

Our data therefore confirm the predictions of the G inversion model. They are also consistent with a less restrictive scheme which allows a small amount of inversion to occur during vegetative phage growth. By themselves, however, the data do not prove that our observations are related to the inversion of G. The correlation comes from experiments of a quite different kind performed by Kamp *et al.*⁸ These authors have isolated two types of Mu mutant which are inversion-defective. One has a deletion covering the right end of the G segment, while the other is presumed to be defective in the production of the inversion enzyme. In these mutants, with G locked in its G(–) orientation, mature phage are produced from induced lysogens, but these phage are non-viable in lytic infection.

Taken together these two sets of results provide strong evidence that in a normal lysogenic culture the cells with the G segment of the prophage in the G(–) orientation produce non-viable phage particles. Presumably the G segment contains, at least in part, some gene whose function is essential in the lytic cycle of Mu; and in one orientation this gene is non-functional. There are two possible roles for this gene. It could be involved in a step which must occur early in the lytic cycle of Mu if phage production is to take place, but is not needed when a prophage is induced, or it could affect the structure of the phage coat so that the Mu DNA is not able successfully to penetrate host cells. In both cases non-viable phage with the G(–) orientation would arise from infection and lysogenisation with a G(+) particle followed by a G(+) to G(–) inversion in the prophage state, and finally by induction. The results of Bukhari and Ambrosio⁹ suggest that the second of these alternatives is correct.

The invertible segment of bacteriophage Mu DNA determines the adsorption properties of Mu particles

INTEREST in bacteriophage Mu stems from the highly promiscuous insertion of its DNA into the genome of its host bacterium *Escherichia coli* (see ref. 1 for review). There are two characteristic features of Mu DNA: first, mature Mu DNA contains heterogeneous host sequences at both ends^{2,3}, and second, near the right end, the S end, of Mu DNA there is a 3,000 base pair sequence that can undergo inversion. The structure of Mu DNA

Fig. 1 Structure of Mu DNA. The different segments of Mu DNA are shown in kilobases. The values for the heterogeneous host sequences at the ends are approximate. When two Mu-DNA molecules carrying G in opposite orientations are denatured and reannealed, the G segment can be seen in the electron microscope as a symmetrical non-renaturable bubble. Less than 1% of the renatured molecules show the bubble if Mu particles are grown by infection of sensitive cells. When Mu is grown by induction of a lysogen approximately 50% of the renatured molecules have the G bubble.

is diagrammed in Fig. 1. The invertible sequence, called the G segment, is remarkable in that it is also found in bacteriophage P1 (ref. 4). The inversion of the G segment in Mu occurs in the prophage state and is independent of the *recA* function of the host⁵. According to Hsu and Davidson⁶, the inversion occurs by recombination between identical but inverted sequences of about 50 base pairs flanking the G segment. Allet and Bukhari⁷ have presented evidence that a Mu function, located within or close to the G segment, is required for the inversion reaction. When Mu particles are grown by induction of a lysogen, about half of the particles contain DNA with one orientation (referred to as the + or *flip* orientation) and the rest of the particles have the G segment in the reverse orientation (the - or *flop* orientation). However, when Mu particles are grown by infection,

Fig. 2 Scheme for identifying the G orientation of Mu DNA. Phage DNA is indicated by solid lines and host DNA by dotted lines. The arrows represent cuts made by restriction endonucleases *PstI* and *KpnI* on Mu DNA in both the *flip* (+) and *flop* (-) orientations. The resulting fragments A, B, C and D give patterns, after electrophoresis in agarose gels, as depicted on the right. Fragments B and D are seen as fuzzy bands because they are linked to host sequences of variable lengths. The size of fragment C, spanning the left region of G and the sequence immediately adjacent to G, depends upon the orientation of G (see the right two columns of Fig. 3).

almost all of the particles contain DNA with the *flip* orientation. The predominance of the *flip* orientation is obtained even if the phage lysate used for infection contained equal numbers of the *flip* and the *flop* orientations. We show here that the predominance of the *flip* orientation after infection results from the inability of the *flop* containing particles to adsorb properly to the bacterial cells.

An important step in explaining the apparent dichotomy of G inversion was made by Chow, Kamp and Kahmann who isolated a mutant of Mu in which the flip-flop reaction of G did not occur⁸. Kamp *et al.* showed that this G inversion (*gin*⁻) mutant produced plaques only when the G segment

Fig. 3 Infection of *E. coli* by ³²P-labelled Mu particles. ³²P-labelled Mu preparation was obtained by induction of strain BUHM8305 (containing the temperature-inducible mutant Mu *cts* 62) and contained both the *flip* and the *flop* particles. *E. coli* K12 strains used for infection were KL16, an Hfr prototrophic strain, and BU1206, a strain carrying the plasmid pRM101. The plasmid pRM101 contains the G segment of phage P1 and apparently has the necessary functions to carry out G inversion. (The plasmid was obtained from D. Vapnek, University of Georgia.) Logarithmically growing cells were centrifuged and resuspended in Mu buffer¹¹. The phage was adsorbed for 15 min at room temperature and the mixture was then diluted 10-fold into prewarmed LB broth at 37 °C containing 2.5 mM Mg²⁺ and 1 mM Ca²⁺ (ref. 11). The mixture was gently shaken at 37 °C. At 10 and 20 min after mixing, the mixture was centrifuged. The cells were washed three times with cold Tris (0.01 M)-EDTA (0.001 M) buffer pH 8.0 and the DNA was phenol extracted. The DNA samples were digested with *KpnI* and *PstI*, the digests were fractionated in 1% agarose gels by electrophoresis and the gels were autoradiographed. The two columns at the right show control Mu DNA preparations (not radioactively labelled), digested with *KpnI* and *PstI*. Mu *cts* represents the standard Mu *cts* 62 lysate made by induction, showing both the *flip* and the *flop* orientation, used for infection experiments. Mu c3, a clear-plaque mutant of Mu, grown by infection shows only the *flip* orientation. After infection of KL16 and BU1206 with Mu *cts* 62 particles, containing both G orientation, only the lower G band representing the *flip* orientation can be seen.

was in the + (*flip*) orientation⁸. To discover in which way the Mu *flop* particles are defective, we have followed the fate of Mu DNA molecules after infection as well as after induction. In these experiments, the orientation of G in the Mu DNA molecules was determined by cleavage with restriction endonucleases. The principle of such analysis has been enunciated by Allet and Bukhari⁷. We used the enzymes *KpnI* (from *Klebsiella pneumoniae*) and *PstI* (from *Providencia stuartii*) Kahmann *et al.*¹⁰ originally determined the cleavage sites for these enzymes in Mu DNA and found that these enzymes, in combination, are very useful in identifying the G orientation. As shown in Fig. 2, the only *KpnI* cleavage site in Mu DNA is located within G, whereas both *PstI* cuts are outside G, one cut being close to the left of G. Depending on the orientation, a different fragment spanning the left part of G is obtained when Mu DNA is cut with a combination of *KpnI* and *PstI*.

We prepared ³²P-labelled Mu particles, as described by Bukhari and Ljungquist¹¹, and infected *E. coli* cells with these particles. At various times after infection, the cells were centrifuged and the DNA was extracted. The orientation of G in the radioactively labelled Mu DNA molecules was examined by autoradiography after cleavage with *KpnI* and *PstI* and electrophoresis in agarose gels. As shown in Fig. 3, only the *flip* orientation could be detected in the cells. Since the starting

Fig. 4 Orientation of G in replicating Mu DNA after infection. Mu *cts* 62 particles grown by induction were used to infect strain BU530, a prototrophic Mu-sensitive strain of *E. coli* K12, and strain BUI253, an *E. coli* strain carrying the plasmid pRM101, which contains the G segment of phage P1 (see Fig. 3). At various times after infection the cells were washed and the DNA was extracted with phenol. The DNA samples were cut with *KpnI* and *PstI* and fractionated in 1% agarose gels by electrophoresis. The fragments were stained with ethidium bromide and photographed under ultraviolet light. The fragments were then denatured in gels, 'blotted' onto nitrocellulose paper and hybridised with ³²P-labelled Mu DNA^{3,13}. *a*, The ethidium bromide stain photograph is on the left and *b*, the autoradiograph after hybridisation. The right-hand column in both (*a*) and (*b*) shows the Mu *cts* DNA extracted from particles used to infect the cells. This DNA shows both G orientations as compared to Mu *c3* DNA grown by infection, which has only the *flip* orientation. It can be seen in the autoradiograph (*b*), that only the *flip* orientation is detected at different times. That the Mu DNA is replicating is shown by the increase in hybridisation of the Mu fragments. The hybridisation background, particularly visible at 40 min after infection, results from random integration of Mu DNA into the host DNA during growth (see ref. 13). Note that in the ethidium bromide stain at the left the G *flip* fragment is visible at 40 min, indicating a large-scale replication of Mu DNA.

Fig. 5 Orientation of G in replicating Mu DNA after induction. Strain BUHM8305, lysogenic for Mu *cts* 62, was heat-induced by shifting the logarithmically growing culture to 44 °C for 20 min and then shifting to 37 °C. Just before induction and at various times thereafter, samples were withdrawn and DNA was extracted with phenol. The DNA was cut with *KpnI* and *PstI*, fractionated by electrophoresis in 1% agarose gels. The fragments were then denatured and transferred to nitrocellulose paper and hybridised to ³²P-labelled Mu DNA^{3,11}. The figure shows the autoradiograph after hybridisation. The two columns at the right are Mu *cts* (showing both G fragments) and Mu *c3* (showing only the *flip* fragment). Both G orientations are detected in the lysogen before induction. After induction both G fragments increase in amount in parallel. The background hybridisation from 20 min onwards reflects integration of Mu at different sites generating random new fragments that hybridise with Mu DNA¹³. By 65 min the culture has undergone substantial lysis, decreasing the yield of cells and thus the intensity of DNA bands is reduced.

lysate contained both the *flip* and *flop* orientations, this shows that the *flop* particles were not able to infect the cells. Similarly, we found that infected cells contained Mu DNA in the *flip* orientation only whereas the supernatant contained a large population of unadsorbed Mu particles with G in the *flop* orientation. Consistent with this result, we have observed that the Mu phage particles purified after induction of Mu-sensitive host contain proportionally more phage with the *flop* orientation than phage prepared from Mu-resistant host. Presumably, this is because of preferential adsorption of *flip* particles to cell debris during purification.

To determine the orientation of G in the replicating Mu DNA molecules, we either infected *E. coli* cells with unlabelled Mu particles or induced Mu lysogens. The DNA was extracted at various times after infection or induction and cleaved with *KpnI* and *PstI*. The fragments were separated in agarose gels by electrophoresis, denatured and transferred to nitrocellulose paper by the procedure of Southern¹². After hybridisation with ³²P-labelled Mu DNA, the DNA fragments hybridising to Mu DNA (that is, Mu fragments) were visualised by autoradiography, as described previously^{3,13}. Only one orientation of G was detected in replicating Mu DNA, as late as 40 min after

infection (Fig. 4). Even in a strain that contained the G segment of phage μ cloned in a plasmid, and thus had the G inversion system of μ only the *flip* orientation of G could be observed. This shows that the rate of G inversion is slow and that most of the infecting molecules remain in the *flip* configuration throughout the lytic cycle. As shown in Fig. 5, both G orientations were detected in a *Mu cts* lysogen, before or at various times after induction. This result thus provides direct proof that G inversion occurs in lysogenic cells before induction and that, after induction, both orientations replicate equally well. Interestingly, the G orientation of replicating *Mu* DNA can be determined after infection or after induction, even without DNA-DNA hybridisation and autoradiography. This is because as *Mu* replicates and *Mu* DNA copies accumulate, the *Mu* G fragments stand out above the background. (See Fig. 4.) We have used this method to screen for *Mu* mutants defective in G inversion (unpublished).

We conclude from these experiments that the reason why *Mu* particles with only the *flip* (or +) orientation of G are obtained after infection is that the particles with G in the opposite orientation (*flop* or - orientation) fail to infect the host cells. This block in infection seems to result from an inability of *Mu flop* particles to adsorb to the cells. It is not clear whether the *flop* particles do not adsorb at all or whether the adsorption is reversible such that the *flop* particles are easily detached from the cell surface. Apparently, when lysates are prepared by infection there is a selection for the *flip* particles at each infectious cycle. Since the rate of G inversion is slow, only *Mu* particles with the *flip* orientation accumulate in the lysates prepared by infection. These results extend the observation of Kamp *et al.*⁹, on the non-viability of the *flop* particles and complement the results of Symonds and Coelho¹⁴ who have shown that only some of the cells in a culture of a *Mu* lysogen give rise to infectious centres and that the rate of G inversion is slow that is 0.03 per cell per generation.

The inability of the *Mu flop* particles to adsorb properly indicates that these particles lack a phage component needed for adsorption. Evidently, this component is made only when G is in the *flip* orientation. This case provides an interesting example of the *flip-flop* control of gene expression. A similar mechanism has been postulated for phase variation in *Salmonella*¹⁵.

We thank Phyllis Meyers and R. J. Roberts for providing some enzyme preparations and M. S. DuBow and R. Gudor for useful discussions. This work was supported by a grant from the US NSF (PCM 76-13460). A. I. Bukhari holds a Career Development Award from the NIH.

Inversion of the G DNA segment of phage *Mu* controls phage infectivity

THE 3,000 base pair-long G segment of temperate coliphage *Mu* DNA has been shown to invert spontaneously with high frequency^{1,2}. Inversion, which is independent of the *rec* system of the host³, results in *Mu* phage with the G segment in either orientation. Nearly equal numbers of both G orientations are observed in a lysogen or when a lysate is obtained by induction of a lysogen. When phage is grown by a series of infections one and the same G orientation prevails⁴. One attractive explanation for these observations implicates inversion of the G segment in the control of phage or host functions. We report here experiments which show that the orientation of the G segment determines infectivity of *Mu* phage particles and that G inversion is mediated by a phage-specific enzyme system.

In our studies we used a recently isolated plaque-forming substitution mutant, *Mu* 445-5, which no longer inverts its G segment but apparently has an intact G region⁵. We refer to this phenotype as *gin*⁻ for G inversion. The orientation of the G segment in *Mu* 445-5 is the same as that found to predominate after lytic infection. We shall call this orientation G(+) and the opposite orientation G(-). To test possible effects of G orientation on *Mu*, we attempted to invert the G segment of *Mu* 445-5 *in trans* by using a helper phage. We constructed a double lysogen with *Mu* 445-5 on the host chromosome and a *Mu gin*⁺ helper inserted in an episome. This double lysogen was induced and the DNA of the phage progeny was analysed by heteroduplex formation with appropriate reference *Mu* DNA (Fig. 1). The G segment of *Mu* 445-5 phage DNA produced from the double lysogen was found in either orientation, indicating that the *gin*⁻ phenotype of *Mu* 445-5 is recessive and can be complemented by a *gin*⁺ phage. This result shows that at least part of the enzyme system responsible for G inversion is specified by *Mu* itself. Removal of the helper prophage from the double lysogen should result in subsequent dilution of the *gin* enzyme from the cell and thus freeze the G segment of the *Mu* 445-5 prophage in either the G(+) or the G(-) configuration. Strains that had spontaneously lost the episome carrying the *gin*⁺ helper prophage fell into two classes with approximately equal frequency. The first class released normal plaque forming *Mu* 445-5 phage, while the second class lysed after heat induction but produced no plaque forming phage. Nevertheless these lysates contained phage particles which could be banded in caesium chloride density gradients and from which normal size DNA could be isolated. The yield and density of these phage particles were virtually the same as for the plaque forming *Mu* 445-5 phage. Even concentrated lysates did not result in killing or lysogenisation when spotted on a lawn of *Mu*-sensitive bacteria. As determined by restriction enzyme analysis (Fig. 2), the defective particles obtained from several independently isolated lysogens always contained *Mu* 445-5 DNA with the G segment in the G(-) configuration, whereas all plaque producing lysogens yielded *Mu* 445-5 phage with the G segment in the G(+) orientation. The *Mu* 445-5 *gin*⁻ G(-) lysogens were then re-exposed to the *gin* system provided by the episome with the *Mu gin*⁺ helper prophage. As before, removal of the episome resulted in two classes of lysogens—those producing non-infectious *Mu* 445-5 G(-) phage and those yielding infectious *Mu* 445-5 G(+) phage. These results show that the only difference between the defective and non-defective *Mu* 445-5 phage particles is the orientation of their G segments, and that the inability of the *Mu* 445-5 *gin*⁻ G(-)

prophage to produce infectious phage can be reversed by inverting its G segment from the (−) to the (+) orientation. Figure 3 illustrates and summarises these experiments.

Because Mu 445-5 has an insertion (which we have shown to be part of insertion sequence IS2) we could not generalise

this conclusion with absolute certainty. However, indirect evidence suggests that Mu wild-type phage with a G(−) configuration is also defective. It was found that not all cells lysogenic for a temperature-inducible Mu produce phage after heat induction (D. K., unpublished). In view of the

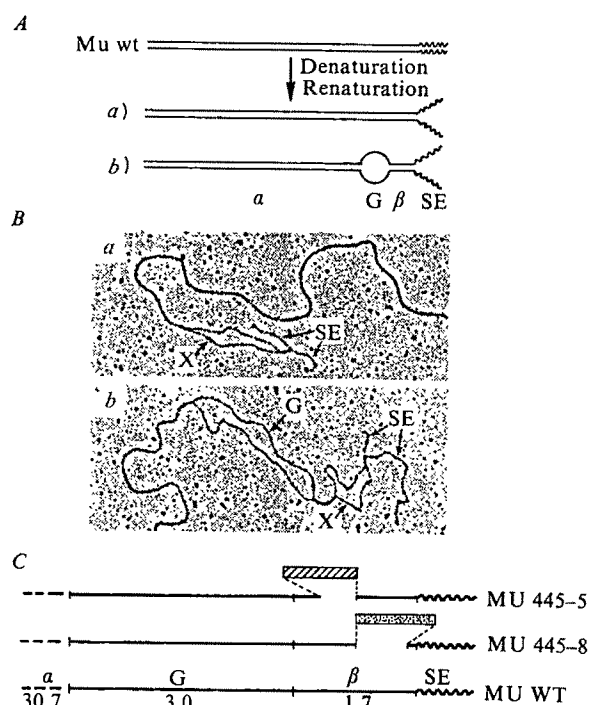

Fig. 1 Determination of the G segment orientation by heteroduplex analysis. *A*, Schematic presentation of DNA structures observed after denaturation and self-annealing of wild type Mu DNA extracted from phage grown by induction⁴. The various segments are designated as alpha, G, beta, and split ends (SE). The lengths of the heterogeneous bacterial DNA comprising the split ends (—) are variable and range from a few hundred to about 3,000 nucleotides. In about half the heteroduplexes (*a*), the G segment is duplex. The single-stranded G loop in the other half (*b*), is due to annealing of Mu strands with G segments in opposite orientations, a result of inversion. *B*, EM heteroduplex determination of the orientations of the G segment in Mu 445-5 grown in the presence of a helper phage. DNA species were denatured with 0.2 M NaOH, neutralised with 2 M Tris-HCl, pH 7.2, and then reannealed at room temperature for 50 min in 50% formamide at a total DNA concentration of 4 μ g ml⁻¹. Renaturation was stopped by dialysis against 0.01 M Tris, 0.001 M EDTA, pH 8.5 at 4°C. Sample grids for electron microscopy were prepared by the formamide variation of the Kleinschmidt technique¹¹⁻¹³. Micrographs were taken with a Philips 201C electron microscope and printed at about the same magnification. Only the right ends of the heteroduplexes are shown. DNA was isolated from phage produced after heat induction of the double lysogen DK850 which is $\Delta pro lac Sm^R$ (Mu cIts62 445-5)/F' *pro lacI::Mu cIts62* Lts (the Mu Lts phage was obtained from A. I. Bukhari¹⁴). The orientation of the G segment of the Mu 445-5 phage was determined from heteroduplexes formed with Mu 445-8. Mu 445-8 is a deletion-substitution mutant in the right half of beta⁵ and was propagated by infection so that its G segment was in the (+) orientation. Mu 445-5 is a deletion substitution mutant in the left half of beta⁵. Heteroduplexes between Mu 445-5 and Mu 445-8 can be distinguished from those of Mu 445-5/Mu or Mu/Mu 445-8 because of their non-overlapping substitution-deletions (see *C*). *B-a*, A heteroduplex of Mu cIts62 445-5/Mu 445-8, showing a duplex G region, a split end and the noncomplementary substitution loop (X) in beta. The G segment of Mu cIts62 445-5 is in the G(+) orientation. *B-b*, A heteroduplex of Mu cIts62 445-5/Mu 445-8 showing the noncomplementary loop in the beta region identical to (*a*), a split end and a G loop, indicating that the G segment of the Mu cIts62 445-5 phage is present in the G(−) configuration. *C*, Diagrammatic map of the G beta region of phages Mu 445-5 and Mu 445-8. Solid lines represent Mu DNA. Deletions are indicated by gaps and substitutions by shaded bars. Sizes of the individual segments are given in kilobase pairs.

Fig. 2 Determination of the G segment orientation by agarose gel electrophoresis of Mu DNA cleaved with restriction enzymes. The principle of analysing the G segment orientation with restriction enzymes, first described by Allet and Bukhari who used the enzyme *HindIII*⁷, is based on the cleavage of Mu DNA with an enzyme that cleaves the G segment at least at one asymmetrically located site, such that DNA containing G in the (+) orientation produces a restriction fragment of one size while DNA with G in the (−) orientation yields a fragment of different size. Except for Mu *vir*, which was grown by infection, all other phages were propagated by induction. Phage and DNA preparation have been described previously¹⁵. Samples of 2 μ g DNA were digested at 37°C with an appropriate amount of *PstI* and *KpnI* restriction endonucleases in a buffer containing 0.06 M Tris-HCl (pH 7.9), 0.06 M MgCl₂, 0.06 M 2-mercaptoethanol. After digestion, sucrose and bromophenol blue were added to final concentrations of 5% and 0.02% respectively. Slab gel electrophoresis was through 1.2% agarose for 4 h under a constant voltage of 120 V, essentially as described by Sugden *et al.*¹⁶. After staining with ethidium bromide, bands were visualised by excitation with short wave ultraviolet light and photographed through a Kodak no. 23 red filter with Polaroid film P/N55. The *PstI*-*KpnI* fragments of different size are obtained in digests of Mu cIts62 DNA (*a*), because of the presence of both G segment orientations. The smaller of these fragments is characteristic of the orientation found in Mu *vir* (*b*) and in Mu cIts62 445-5 G(+) DNA and is indicated by G(+). The larger fragment is produced when the G segment is in the G(−) configuration, as in Mu cIts62 445-5 G(−) DNA (*d*). It co-migrates with the diffuse right end fragment. The largest band represents the *PstI* fragment generated from the alpha region of the Mu genome. The second largest band represents the *PstI* fragment from the right end, which remained uncleaved by *KpnI* due to low enzyme activity. The smallest fragment originates from the left end of the molecule.

results with Mu 445-, it was tempting to speculate that this phenomenon, found independently by Symonds and Coelho (personal communication), reflects the existence of a sub-population of Mu wild-type lysogens that produces only defective G(-) phage particles on induction. The Mu 445-5 *gin*⁻ lysogens provided the necessary control to test this assertion, because a population of these lysogens is homogeneous with respect to the orientation of the G segment. In fact, every Mu 445-5 G(+) lysogen gives rise to an infectious centre after heat induction. In contrast, for every *gin*⁺ strain tested thus far the frequency of infectious centres may vary from experiment to experiment but never reaches 100% (Fig. 4). Furthermore, this variation seems to reflect the proportion of the prophages which are in the G(+) orientation, because analysis of Mu *gin*⁺ DNAs shows that the ratio of G(+) to G(-) phage also varies. When phage lysates were prepared from the same cultures that had been tested for infectious centres, and DNA from these phages was analysed for the orientation of G segments, we found that the percentage of phage chromosomes with a G(+) orientation was directly proportional to the yield of infectious centres of each culture (Fig. 4). If one assumes that the G segment hardly ever rotates in an induced lysogen, most lysogens would produce either G(+) or G(-) phage. Because there is no significant difference in the yield of G(+) and G(-) phage particles, the ratio of G(+) to G(-) phage in the lysate would then equal the ratio of G(+) to G(-) prophages at the time of heat induction. Thus the yield of infectious centres can be correlated with the ratio of G(+) to G(-) prophages. This implies that Mu *gin*⁺ prophages, which are temporarily in a G(-) configuration when heat induced, produce defective phage particles.

Fig. 3 Inversion of the G segment of Mu 445-5 promoted by a Mu helper prophage. DK984: Δlac pro Sm^R (Mu cIts62 445-5 G(+)) *gin*⁻ was used as a recipient for mating with DK654: Δlac pro Sm^R/F' pro *lacI*:: Mu cIts62 Lts G(+) *gin*⁺. Growth and mating conditions were described by Miller¹⁸. Transconjugants were selected as red colonies (*lac*⁺) on MacConkey lactose streptomycin plates. The double lysogens were grown overnight before they were streaked out on MacConkey lactose plates. Colonies that had been cured of the episome spontaneously occurred with a frequency of about 0.1-1% and were identified as white colonies (*lac*⁻). After restreaking, these colonies were tested for Mu phage production by stabbing them into a lawn of Mu-sensitive indicator bacteria. Thirty to fifty colonies were tested in each step. Three cycles of conversion of G(+) to G(-) and back to G(+) were conducted without any apparent change in the outcome of the experiment. To exclude the possibility that G segments are exchanged by recombination between the episome and chromosome rather than that they are inverted intramolecularly, two control experiments were performed. Rotation of the G segment, G(+)→G(-)→G(+), was not affected by a *recA* mutation of the host. Second, an episome carrying a Mu 445-5 *gin*⁻ G(+) prophage instead of a Mu *gin*⁺ helper was introduced into a strain lysogenic for Mu 445-5 *gin*⁻ G(-) and this double lysogen was subjected to the procedure as described above. Out of 36 colonies that had been cured of the episome, none had acquired a Mu 445-5 *gin*⁻ G(+) prophage.

Fig. 4 Infectious centre production of various strains lysogenic for Mu and its correlation to the orientation of the G segment. Analysis of phage DNAs with restriction enzymes *Pst*I and *Kpn*I was as described in Fig. 2. Samples of the lysogenic cultures were taken immediately before heat induction and were diluted in broth to about 1×10^8 colony forming units ml⁻¹. One aliquot was plated at 34 °C to measure the number of cells. In order to determine the number of infectious centres, another aliquot was heat induced at 42 °C for 10 min, mixed with Mu-sensitive indicator bacteria and plated with soft agar at 40 °C. The ratio of infectious centres to colony forming units is given in % of average numbers derived from 7-10 parallel platings. In every experiment, 50-100 colonies from plates used to determine the number of colony forming units were routinely tested for lysogeny and all were found to produce plaque forming phage. This excludes trivial explanations for the lower yield of infectious centres such as frequent spontaneous loss of the prophage or frequent mutation resulting in a defective phage. The results for the following Mu lysogens are shown: a, DK948: (Mu cIts62 445-5 G(+)); b, DK588: (Mu cIts62 *mom*⁻); c, DK392: (Mu cIts62 *cII*31); d, DK1018: (Mu cIts62 445-5 G(-))/F' pro *lacI*:: Mu cIts62 445-5 G(+); e, DK394: (Mu cIts62); f, DK722: (Mu cIts62 *mom*⁻) Mu⁺; g, DK947: (Mu cIts62 445-5 G(-)). The double lysogen in (d) is included as a standard for a 50:50 ratio of G(+) and G(-) molecules. The bacterial hosts are CSH50: Δlac pro Sm^R in (a), (d), (g) and the prototrophic K12 strain W8 in (b), (c), (e) and (f). DK722 was derived from DK588 by selecting for resistance against Mu *vir*. The *mom*⁺ and the *cII*¹⁸ mutations have been described elsewhere. The absolute numbers for infectious centres and the G(+)/G(-) ratios are not reproducible for a given Mu lysogen unless it is *gin*⁻, and the numbers differ from culture to culture within the range that is shown here. Only the correlation between % infectious centres and G(+)/G(-) is consistently found to be the same. The different genetic make-up of the lysogens therefore does not account for the difference in absolute values.

This finding is consistent with our results obtained in *gin*⁻ conditions.

These results have to be reconciled with the current view that all essential functions of phage Mu are located in the alpha region to the left of the G segment⁸. The *mom* function, which is possibly controlled by G inversion, is not essential for Mu growth⁸. Our preliminary findings that Mu 445-5 G(-) phage is deficient for the S gene product raise the possibility that expression of the S function depends on the orientation of the G segment. The S gene, which has been mapped to the immediate left of the G segment³, could in fact be located partially in the G segment and then be split by G inversion. A recent refinement of the correlation between the physical and genetic map at this particular location (M. Howe, personal communication) seems to support this view. An alternative explanation

would be that a promoter is coupled to the S gene only when the G segment is in the (+) orientation. This kind of mechanism has been proposed in the case of *Salmonella* phase variation⁹. Genome rearrangement has also been envisaged as a means of controlling gene expression in eukaryotic cells¹⁰. Therefore the *gin* mediated inversion of the G segment in phage Mu is a useful paradigm for hypothetical control mechanisms that might play a part in the expression of genes in other prokaryotic as well as eukaryotic organisms.

Involvement of phage Mu-1 early functions in Mu-mediated chromosomal rearrangements

THE temperate phage Mu-1 not only integrates at any location in the chromosome of its host *Escherichia coli*¹ but also provokes different types of chromosomal aberrations: insertions of extrachromosomal circular DNA^{2–4}, translocations, deletions and inversions of chromosomal segments (refs 5, 6, Howe and Bukhari, unpublished results and M.F., in preparation). Immunity to phage Mu prevents the induction of such events, indicating that Mu gene expression is required for these rearrangements. Furthermore, the direct participation of Mu DNA in the generation of chromosomal aberrations is demonstrated by the observations that one entire Mu genome is always adjacent to the site of the deletions, two entire Mu genomes in the same orientation flank the inserted and translocated DNA fragments, and inverted chromosomal segments are surrounded by two entire Mu genomes in opposite orientations (ref. 22 and M.F., in preparation). Dependence of such Mu-induced alteration on the A and B early phage functions was investigated. *A*[–]

mutants of Mu are unable to mediate all the events tested, while *B*[–] mutants still promote deletion. Based on the results presented here, and on other data, we propose that the A function directly concerns the insertion of the phage and that the B gene codes for a replication function.

The molecular mechanism by which Mu causes chromosomal rearrangements is not known, although all observations made so far are consistent with the idea that the Mu enzymes and the sites on Mu DNA used for normal Mu integration are necessary and sufficient for Mu to mediate these events⁸. All mutants of Mu which result in altered capacity to integrate have been found to affect two of the early functions, either A or B. Such mutants neither replicate nor synthesise late Mu-specific mRNA^{9,10} and on infection of a sensitive host they are unable to mediate integration of extrachromosomal DNA^{2,3}. When present as an induced prophage, *A*[–] mutants still show that defect, but *B*[–] mutants do efficiently mediate integration events⁴. We have studied the capacity of *A*[–] and *B*[–] prophages to mediate deletions and translocation events.

Mu-mediated deletion formation can be readily detected in strains which carry a *Mu*c62 prophage in the *trp* operon (*trp* : : *Mu*c62). After growth at 37 °C, leading to partial induction of the thermoinducible prophage, clones with a deletion in the *tonB*–*trp* region (for revised map of *E. coli*, see ref. 11) may be selected (at 30 °C) for their resistance to phage Φ 80 and the col VB colicins. The frequency at which *tonB* deletions appear in partially induced Mu lysogens is $\sim 10^{-4}$, that is ~ 500 times higher than the spontaneous frequency of 10^{-8} – 10^{-7} at which deletions are formed in that particular region (see Table 1). *sup*⁺ and *sup*[–] strains were isolated which carry either a *Mu*c62 *Aam* or a *Mu*c62 *Bam* or a *Mu*c62 X (*Mu*c62B : : *IS*1 (ref. 12)) prophage in the *trp* operon. These were induced at 37 °C (42 °C in the case of Mu X lysogen) and the frequencies at which *tonB*–*trp* deletions were generated were measured. The frequency of appearance of *tonB* clones

Table 1. Induction of *tonB* deletions by induced *Mu*c62 *A*[–] and *Mu*c62 *B*[–] prophages inserted in the *trp* operon

Induced strain		Frequency of appearance of <i>tonB</i> clones
<i>supF</i> [–] <i>trp</i> : : (<i>Mu</i> c62 <i>Aam</i> 1093)	Positive control	2.6×10^{-5}
<i>supF</i> [–] <i>trp</i> : : (<i>Mu</i> c62 <i>Bam</i> 1066)		4×10^{-5}
<i>sup</i> ⁺ <i>trp</i> : : (<i>Mu</i> c62)		10^{-4}
<i>sup</i> ⁺ <i>trp</i> : : (<i>Mu</i> c62 <i>Bam</i> 1066)		1.1×10^{-4}
<i>trp</i> : : (<i>Mu</i> c62 X3600)		2×10^{-4}
<i>sup</i> ⁺ <i>trp</i> : : (<i>Mu</i> c62 <i>Aam</i> 1093)		1.8×10^{-6}
<i>sup</i> ⁺ (<i>Muc</i> ⁺) <i>trp</i> : : (<i>Mu</i> c62)	Negative control	1.2×10^{-6}
<i>supF</i> [–] <i>trp</i> ⁺		2×10^{-7}

sup⁺ strains are derived from CSH54 (ref. 17) and are Δ *pro-lac*, *his*[–], *thi*[–] str^R. *supF*[–] strains are derived from QD5003 (ref. 18) HfrH *supF*[–]. The *trp* : : (*Mu*c62 X 3600) is derived from HC-B-7-18 Hfr P4X *metB*, *argEC-1*. *Muam* mutations were described by Howe¹⁸. Cultures were grown overnight at 37 °C (42 °C) in L broth, starting from a single colony, without aeration. One loopfull of each culture was resuspended in 5 ml L broth and incubated up to stationary phase without aeration at 37 °C (42 °C). Cultures were titrated on LB plates at 30 °C. 0.1 ml of the 10^{-1} dilutions was mixed with 0.2 ml of Φ 80vir (10^{11} phage ml^{–1}) and 0.2 ml of a col VB lysate, incubated for 20 min at 30 °C and titered on LB plates, seeded with 0.1 ml of the col VB lysate. The frequency of appearance of *tonB* clones was calculated from the ratio no. of clones on LB + col VB / no. clones on LB.

* Experiment performed at 42 °C: 10 *tonB* clones derived from the *Mu*c62 X lysogen were analysed. They all retained the immunity and S genes of the Mu prophage, showing that none of the deletions extended into the Mu prophage. This was done to check that none of the deletions was mediated by the *IS*1 present in the B gene of the *Mu*c62 X rather than by Mu itself.

Table 2 Translocation of the *asd* gene on to an *Flacpro* episome by *Mucts62 Aam1093* and *Mucts62 Bam1066* prophages inserted in *malA*

Donor	Frequency of <i>asd</i> ⁺ translocation
(<i>Mucts62 Aam1093</i>) <i>sup</i> ⁺ / <i>Flacpro</i>	4×10^{-8}
(<i>Mucts62 Aam1093</i>) <i>supF</i> ⁻ / <i>Flacpro</i>	3×10^{-8}
(<i>Mucts62 Bam1066</i>) <i>sup</i> ⁺ / <i>Flacpro</i>	2×10^{-8}
(<i>Mucts62 Bam1066</i>) <i>supF</i> ⁻ / <i>Flacpro</i>	5×10^{-8}

The strains were grown in LB broth at 30 °C to $\sim 2 \times 10^8$ ml⁻¹; 0.5 ml of both the donor *Flacpro/malA* :: (*Mucts62am*) *recA* *sup*⁺ or *supF*⁻ and the recipient *argG*, *metA*, *asd*, *thi*, *lac*, *recA*, *Rif*^R (*Muc*⁺), were mated for 2 h at 42 °C. *Asd*⁺ sexductants were selected by plating dilutions of the mating mixture on minimal medium supplemented with glucose, arginine, methionine and rifampicin. The frequency of *asd* transfer which is taken as the measure of Mu-mediated translocation, is given by the ratio no. of *asd* sexductants/input of *F'* cells.

in strains used as positive control, that is, the *supF*⁻ *trp* : : (*Mucts62 Aam*) and *supF*⁻ *trp* : : (*Mucts62 Bam*) in which the A and B mutations were suppressed, was $\sim 10^{-4}$. The same frequency was found with *sup*⁺ strains lysogenic for either *MuBam* or *MuX* mutants where the B gene was not expressed. However, in the *sup*⁺ strain lysogenic for *MuAam*, *tonB* clones appeared at a frequency of 10^{-8} , this being the same frequency as that found in the strain used as negative control (*trp* : : (*Mucts62*) (*Muc*⁺)) in which no thermal induction of Mu occurred.

This clearly shows that the A gene product is required for Mu-mediated deletion formation, while the B gene product is dispensable. Mu-mediated translocation occurs both after infection with Mu of a sensitive bacterium and in induced Mu lysogens. This can be readily detected in an *F'* strain, by transferring the episome to a recipient in which it is possible to select for plasmids which have acquired a given translocated marker. When the prophage is fully induced proximal and distal host markers are translocated at the same frequency⁷. We tested the ability of *A*⁻ and *B*⁻ induced Mu prophages to mediate translocation of proximal markers. We isolated *sup*⁺/*F'* *pro lac* strains, carrying either a *Mucts62 Aam* or a *Mucts62 Bam* prophage in the *malA* gene, and their *sup*⁻ derivative which were used as positive controls. These strains were mated at 42 °C with a recipient suitable for selection of transferred *F'* having eventually acquired and *asd* gene (which is located near *malA* (ref. 11)). The results in Table 2 show that translocation of the *asd*⁺ allele occurs at a frequency of 3.5×10^{-8} in the *sup*⁻ lysogens, while in the *sup*⁺ lysogens this frequency is $\sim 4 \times 10^{-8}$, thus ~ 100 times lower. Translocation by an induced *Mucts62 X* prophage was also tested (data not

shown) and was found to be negative. From these results we conclude that both the A and B gene products are required for Mu-mediated translocation.

As an alternative approach, prophages affected in their ability to mediate translocation, were isolated after treatment of a *Mucts62* lysogen with nitrosoguanidine. The strain used contains an *F' lac* episome, and a *Mucts62* prophage in the *trp* operon. After mutagenesis we screened for clones which after induction neither produced viable phage nor transferred episomes with translocated markers. We shall ignore mutants which were found to directly affect the transfer of the *F'* episome (4% of the total number of clones screened). Ten mutants (1.3% of the clones tested) in which the deficiency was found to be in the Mu prophage were analysed for their ability to mediate deletion of the *tonB* chromosomal marker and to translocate markers proximal to the prophage, on to the *F lac* episome. They were also tested for their capacity to complement *A*⁻, *B*⁻ and *L*⁻ mutants of Mu. All mutants fall into two classes (see Table 3): some (2/10) complement *A*⁻ and *L*⁻, but not *B*⁻ mutants of Mu, could mediate formation of *tonB* deletions and could not mediate translocation; the others (8/10) complemented the *L*⁻ mutant; some complemented *B*⁻ mutants but none complemented *A*⁻ mutants, nor could any mediate either deletion formation or translocation of chromosomal markers. This confirmed the findings that the B gene product is not required for deletion formation while the A gene product is necessary, and that both A and B products are essential for Mu to mediate translocation. Mu-mediated deletions and insertions are events which can occur in an induced Mu lysogen at the site where the prophage is originally located and therefore do not necessarily involve transposition of Mu DNA. On the other hand, Mu-mediated translocation always involves transposition of the Mu genome. On the basis of our previous work⁸, we conclude that two Mu copies are always involved in Mu-mediated illegitimate recombination. As long as the Mu prophage is integrated into the host chromosome which is the case in the induced lysogen since no extensive excision of the Mu genome occurs after induction¹³, the two copies of Mu can be generated through the replication of the host genome. However, as soon as Mu leaves the host chromosome, most probably as a heterogeneous circle containing host DNA covalently linked to one Mu copy¹⁴⁻¹⁶ it must be able to replicate by itself to generate two copies. One would thus expect Mu replication function(s) to be dispensable for those chromosomal rearrangements which can occur at the site of the prophage, that is, deletions and insertions, but these

Table 3 Properties of the prophage mutants selected for their inability to transpose host markers

Mutant isolated	Frequency of translocation on <i>Flac</i> of		Frequency of <i>tonB</i> deletion	Complementation of mu mutants in gene		
	<i>pyrF</i> ⁺	<i>thyA</i> ⁺		<i>A</i>	<i>B</i>	<i>L</i>
1	2×10^{-7}	3.4×10^{-8}	5.3×10^{-6}	—	+	+
2	1.6×10^{-6}	9×10^{-8}	5×10^{-6}	+	—	+
3	1.5×10^{-7}	6×10^{-7}	23×10^{-6}	—	+	+
4	1.6×10^{-7}	10^{-6}	1.1×10^{-4}	+	—	+
5	8×10^{-8}	1.6×10^{-7}	1.7×10^{-6}	—	+	+
6	2.4×10^{-7}	1.6×10^{-8}	4.7×10^{-6}	—	—	+
7	4.7×10^{-7}	2.9×10^{-6}	2.2×10^{-6}	—	—	+
8	8×10^{-8}	2.5×10^{-6}	6.5×10^{-6}	—	—	+
9	2.4×10^{-7}	4×10^{-6}	5.2×10^{-6}	—	—	+
10	1.2×10^{-7}	2×10^{-8}	4.5×10^{-6}	—	+	+
<i>Mucts62</i>	2.3×10^{-8}	8×10^{-8}	1.5×10^{-4}	+	+	+

MuA⁻ is *Mucts62 Aam1093* (ref. 19). *MuB*⁻ is *mucts62 Bam1066* (ref. 19), *MuL*⁻ is *Mucts62 Lts5017* (ref. 20). The strain from which the mutants were derived contained a *Mucts62* prophage in the *trp* operon and an *Flac* episome. The method for measuring the *tonB* deletion frequency is described in Table 1. The frequency of translocation of the *pyrF*⁺ or *thyA*⁺ alleles on to the *Flac* were determined as described in Table 2 using a *pyrF*⁻, *thyA*⁻, (*Muc*⁺), *Spc*^R *recA*⁻ recipient. Complementation tests were performed by introducing *F' lac Mucts62am* episome in *F*⁻ *recA*⁻ derivative of the mutated lysogens and measuring phage production on *sup*⁺ and *sup*⁻ indicator bacteria, after induction of the dilysogens.

functions should be essential for translocations which always involve transposition of Mu DNA and duplication of the phage genome outside of the host chromosome. This is the case for the B gene product, and therefore we propose that the B gene product is involved in Mu replication. Mu integration function(s) are, on the contrary, expected to be required for all Mu-mediated chromosomal rearrangements. Thus, as only A^- mutants of Mu are unable to mediate deletion formation, integration of extrachromosomal DNA and translocation, we propose that the A gene product is an integration function. The same conclusion has been reached independently by O'Day *et al.*²¹: they found that only MuA^- mutants are completely defective for integration.

Part of this work was completed while M.F. was a post doctoral fellow at the Departamento de Investigaciones Biomédicas, UNAM, Mexico; O.H. was a EURATOM fellow; A.T. is Chargé de Recherches from the Belgian FNRS.

Immunoglobulin light-chain structural gene sequences cloned in a bacterial plasmid

IMMUNOGLOBULIN light-chain mRNA molecules and their cDNA transcripts have served as molecular probes in hybridisation experiments designed to quantify the number of immunoglobulin genes¹⁻¹³ and to characterise the arrangement of these genes in the mammalian genome^{14,15}. In other studies these mRNAs and cDNAs have been used as substrates for nucleotide sequence analyses to define the structural gene encoding

immunoglobulin light chains^{16,17}. Unfortunately, two central technical problems have developed during these studies. First, the immunoglobulin mRNA cannot be obtained in amounts sufficient for many experiments. For example, determination of the complete nucleotide sequence of this RNA remains difficult without more material. Second, immunoglobulin mRNA cannot be obtained as a homogeneous RNA completely free of other RNA species. These impurities have probably interfered with several hybridisation studies. In order to obtain a substrate for nucleotide sequence analysis as well as to provide a pure hybridisation probe we have cloned the DNA (cDNA) complementary to the immunoglobulin light-chain (kappa) mRNA from the mouse myeloma MOPC-149. The

Fig. 1 DNAs from plasmids (1) pCRI, (2) pBG2 (ref. 20), and (3) pCRI- κ 40 were digested with S1 nuclease in 40% formamide and fractionated on a 2% agarose gel run from top to bottom. The exact conditions for digestion of the DNA are as described by Hofstetter *et al.*²⁵. *a*, Bands identified by ethidium bromide staining. *b*, An autoradiogram obtained after the DNA from the lanes shown in (*a*) was denatured and transferred to a nitrocellulose filter, and hybridised to ³²P-MOPC-149 cDNA as described by Southern²⁷. The size of the pCRI- κ 40 insert fragment was determined to be 700 base pairs by calibration with *Hae*III fragments of ColEI DNA (marker fragments not shown). The pBG2 insert fragment (*a*, lane 2) is 576±50 base pairs (ref. 15).

Fig. 2 Radioautograph for determination of the nucleotide sequence starting from the *Hae*III site in *pCRI-κ40* reaching towards the *Pst*I site. The 850-base pairs *Hae*III fragment found in digests of *pCRI-κ40* was isolated from an acrylamide gel, kinased, and cleaved with *Pst*I (see Fig. 3 for location of restriction sites). The 325-base pair fragment generated in this way was then subjected to the reactions described by Maxam and Gilbert³⁰. G, A, T, C across the top of the radioautograph indicate the specificity of the reaction. Two sets of reactions were electrophoresed for 19 h (a) and 8 h (b). The letters on the right side of the figure indicate the nucleotide sequence suggested by the band pattern. A few of the deduced residues are indicated as examples. These nucleotides correspond to residues 3–17 from the *Hae*III cleavage site. The complete sequence deduced from these autoradiograms is shown in Fig. 3.

plasmid *pCRI-κ40* is shown here to contain sequences corresponding to 700 bases of the immunoglobulin mRNA.

The cDNAs derived from several polyadenylated mRNAs have been converted into double-stranded DNA and joined to plasmid vectors using the poly dA-T tailing procedure¹⁸ or the synthetic oligonucleotide linker method¹⁹. The insertion of rabbit β-haemoglobin²⁰ and rat insulin¹⁹ mRNA sequences into plasmids has been confirmed by nucleotide sequence

analysis of the cloned DNA segment. Other insert carrying plasmids have been shown to hybridise to MOPC-173 immunoglobulin light-chain cDNA²¹, mouse α and β haemoglobin cDNA²², and ovalbumin cDNA²³, suggesting that the sequences of these mRNAs have also been cloned in plasmids. We used a slight modification of the poly dA-T tailing procedure, first used for cloning the rabbit β haemoglobin cDNA^{18,20} sequences, to clone immunoglobulin cDNA and have unambiguously confirmed its presence in the clone by determining a portion of its nucleotide sequence.

We began with the total poly A-containing mRNA found on the polysomes of the mouse myeloma tumour MOPC-149 rather than pure immunoglobulin mRNA. (The purest fractions of 14S mRNA were reserved for the screening procedures used to identify clones containing immunoglobulin sequences.) Immunoglobulin light-chain mRNA is only 10–30% of this RNA population. The cDNA obtained by reverse transcription of this population of mRNAs was found to be very heterogeneous in size, 50–2,000 bases in length (J.G.S., unpublished). Nevertheless, we used this heterogeneous cDNA as a substrate for *Escherichia coli* DNA polymerase I to generate double-stranded DNA hairpin structures. These hairpin structures were converted into double-stranded DNA by digestion with S1 nuclease. Then, poly dA stretches were attached to the double-stranded DNA, and poly dT stretches were added to linear plasmid *pCRI* DNA (which had been cleaved with *Eco*RI) by the action of terminal nucleotidyl transferase (kindly provided by R. L. Ratliff) using the procedure described by Wu *et al.*²⁴. Finally, the poly dA 'tails' on the double-stranded DNA were annealed to the poly dT 'tails' of the plasmid DNA to form circular hybrid molecules.

In this way a large number of hybrid molecules were formed. To amplify and purify a hybrid molecule containing immunoglobulin gene sequences we used these hybrids to transform *E. coli*. The NIH Advisory Committee on Recombinant DNA has decided that this type of experiment requires an EK2 host-vector system and a P3 level of physical containment. We complied with these requirements. We therefore used the crippled EK2 host, *E. coli* strain κ1776, with the approved bacterial plasmid *pCRI*. When 0.8 μg of hybrid molecules were used to transform *E. coli* strain κ1776 we obtained 112 independent transformed clones (that is, cells which had received the kanamycin resistant phenotype conferred by *pCRI*).

As expected, not all of these 112 clones contained immunoglobulin sequences. These 112 clones were grown on nitrocellulose filters, and hybridised to highly purified ¹²⁵I-labelled

Table 1 Extent of hybridisation of MOPC-149 cDNA to various plasmid DNAs

Unlabelled sequences	MOPC-149 ³ H-cDNA S1-nuclease resistant c.p.m. (%)
<i>pCRI-κ40</i>	135 (66)
<i>pCRI-λ52</i>	21 (10)
<i>pCRI</i>	32 (16)
MOPC-149 mRNA	209 (100)

Full-length, purified ³H-MOPC-149 cDNA was hybridised to an excess of unlabelled plasmid DNA, and the amount of hybrid formed was measured as the amount of S1-nuclease resistant material formed during hybridisation²⁵. The plasmid *pCRI-λ52* was constructed in the same fashion as plasmid *pCRI-κ40*, except that total poly A-containing mRNA from the myeloma tumour RPC-20 was used to make the initial cDNA transcripts. 200 c.p.m. of MOPC-149 cDNA was added to 0.5 μg sonicated plasmid DNA or 20 ng of MOPC-149 mRNA, in 0.6 M NaCl, 50 mM Tris pH 7.5, in a final reaction volume of 50 μl. The samples were boiled, placed at 70 °C and allowed to hybridise for 2 h. Finally, the samples were diluted into 1 ml of S1-nuclease buffer (0.04 M NaCl, 0.03 M sodium acetate pH 4.5, 0.12 M ZnSO₄) divided into two equal portions and one portion was digested with 5 μl S1-nuclease for 1 h at 45 °C. The number of trichloroacetic acid-precipitable counts remaining after S1 digestion was taken as a measure of the amount of hybrid formed.

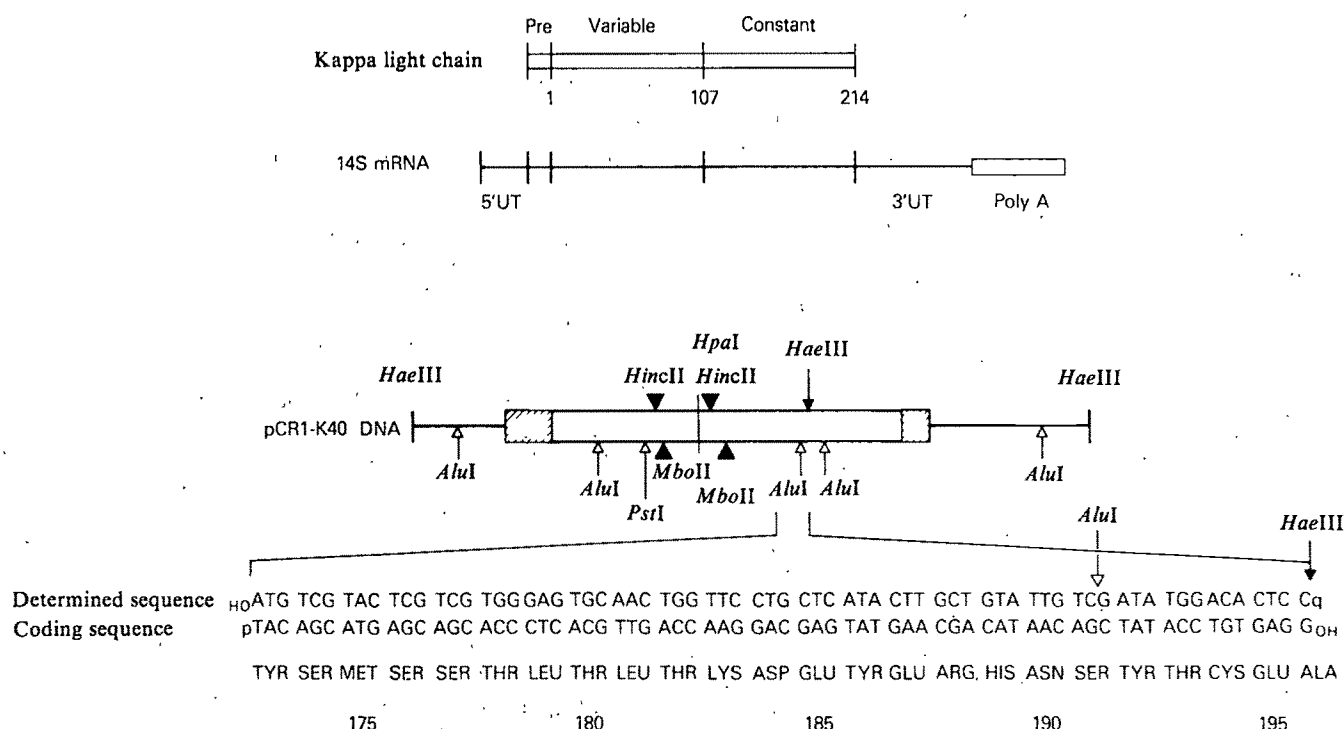

Fig. 3 The arrangement of the immunoglobulin light-chain gene sequences inserted into pCR1- κ 40 and the location of restriction enzyme sites in the inserted sequence. Kappa light chain represents a single polypeptide (amino terminus left; carboxyl terminus right) formed during *in vitro* translation of 14S immunoglobulin mRNA. The polypeptide has been divided by vertical lines into three regions, a 20-amino acid putative precursor sequence, a 107-amino acid variable region sequence and a 107-amino acid constant region sequence. The numbers below the vertical lines indicate the amino acids at the ends of the variable and constant regions. 14S immunoglobulin light-chain mRNA, drawn with its 5' end at the left, is roughly 1,200 bases long (including about 200 bases of poly A at the 3' end). The regions directly below the variable and constant regions of the light chain represent the two 321-base sequences required to encode these portions of the polypeptide. 5' UT and 3' UT are the parts of the mRNA which are not translated into protein, and are found near the 5' and 3' ends of the mRNA. The pCR1- κ 40 DNA segment shown includes the insert sequence, as well as the plasmid sequences (represented by a straight line) and the poly dA-T linkers (cross-hatching) that join the insert to the plasmid. The determined nucleotide sequence (see Fig. 2) was found to be from the anti-sense strand. The coding sequence, deduced from the anti-sense sequence, was found to correspond to amino acids 173-196 of the constant region (bottom row). Most of the restriction enzyme sites, (*Pst*I, one *HincII*/*Hpa*I, one *Mbo*II, and one *Alu*I site) were determined by digesting the 325-base pair fragment or the 525-base pair fragment, obtained by *Pst*I cleavage of the kinase-treated 850-base pair *Hae*III fragment, with each enzyme. Similar multiple enzyme digests using kinase-labelled fragments were used to identify the other indicated cleavage sites. *Mbo*II, and *Alu*I each cleave the insert sequence in at least one more location, but these locations have not been defined. We have noted that the deduced sequence contains a *HincII* recognition sequence (at the sequence encoding amino acid 178/179), however while some evidence for partial cleavage at this site has been found, the enzyme prefers the other two sites at least threefold.

14S mRNA obtained from MOPC-149 myeloma tumours using the procedure of Grunstein and Hogness³¹. Sixteen of the 112 clones hybridised to purified mRNA (data not shown). The DNAs from these 16 clones were then screened for their ability to protect highly purified MOPC-149 cDNA from S1-nuclease digestion. For example, the DNA from pCR1- κ 40 was able to protect 66% of a MOPC-149 cDNA from S1-nuclease digestion (Table 1). pCR1- κ 40 DNA protected more MOPC-149 cDNA than the DNAs from any of the other 15 clones, so this clone was chosen for further analysis.

One problem with the poly dA-T joiner method is that insertion of a sequence at the restriction endonuclease *Eco*R1 cleavage site within the plasmid DNA destroys the *Eco*R1 site. Thus the insert sequence cannot be cleanly excised from the plasmid DNA by the action of a single restriction enzyme. To overcome this problem Weissman and co-workers²⁵ have developed a technique which cuts the poly dA-T joiner sequences and excises the insert sequence as a single fragment. As poly dA-T has a lower melting temperature than any other sequence, these sequences can be preferentially denatured in 40% formamide. These sequences are then susceptible to S1-nuclease digestion. The fragment excised in this way can be separated from the rest of the plasmid DNA by gel electrophoresis. The results of such an experiment performed on pCR1- κ 40 DNA are shown in Fig. 1a. Two fragments are excised from

pCR1- κ 40 DNA, but not from pCR1 DNA. Both of these fragments specifically hybridise to MOPC-149 cDNA (Fig. 1b). We suggest that the fainter, slower band is a partial digestion product, reflecting the presence of an easily denatured sequence in the plasmid pCR1. We believe that the faster-moving fragment, present in high yield, contains the insert sequence free of any plasmid sequences. The size of the inserted sequence seems to be 700 ± 50 base pairs. Consistent with this result was the finding that the R loop²⁶ formed between pCR1- κ 40 DNA and MOPC-149 mRNA was about 700 base pairs long (J.G.S., M. Sullivan, and B. Peterlin, unpublished).

The sequence inserted into pCR1- κ 40 is only 700 ± 50 bases long whereas immunoglobulin mRNA (not including the poly A) is 950 bases long, indicating that about 200 bases of light-chain mRNA sequences must be missing from the cloned sequence. Which portions of the mRNA are not included in the inserted sequence in pCR1- κ 40? To answer this question, and in order unambiguously to identify the cloned segment, we identified the restriction endonuclease cleavage sites in the inserted sequence, determined the nucleotide sequences around these cleavage sites, and then correlated the nucleotide sequences with the amino acid sequence which they encode.

We have found six restriction endonucleases that cleave the inserted sequence in pCR1- κ 40. pCR1 and pCR1- κ 40 DNA were digested with many restriction enzymes and electro-

phoresed on polyacrylamide or agarose gels; enzymes with cleavage sites in the insert sequence showed at least one more band in the pCR1- κ 40 digests than in the pCR1 digest. These results were confirmed by blotting the fragments onto nitrocellulose paper and hybridising to ^{32}P -labelled MOPC-149 cDNA as described by Southern²⁷. If an enzyme cleaved the insert sequence then label would hybridise to two bands rather than just a single band. In this way the restriction enzymes *Mbo*II, *Alu*I, *Hae*III, *Hpa*I, *Hinc*II, and *Pst*I were each shown to cleave the inserted sequence at least once, while the enzymes *Bam*HI, *Hind*III, *Hha*I, *Sst*I, *Hinf*I, *Hae*II, *Hpa*II, *Kpn*I and *Bgl*II do not seem to cleave the inserted sequence.

The nucleotide sequence of a small portion of the inserted sequence in pCR1- κ 40 was determined in order to demonstrate conclusively that the inserted sequence could encode for a portion of light-chain amino acid sequence. An 850-base pair fragment from a *Hae*III digest of pCR1- κ 40 DNA was isolated, labelled at its 5' ends with ^{32}P , cleaved into two pieces (a 525-base pair fragment and a 325-base pair fragment) with *Pst*I (see Fig. 3), and finally the 325-base pair fragment was subjected to the standard reactions for sequencing DNA fragments of Maxam and Gilbert³⁰ (Fig. 2). The nucleotide sequence determined from this procedure is shown in Fig. 3. This nucleotide sequence when read in the correct frame correlates perfectly with a 23-amino acid sequence from the immunoglobulin kappa-type constant region, and with the RNA sequence predicted by Milstein *et al.*²⁸. Thus, we conclude that an immunoglobulin sequence has been inserted into pCR1- κ 40. Using this nucleotide sequence to orientate the map we were able to determine the arrangement of immunoglobulin sequences in pCR1- κ 40 (Fig. 3). Further, the plasmid pCR1- κ 40 contains about 700 base pairs of the immunoglobulin gene sequence, spanning a portion of the 3' untranslated region, the entire constant region and over 150 base pairs of MOPC-149 variable region gene sequence.

This hybrid molecule will be of great value for nucleotide sequence analysis, identification and cloning of genomic DNA segments containing actual immunoglobulin genes and the unambiguous determination of their arrangement in chromosomal DNA. Indeed, we have already used pCR1- κ 40 to obtain two interesting chromosomal DNA fragments containing immunoglobulin variable region sequences (J.G.S., M.H.E., D. Tiemeier, S. Tilghman, F. Polsky, A. Leder, P.L., unpublished).

Corrigendum

In the letter 'Detection of casein messenger RNA in hormone-dependent mammary cancer by molecular hybridisation' by J. M. Rosen & S. H. Socher, *Nature* **269**, 83-86, the legend to Fig. 4 should start 'Measurement of casein mRNA in hormone-independent mouse mammary tumours. . . .' (not hormone-dependent). Similarly, line 2 on page 86 should read '. . . in the hormone-independent mouse mammary carcinomas . . .'.

Errata

In the letter 'Birefringence signals and calcium transients in skeletal muscle' by G. Suarez-Kurtz & I. Parker, *Nature* **270**, page 748, the horizontal calibration in Fig. 3a should read 50 ms, not 10 ms.

In the letter 'Circular structures of large scale and great age on the Earth's surface' by J. M. Saul, *Nature* **271**, 345-349, Figs 1 and 2 were reproduced to the wrong scale so that the transposition marks do not correspond. The scale reduction of 1:1,000,000 in Fig. 1 legend is also incorrect. The correct versions of these figures can be obtained in reprints of the letter.

Nature Index and Binders

The complete Index for 1976 is available, price £2.50 (UK), US\$5.00 (Rest of World). Copies of the 1975 index are still on sale, price £2.25 (UK), US\$5.00 (Rest of World).

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

matters arising

Biostratigraphy of Seymour Island, Antarctica

THE paper by Hall on Cretaceous and Tertiary dinoflagellates from Seymour Island, Antarctica¹ contains misleading information. In particular, the stratigraphic columns in Fig. 1 do not represent the known field relations. The overlap of sections S-13 and S-3 seems most unlikely on geological grounds; the sections are less than 3 km apart, the sediments have different provenances, and represent different facies (S-13 is delta plain, and the lower part of S-3 is prodelta or delta slope, and palaeo-current indicators suggest southeastward flow). The base of the measured section S-3 is not the base of that part of the sequence. Section S-11 occurs below the unconformity above which S-13 is located; the Palaeocene age may well be correct, but there is no overlap in time with S-13. The age of the beds at Cape Wiman (S-16) is open to debate, but the correlation indicated in Fig. 1 is an oversimplification of the possible interpretations.

The ammonite-dated strata form part of a homoclinal sequence dipping to the south-east and occupying the whole of the southern half of Seymour Island. Howarth² figured several ammonites from near the base of the section, and one ammonite from near where the unidentified ammonite was found that contains 'early Senonian' dinoflagellates in the matrix. Howarth assigned an Early to Middle Campanian, or possible late Campanian age, to the ammonites he described. The strata from which the 'unidentified' ammonite comes are unconsolidated, so that fossils are found, with few exceptions as loose material on dip slope surfaces or at the base of short sections. The ammonite was collected on a dip slope. The southern half of Seymour Island, unlike the northern part north of Cross Valley, lacks glacial debris, and therefore the ammonite cannot be considered a glacial erratic. The 'unidentified ammonite' belongs to the genus *Maorites*, is identified specifically as *M. densicostatus* (Kilian and Reboul), and others of this species are figured by Howarth². Hall's postulate of an 'early Senonian' age seems to be in conflict with the ammonite data. Until proven otherwise, the most likely explanation of this apparent conflict is that the dinoflagellates had been

reworked from older strata or, as stated by Sarjeant³, that the exact ranges of these dinoflagellate species are uncertain.

Finally we would note that Simpson⁴ regards the so-called Miocene beds as Late Eocene, though possibly either Middle Eocene or Early Oligocene. Furthermore, Von Ihering³ recognised the Eocene affinities of the molluscs.

Hall's data are very valuable, but some of the statements and conclusions are misleading for those not familiar with the local geology. Papers on the stratigraphy and palaeontology of the Tertiary rocks on Seymour Island have been presented at the Third Symposium on Antarctic Geology and Geophysics at Madison, Wisconsin, in August, 1977.

DAVID H. ELLIOT
WILLIAM J. ZINSMEISTER

*Institute of Polar Studies,
Department of Geology and
Mineralogy,
The Ohio State University,
Columbus, Ohio 43210*

HALL REPLIES—In 1975 I examined sediment samples from four measured sections on Seymour Island, Antarctic Peninsula in a pilot study of dinoflagellates, spores, and pollen. A series of palynologic assemblages from two sections, S-3 and S-11, contained numerous diagnostic dinoflagellates; the sections were provisionally assigned a late Eocene-early Oligocene age and a Palaeocene age, respectively. However, sections S-13 and S-16, the correlations of which Elliot and Zinsmeister are critical, are represented collectively only by three samples. Concerning age dating, I reported that "neither of the samples from S-13 provides conclusive information". I also suggested a Palaeocene or late Cretaceous age for S-16 based on one dinoflagellate assemblage. Not only did I report the unsureness of the correlations of S-13 and S-16, but question marks were drafted adjacent these sections in Fig. 1 of ref. 1, further stressing the uncertainty of the correlation of these two sparsely sampled sections. The correlations shown in the figure that are misleading to Elliot and Zinsmeister are clarified on reading the text of the article.

The dinoflagellate species *Cyclonephelium distinctum* and *Deflandrea cretacea* have greater ranges than I acknowledged in the article. Thus my

age assignment of 'early Senonian' to the ammonite matrix (unidentified when I submitted the manuscript but subsequently referred to *Maorites densicostatus*) is indeed unwarranted.

Elliot and Zinsmeister cite Simpson's⁴ review of fossil penguin material and Von Ihering's³ 1927 molluscan studies from Seymour Island as previous interpretations of an Eocene age for these beds, an implied criticism that my corresponding conclusion based on dinoflagellates is less than original. I give Simpson full credit for his conclusions in my article: "The dinoflagellates evidence supports Simpson's conclusion that the fossil penguin materials from Seymour Island, presumably from the upper part of section S-3 or its equivalent, are no older than late Eocene and no younger than early Oligocene". Von Ihering's fortuitous interpretation in 1927 of an Eocene age for the Seymour Island Series was disputed by Antarctic scholars for over 40 yr; the beds were regarded as Miocene in age⁴ until Simpson's vertebrate work and the supporting evidence of the dinoflagellates.

Asymmetrical displacement currents

KOSTYUK *et al.*¹ have recorded an asymmetrical displacement current in snail neurones (*Helix pomatia*) which, because of a similar voltage dependence, they have associated with the calcium conductance change caused by membrane depolarization. It was noted that the characteristics of the 'calcium gating currents' in snail¹ and *Aplysia*² neurones were different, and it was suggested that at least part of the difference was due to a technical problem with series resistance. However, we think that there are indeed actual differences in the displacement currents recorded in the two neurones.

First, in voltage-clamp studies in snail neurones, it has not been possible to demonstrate separate channels with

different kinetics or voltage dependence for sodium and calcium ions³⁻⁵. Consequently the displacement current recorded in snail neurones¹, although sharing the voltage dependence of calcium ionic current, may be associated with gating of sodium channels, gating of calcium channels, or gating of common channels through which both sodium and calcium ions can pass. In contrast, separate, distinguishable channels for sodium and calcium ions have been demonstrated clearly in *Aplysia* neurones because of differences in kinetics and voltage dependence^{2,6}. Thus a displacement current with properties (particularly voltage dependence) similar to those of the calcium conductance change, but distinct from those of the sodium conductance change can reasonably be called a calcium gating current. If the displacement current recorded in snail neurones¹ is not gating channels selective for calcium ions, as seems possible, it could well be different from the calcium gating current in *Aplysia* neurones.

Second, we believe that the slow rising phase of the calcium gating current recorded in *Aplysia* at 6°C is real and not due to slow establishment of a new clamp potential, as suggested by Kostyuk *et al.*¹, for the following reasons. (1) As we have stated², new clamp potentials were reached within 100 μ s. (2) The measured series resistance was always less than 0.5% of the membrane resistance. We have calculated that the time constant of the change in membrane potential across the surface membrane would be less than 100 μ s. (3) The rising phase of the calcium gating current is preceded by an 'immediate on, exponential off' asymmetrical displacement current which we believe is sodium gating current for the reasons given². If the slow rising phase of the following calcium gating current were due to slow establishment of the clamp potential, the time course and voltage dependence of the earlier displacement current would be difficult to explain. (4) The time to peak of the calcium gating current has a high Q_{10} of about 3. This temperature sensitivity can hardly be due to slow establishment of new potential levels across the surface membrane. (5) The time to peak of the calcium gating current can be varied by changing the holding potential while keeping the clamp step amplitude constant, again difficult to explain in terms of slow clamping.

We must conclude therefore that the slow rise of calcium gating current we have recorded in *Aplysia* neurones² is real and cannot be explained as suggested by Kostyuk *et al.*¹ If the displacement current recorded by

Kostyuk *et al.*¹ is indeed a true calcium gating current, there may be real differences in calcium gating currents in the surface membranes of the two nerve cells.

3. Kostyuk, P. G., Krishtal, O. A. & Doroshenko, P. A. *Pflügers Arch. ges. Physiol.* 348, 83-93 (1974).
4. Standen, N. B. *J. Physiol., Lond.* 249, 253-268 (1975).
5. Lee, K. S., Akaike, N. & Brown, A. M. *Nature* 265, 751-753 (1977).
6. Geduldig, D. & Gruener, R. J. *Physiol., Lond.* 211, 217-244 (1970).

KOSTYUK *et al.* REPLY—Adams and Gage have suggested several additional arguments in favour of the existence of a rising phase in the development of Ca gating current recorded in the neurone of *Aplysia*. But they do not consider the problem of membrane potential settling time in the two microelectrode voltage clamp experiments. They say that the "control of membrane potential . . . was achieved in less than 100 μ sec". But the rapid changes of potential measured at the microelectrode input can strongly differ from the real (and much slower) changes in the membrane potential. This difficulty in microelectrode voltage clamp experiments has been mentioned by Geduldig and Gruener² in their investigation of *Aplysia* neurones. It is due to the existence of a capacitance between closely situated microelectrodes used to measure potential and inject feedback current. Detailed analysis of the corresponding circuit is quite complicated (some useful information can be found in ref. 3). The settling time of a new clamp potential can be estimated from the termination of current capacitive transient only. The membrane current curves demonstrated in Fig. 1 by Adams and Gage¹ (although presented on a contracted time scale) suggest that the capacitive transient in these experiments lasted for several ms. The time-to-peak of the asymmetrical current presented in Fig. 3 is in qualitative agreement with that length.

These arguments are not intended to question the relationship of the recorded asymmetrical current¹ to the movement of gating charges. But it seems likely that the rate of decay of the 'early' component and the delayed rising phase of the 'late' component reflect the conditions of the experiment rather than the real kinetics of gating currents. Other effects suggested as

arguments in favour of the 'natural' origin of the rising phase can also be explained in another way. Thus the cooling of the preparation results in an increase in membrane resistance. It is equivalent to an increase in the internal resistance of the current source which charges the membrane capacitance.

The discovery of a true rising phase in the gating current would be very important for the description of gating charge movement⁴. But the experimental problems of sufficiently fast membrane potential settling are difficult to solve and must be treated cautiously⁵. As to the separation of specific Na and Ca channels in molluscan neurones, this was achieved recently with the help of the intracellular dialysis technique⁶.

Multispecific antibodies

VARIOUS points were raised by Secher¹ in a comment on our recent letter on "Evidence for multispecificity of antibody molecules²."

One question concerned the biological significance of cross reactions having binding constants of about 10^3 l mol⁻¹. We showed that these cross reactions will fix complement and lyse red cells²; one can conclude that if they can induce cytolysis, they are likely to be of biological significance. On the other hand, the concentration of antibody (and target antigen) has an important role. If one assumes a titre of 150 μ g ml⁻¹ of IgG (that is, 10^{-6} M) and, for simplicity, a similar one for the antigen (although if it is on a cell membrane one really cannot make an estimate), then, for a binding constant of 10^3 l mol⁻¹, about 10% of the antibody will be in the bound form. This is a conservative estimate since it has been shown^{3,4} that the 'functional' affinity is larger by a factor of 10^3 to 10^4 than the association constant for the binding of a monovalent hapten. The binding interaction would be even more favoured if the antigen were concentrated in a particular area, for example, bacterial antigens in a local infection, or, as in the case of putative autoimmune diseases, antigenic structures on tissues and organs.

Secher calls our analogy between antibodies and enzymes "not very appropriate" because "enzymes are homogenous and so multispecificity in substrate binding could not enhance their specificity . . .". Perhaps we were unclear in our paper. We were not trying to draw a functional analogy but were trying to indicate that all protein-ligand interactions rely on the same play of short range forces and geometry. Hence, if enzymes are multispecific, it should not be surprising to find that antibodies are also multispecific.

We should like to comment also on Secher's suggestion that the best antibodies (with binding constants of 10^9 – 10^7 mol⁻¹) may be highly specific (that is, not multispecific). From our point of view, this is not a logical conclusion. Whether a binding constant for a ligand is 10^9 mol⁻¹ or 10^6 mol⁻¹, the character of the binding site of the antibody is no different. It still should be able to accommodate other ligands and interact with them. Presumably the binding constant of a cross reaction could be even higher than that of the reaction with the immunogen.

We should like to thank Secher for reminding us of the early suggestions of Talmage⁵. We are embarrassed by our failure to cite his paper.

SECHER REPLIES—Enzymes (and antibodies) can bind ligands (antigens) other than the 'primary ligand'. Ligands with very similar chemical structure may bind almost as tightly as the main ligand and one might expect to find a series of compounds of decreasing association constant and decreasing chemical similarity to the primary ligand. The concept of multispecificity (as used by Inman for example) is different. It implies that two or more antigens of unrelated structure can bind specifically to a single antibody molecule. This could take place at distinct sites, overlapping sites, or the same site, but presumably will use different contacts between the antibody and the antigen.

The former phenomenon is well known for both enzymes and antibodies. However there are only a few claims of examples of multispecificity

(in both systems), and even these are controversial.

With reference to the specific points that Cameron and Erlanger raise above. Binding of antigen is only one aspect of the biological significance of a cross-reaction. The ability to trigger lymphocytes into division and antibody production must also be considered, and also the extent to which such cross-reactions are representative of the total antibody population or are rare exceptions.

I agree that if "enzymes are multispecific then it should not be surprising to find that antibodies are also multispecific". To what extent these generalities have been demonstrated is still not clear (see above for definition of multispecificity).

The final sentence of my original article was intended to be taken as pure speculation and not as a logical conclusion.

Cross-reactions with binding (association) constant higher than that of the immunogen do indeed exist and have been named 'heteroclitic'.

(An error in my original article has been corrected²).

Marsupial trophoblast and mammalian evolution

We present here a view of marsupial-eutherian origins and evolutionary trends, which constitutes an alternative to the view of Lillegraven^{1,2} recently discussed by Cox in a *Nature News and Views* article³.

The trophoblast constitutes the outer foetal boundary of the eutherian chorioallantoic placenta where it functions as the major foetal component of the placental barrier as well as a site of endocrine activity. The trophoblast is also a foetal component of the eutherian yolk sac placenta. In most marsupials, maternal-foetal transfers occur solely through a yolk sac placenta where trophoblast associates with both vascular and avascular regions. An important exception occurs in the marsupial bandicoots where both yolk sac and chorioallantoic placentae develop; trophoblast differs in form regionally within the boundaries of each type of placenta⁴⁻⁶.

The trophoblastic layer persists until term in the chorioallantoic placenta of all mammals except bandicoots, in which the layer disappears shortly before term⁴⁻⁶. Lillegraven, however, states (page 713, ref. 2) that "tropho-

blast is strictly found only in placental mammals," thus misquoting his authorities, Davies and Hesseldahl, who say that trophoblast is a peculiar mammalian structure. Lillegraven (page 720, ref. 2) states further that "The 'invention' of trophoblastic tissues by primaeval eutherians was probably the single most important evolutionary event in the history of the infraclass". This has led to the mistaken conclusion that it is the evolution of trophoblast which enables only Eutheria to obviate immunological crisis during pregnancy^{2,3}.

Lillegraven says (page 101, ref. 1) that "... true implantation by erosion of the maternal epithelium never occurs in marsupials". It has long been known that in the bandicoot chorioallantoic placenta trophoblast disappears as a layer late in gestation⁴⁻⁶, probably through fusion with the uterine luminal epithelium⁶. Comparable fusion may also occur during early implantation of certain Eutheria⁶. Similar, less extensive invasion of uterine epithelium by trophoblastic cells occurs at the yolk sac placenta in several marsupials (such as in *Dasyurus viverrinus* and *Sminthopsis crassicaudata*), the uterine epithelial layer becoming modified at the placental site by interaction of foetal and maternal tissues during implantation.

Thus, evidence concerning trophoblast and uterine erosion tends to unite rather than separate evolutionary aspects of eutherian and marsupial placentation. Although it is not known whether marsupial trophoblast contains immunological or endocrine properties comparable with those proposed for eutherian trophoblast⁷, attention is being focused on this important problem⁸. Because trophoblast is certainly not a eutherian innovation, the argument for the "competitive inferiority" of marsupials is considerably weakened, as Kirsch⁹, on other grounds, has also concluded.

reviews

Bridging the two cultures

Eric Ashby

A Sense of the Future. By J. Bronowski. Pp. 286. (Massachusetts Institute of Technology Press: Boston, Massachusetts and London, 1977.) \$12.50; £7.25.

JACOB BRONOWSKI was one of those rare people who deserve the title of "Renaissance Man". Academics are suspicious of Renaissance Men. A mathematician who can write perceptively about Blake, compose a play, publish poetry which isn't doggerel, and do research ranging from the history of ideas to the technology of coal: such a man must surely be "unsound". But for this prejudice among pedants, Bronowski would surely have been taken more seriously than in fact he was. No doubt there are better coal technologists, better poets, better literary critics, better philosophers, than Bronowski was. The value of his contribution to contemporary thought rests upon his capacity to see the relationships between these disciplines, to create patterns in which the disciplines are intertwined. This is what he did in *Science and Human Values* and in *The Identity of Man*. (It is significant that both these books are based on lectures he gave in the USA: Americans are more hospitable to Renaissance Men than the British are.) And his television series, *The Ascent of Man*, was a heroic attempt to achieve his ambition: "to create a philosophy for the twentieth century which shall be all of one piece". He drew his viewers into participation over questions which have perplexed intellectuals for a millennium.

Anyone who writes and talks as fluently as Bronowski did is saturated with invitations to contribute articles and to give lectures. Characteristically, Bronowski generously accepted many of these invitations and took immense pains to make his contributions elegant and polished. In *A Sense of the Future*, nineteen of these, covering the years 1952 to 1974, have been selected and edited for publication. They comprise his reflections on science. Another volume is promised, which will contain his reflections on aesthetics and literature.

The themes of these essays are familiar to those who have read Bronowski's books. He generates a

Jacob Bronowski

stream of traffic across the bridge between the Two Cultures (a bridge which, oddly enough, C. P. Snow seems never to have discovered). In science, he says, the experiment conceived in imagination is tested by confronting it with physical experience; in literature, the imaginative conception is tested by confronting it with human experience. Experiments and conceptions which survive become part of the cultural heritage. In science, as in humanism, excellence depends on the quality of imagination. In the pursuit of science Bronowski sees also the recipe for ethics; for to pursue science is to search for truth, and no one can verify for himself all the truths he needs to know. Therefore, he has to trust the word of other people. Therefore, the principle of truthfulness "binds society together, because without it the individual would be helpless to tell the truth from the false"; it is a cement to hold society together. So his "social axiom" is that we ought to act in such a way that what is true can be verified to be so.

The most thoughtful essays in the book are about evolution. Bronowski expounds with admirable clarity the

difference between the 'closed' teleology of (say) a watch, whose purpose is implicit in the way its parts are put together, and the 'open' teleology of evolution, where there is selection for 'fitness for change' to meet unpredictable changes in the environment. Of evolution, Bronowski writes, we can say "what Piet Hein said of a work of art, in a penetrating phrase: that it solves a problem which we could not formulate until it was solved".

It is commonly assumed that people who write and lecture fluently possess an inexhaustible reservoir of fresh ideas. This assumption, even for the Bronowskis of this world, is incorrect. Therefore, when they are pressed with invitations to talk here and to write there, they either have to appear churlish, and refuse, or they have to cannibalise some of their own earlier work. So I'm not surprised that there is some repetition in these essays, between chapters 7 and 8, 9 and 10, 12 and 13, 15 and 16. If Bronowski himself had edited these essays, I guess he would have chosen one or the other, not both, of these overlapping pairs. His editors may be criticised for not having done this. I am grateful for the repetitions. They reveal how unsolved problems lodged in Bronowski's mind for years, to be taken out and re-examined from time to time. It is instructive to watch him reflecting on the same subtle idea (for instance, the *Entscheidungsproblem* which he first encountered as an undergraduate in 1931) in two essays, one written in 1966 for the *American Scientist*, and the other eight years later in a symposium on the philosophy of Karl Popper.

Opinions about this book will depend upon the spirit in which it is read. It tackles the most intractable of all philosophical problems: the relation between objective truth as a scientist sees it and subjective consciousness as a man feels it in himself. Those who look for a solution to this problem will, of course, not find it. Those who relish every thoughtful re-examination of this problem will appreciate the elegance with which it is presented. In brief, it is a book to be read not so much for instruction as for delight. □

Lord Ashby is Chancellor of the Queen's University, Belfast, Northern Ireland.

Point defects in solids

Defects in the Alkaline Earth Oxides. By B. Henderson and J. E. Wertz. Pp. 152 (Taylor and Francis: London, 1977.) £8.50.

THIS monograph is concerned mainly with the structure and properties of point defects studied primarily by the techniques of optical and paramagnetic resonance spectroscopy, a field of investigation to which the authors have themselves made significant contributions during its development over a period of nearly 20 years.

MgO and CaO have been extensively studied, the other oxides less so. Transition metal impurities occupy substitutional sites, sometimes in association with nearby impurity or defect sites, and detailed tabulations of data are given. Whereas early studies were often complicated by the unwanted presence of impurities, it has much more recently become apparent that impurities can play an important part in moderating the production of lattice defects by particle irradiation. The structure of anion vacancy defects

seems to be very well understood, although the interpretation of observations relating to cation vacancy defects still presents some problems. The power of double resonance techniques, both ENDOR and those involving simultaneous irradiation at optical and microwave frequencies, is beautifully illustrated. Compared with the extensive array of experimental results on anion and cation vacancy defects, the information available about point interstitial defects is still sparse.

The appearance of this review is timely as the subject has reached that stage of maturity at which a perspective view of the considerable amount of published work is of real value both as a summary of achievement and as an aid in directing attention to the nature of the most significant problems which remain to be solved. The selection of material is well balanced and concisely presented, and will serve not only as a useful compendium for those engaged in this field but also as a helpful guide and introduction for the newcomer.

Electrochemical techniques

Electrochemistry of Biological Molecules. By Glenn Dryhurst. Pp. xii+601. (Academic: New York and London, 1977.) \$47; £33.35.

POLAROGRAPHY was invented in 1922 and soon became an important method of chemical analysis. At the end of the 1950s, there was a decline in the practical everyday use of this method, because direct current (d.c.) polarography, particularly its sensitivity, no longer met the demands then being made on modern analytical methods. Recent years have seen, however, a renaissance in polarographic and voltammetric analyses, and from classical d.c. polarography a number of modern electrochemical techniques have been derived. Of these, derivative (differential) pulse polarography has surpassed d.c. polarography in sensitivity by about two orders of magnitude, and has become increasingly applied to biological research. The publication of Dryhurst's book is therefore timely.

The content of this book covers a narrower research area than that suggested in the title. Of the compounds with biological significance, only nitrogen heterocycles are included. Electrochemistry is mainly limited to the

studies of these substances using polarography and related techniques. The introductory chapter summarises the theory and instrumentation of electro-analytical measurements in a way that will be easily understood even by readers with no experience of electrochemistry. Further chapters contain information on electrochemical reduction and/or oxidation of N-heterocycles, including purines, pyrimidines, pteridines, flavines, pyrroles, porphyrines and pyridines.

About 250 pages are given over to nucleic acids and their constituents. Although the electrochemical reduction of nucleic acid constituents and their analogues has already been studied in considerable detail (there is also quite a vast literature on purine oxidation), more detailed research on the electrochemical behaviour of oligonucleotides is still needed, representing the missing link between studies of polynucleotides and their monomeric units. Nevertheless, research on nucleic acid structure and properties using electrochemical analysis has developed rapidly in recent years. A correlation between the reducibility of nucleic acids in solution and their conformation is the basis for the application of polarographic techniques to the investigation of small changes in DNA double-helical structure. Changes in nucleic acid reducibility can also serve as an indication of conformational changes occurring in nucleic acids adsorbed at interfaces.

On the other hand, literature concerning oxidation of polynucleotides is as yet practically non-existent.

Included in the book are more than 1100 references, from which an impressive amount of electrochemical data has been extracted. This monograph is an invaluable source of information for electrochemists; it will probably also be useful to biochemists

and biologists interested in properties of biologically important N-heterocycles and their analogues.

European pollen flora

The North-West European Pollen Flora. Vol. 1. Edited by W. Punt. Pp. 145. (North-Holland: Oxford, New York and Amsterdam, 1977.) \$19.95; Dfl.50.

PALYNOLOGY, the study of pollen grains, is proving to be a valuable technique in a variety of disciplines, particularly environmental ones, both ancient and modern. The recognition of subfossil pollen permits the reconstruction of past vegetation and the detection of palaeo-environmental changes, and the monitoring of present-day pollen fall-out is a necessary part of allergy research. Melissopalynology, the study of pollen in honey, permits the identification of the flowering plants visited by bees.

The rapid growth of these subjects has led to a considerable demand for manuals of palynological techniques and also for data regarding the precise identification of pollen types. At present, the published studies of pollen taxonomic research are widely scattered in the literature and some families have received little attention. This book, and those which will follow it in this series, is designed to remedy this deficiency and to provide an accessible and up-to-date collection of pollen morphological studies. This is being tackled by commissioned review articles which are published in the journal, *Review of Palaeobotany and Palynology*, and which are then collected together in what will be a series of books concerning North-West European pollen.

Obviously, some families are smaller or morphologically less complex than others, so the order in which the published accounts will appear is rather unpredictable. The first collected volume contains accounts of the Caprifoliaceae, Primulaceae, Adoxaceae, Sparganiaceae, Typhaceae, Gentianaceae and Guttiferae. All except for the last of these have been written by members of the Laboratory of Palaeobotany and Palynology of the State University, Utrecht, Netherlands. The account of the Guttiferae is by G. C. S. Clarke of the British Museum (Natural

History).

Each family is divided into a series of "pollen types". The use of the term "type", however, departs from the convention normally adopted in palynological studies, in which "type" is used only when a number of taxa are indistinguishable on the basis of their pollen. Here, a pollen type may contain only a single species which makes the term "type" somewhat redundant. Keys are provided to the pollen types within each family, and full descriptions of the pollen morphology are given. The descriptive terminology of Reitsma is used throughout, which is commendable, for this provides a more consistent and logical system than the earlier ones of Erdtman, and Faegri and Iversen. The descriptions are very full, though it might have been valuable to have added the shorthand designation devised by Iversen and Troels-Smith. Size measurements are given for grains mounted in both glycerol jelly and in silicone oil, which is useful since both of these media are extensively used. One feature which leads to a certain degree of concern is that the descriptions are based upon a very limited number of collections. Some of the types are described on the basis of just one or two collections, and these can hardly be expected to display the full potential range of variation within the taxa.

Excellent collections of photographs are included with each account. These are based upon light field, phase contrast and scanning electron microscopy. They provide extremely valuable supplements to the pollen descriptions. The plates would be far simpler to use if the legends were included on them rather than preceding them. This may seem a minor criticism, but it does limit the speed and efficiency with which the plates can be consulted.

This series will undoubtedly prove to be the definitive work on the pollen of north-west Europe for many decades and one must congratulate the authors, editors and publishers on the production of a most valuable and useful book. I look forward to the appearance of further volumes in this series.

Edward Arnold
25 Hill Street,
London W1X 8LL

al edited by
Diamond Gil-
millan: Lon-
stoneh
p. viii
1977.) At two substantial
titles but differ-
of authors have
this subject in 1977.
by Stonehouse and
very largely with
marsupials, and 28 of the
have studied marsu-
Australia and New Zealand.
the editors' hope that the
"should form an introduction to
research on this long-neglected
fascinating group of mammals"
is a laudable one, only about half the
contributors have attempted to do this
by reviewing their particular field.
These chapters are all useful and some
are excellent.

Clemens' chapter provides an over-
view of current theories of marsupial
origins and relationships to other
therian groups. His conclusion that
most land masses could have been in-
habited by primitive therians in the
early Cretaceous, any one of which
could have been the site of origin of
marsupials and placentals, is provoca-
tive, as it allows for a reversal of the
conventional view of origin in North
America and a southward spread in
the late Cretaceous and Tertiary.

Hayman reviews the field of mar-
supial karyology from a much firmer
data base. The chromosomes of mar-
supials are better known than for most
of the orders of mammals and under-
standing of the evolution has reached
an advanced stage which this chapter
reviews.

The functions of the adrenal cortex
of marsupials are admirably reviewed
by McDonald, while Setchell has
written a wide ranging, scholarly ac-
count of reproduction in male marsu-
pials, a field hitherto often neglected.

Of the ecological chapters, that by
Lee, Bradley and Braithwaite on the
resolution of the unique phenomenon
of synchronous mortality of male
Antechinus is fascinating as a piece of
problem solving by a coordinated group
with several different skills, while
Parker's more theoretical chapter, de-
serves special mention as the first
serious attempt to compare the eco-
logical consequences of marsupial and
eutherian reproductive strategies. Her
conclusion is that the marsupial
strategy allows a much slower rate of
resource utilisation, first by the mother
and subsequently by the slower growing
offspring. "Viewed in this context, the

reproductive biology of marsupials
cannot be deemed less efficient than
that of placentals and may indeed have
considerable advantages in the range of
environments in which marsupials are
found."

This quotation may stand as the
theme of the volume itself, for it is a
conclusion that is reiterated by many
of the contributors whether in relation
to physiology, to biochemistry, to eco-
logy or to behaviour.

I have two criticisms for the editors
of *The Biology of Marsupials*. The first
is that almost half the chapters are
reports of hitherto unpublished work
more appropriate to a journal, or are
narrowly restricted to reviewing an
author's own work. A firmer editorial
direction to authors would have made
the book much more useful and better
value to the wider audience. Second,
those unfamiliar with marsupials are
likely to be confused by the variety of
synonyms and common names used in
different chapters. The worst example

occurs on p328 where four of the eight
species named in Table 19.1 are differ-
ent from the check-list; and the mar-
supial mouse *Antechinus swainsonii*
is provided with the generic name of
the common wombat. Uniform nomen-
clature throughout the volume could
easily have been achieved, since Kirsch
and Calaby in their chapter provide a
comprehensive check-list of all living
species of marsupials.

Despite these shortcomings, *The
Biology of Marsupials* provides many
reasoned and informed reviews, which
will be standard references for some
time to come, and which should help
to lay to rest the old and now unin-
formed view that marsupials are in-
trinsically inferior mammals unworthy
of serious study.

Non-linear acoustics

*Theoretical Foundations of Non-Linear
Acoustics.* By O. V. Rudenko and S. I.
Soluyan. Pp. 274 (Plenum: New York,
1977.) \$47.40.

NON-LINEAR ACOUSTICS deals with a
very wide range of fascinating phenom-
ena nowadays, including ultrasonic pro-
pagation, cavitation in liquids and large
amplitude stress waves in solids, as well
as the more familiar finite amplitude
waves in gases and liquids. Despite the
rapidly increasing practical applicability
of these phenomena, and despite the
review articles, it is a subject which
still receives far too little attention in
the West, where most of the activity is
motivated only by applications to
underwater sonar equipment, to pro-
pagation in aeroengine ducts or to
supersonic aerodynamics.

The Physics Department of Moscow
State University, under the late Pro-
fessor R. V. Khokhlov, has contributed
greatly to non-linear acoustics, and has
taken a wider view of the subject than
any other group. The book under
review is by two of Khokhlov's former
students, now distinguished in their
own right, and is devoted largely to
Soviet work. Some of the work is in
fact new, and much of it is made
accessible to Western readers for the
first time in this publication.

The book gives an account of theo-
retical developments in plane-wave pro-
pagation, with diffusion and relaxation,
of cylindrical and spherical waves, of
sound-sound interaction, acoustic

streaming, the propagation of non-
linear beams with lateral diffraction
included, and of phenomena occurring
in plane waves subject to stochastic in-
fluences of various kinds. Of these, the
last two are the most novel and repay
careful study. Throughout, the authors'
aim is to arrive quickly, though often
superficially, at a relatively simple gov-
erning equation-generalising the well-
known Burgers' equation for plane
flow, which is then solved by *ad hoc*
approximate techniques or numerical
methods. No attempt is made to use
modern asymptotic techniques (such as
have been used in Western work on
non-linear gas dynamic problems,
which are ignored in the references
given here). The book therefore loses
in the range of problems which can be
solved and to some extent in unity of
approach. Comparisons with experi-
ment are only made in a generalised
fashion.

Despite these criticisms this is a
valuable book, and should arouse much
interest in the West. The price, how-
ever, is high and the translation literal
and unidiomatic. More notes from the
translator would have helped; readers
will search in vain for a description of
the "Method of Stagewise Simplifica-
tions", and there is much more here in
similar vein. But Dr Beyer and the
publishers have served us nonetheless
by making this book available reason-
ably quickly after its appearance in
the USSR.

D. G. Crighton

*D. G. Crighton is Professor of Applied
Mathematics and Head of the Department
of Applied Mathematical Studies at the
University of Leeds, UK.*

IMPORTANT NEW IUPAC PUBLICATIONS

THE FIRST AND ONLY BOOK OF ITS KIND:

COMPENDIUM OF ANALYTICAL NOMENCLATURE - "THE ORANGE BOOK"

Definitive Rules 1977

Prepared for publication by:

H. M. N. H. IRVING, University of Leeds, UK, **H. FREISER**, University of Arizona, USA and **T. S. WEST**, Macaulay Institute for Soil Research, Aberdeen, UK

The only comprehensive source of all nomenclature recommendations relevant to analytical chemistry to be published, this Compendium is essential for all those engaged in scientific publications in the widest sense.

The Index has been prepared with the maximum amount of cross-referencing so that the reader seeking guidance on any particular point of nomenclature can be directed quickly to the relevant report or reports in which it has been discussed.

Contents (partial):

Preamble. Recommendations for the presentation of the results of chemical analysis. Recommendations for terminology to be used with precision balances. Recommended nomenclature for scales of working in analysis. Recommendations on nomenclature for contamination phenomena in precipitation from aqueous solution. Recommended nomenclature for automatic analysis. Recommendations for nomenclature of thermal analysis. Recommendations for nomenclature of mass spectrometry. Recommended nomenclature for titrimetric analysis. Report on the standardization of pH and related terminology. Practical measurement of pH in amphiprotic and mixed solvents. Recommended symbols for solution equilibria.

Of interest to: Analytical chemists in a wide range of disciplines.

METHANE

International Thermodynamic Tables of the Fluid State - 5

Prepared for publication by: **S. ANGUS**, **K. M. de REUCK** and **B. ARMSTRONG**, IUPAC Thermodynamic Projects Centre, Imperial College of Science and Technology, London

This book is the fifth in the series, which is intended to display in tabular form the best available values of the thermodynamic properties of fluids of scientific and technical importance.

The tables given are based on the work and advice of an international panel of experts in the field: of which much of the preliminary work was carried out in the U.S.S.R., and the later work in the U.S.A. The complete tables have been approved by a wide range of thermodynamicists, including the IUPAC Commission on Thermodynamics and Thermochemistry.

Contents: Preface. Introduction. Symbols. Units and Conversion factors. Experimental results. Two-phase regions. Single-phase region. Ideal gas properties. The equation of state. The IUPAC tables. Limits of the tables. Use and accuracy of tables. Recommendations for improvements of the tables.

Appendix: The density of liquid methane in the region of interest in custody transfer calculations.

Of interest to: Chemical, petrochemical, gas and heating industry - research, development and design departments.

Nature is pleased to announce a new book-ordering service to readers throughout the world.

To obtain one or more of the titles listed opposite (all recently reviewed in **Nature**) simply complete and return the order form (or a photocopy) or write giving **full** details. Orders must be accompanied by a cheque (personal or otherwise), postal order or money order for the total cost. **Postage (surface mail) and packing is free.**

Payment from overseas may be made in any currency at the prevailing exchange rate. Cheques should be made payable to **Nature.**

As all titles are ready for immediate despatch, we can guarantee a fast and efficient service.

All orders should be sent to:

**Nature Book Service
4 Little Essex Street
London WC2R 3LF**

Order Form

Author	Title	Publisher	Price	Reviewed in Nature	Quantity required
BARRETT, R. & JACKSON, D. F. (Not available to N. America, Australia, New Zealand and South Africa)	Nuclear Sizes and Structure	Oxford	£17.50	10 Nov.	
BILLINGHAM, N. C.	Molar Mass Measurements in Polymer Science	Kogan Page	£13.50	6 Oct.	
BLAKEMORE, C.	Mechanics of the Mind	Cambridge	£10.50 (Cased) £3.95 (Paperback)	10 Nov.	
BURCKHARDT, R. W., Jr	The Spirit of System: Lamarck and Evolutionary Biology	Harvard	£11.55	10 Nov.	
CALMANN, G.	Ehret, Flower Painter Extraordinary	Phaidon	£16.00	10 Nov.	
CAMILLERI, J. A.	Civilization in Crisis	Cambridge	£7.50 (Cased) £2.50 (Paperback)	10 Nov.	
CLARK, R. W.	Edison, The Man Who Made the Future	Macdonald & Jane's	£6.95	10 Nov.	
COOK, A. H.	Celestial Masers	Cambridge	£7.50	10 Nov.	
COOKE, R.	The Biology of Symbiotic Fungi	Wiley	£11.30	13 Oct.	
ESAU, K.	Anatomy of Seed Plants (2nd Ed.) (WIE)	Wiley	£6.75	22 Sept.	
FISHER, R. B.	Joseph Lister	Macdonald & Jane's	£7.95	10 Nov.	
FRIEDLANDER, S. K.	Smoke, Dust and Haze: Fundamentals of Aerosol Behaviour	Wiley	£11.35	6 Oct.	
FROESE FISCHER, C.	The Hartree-Fock Method for Atoms: A Numerical Approach	Wiley	£17.20	13 Oct.	
GRIBBIN, J.	White Holes, The Beginning and End of Space	Paladin	£1.50	10 Nov.	
HALLAM, A. (Ed)	Planet Earth	Phaidon	£7.95	10 Nov.	
HARRISON, G. A. (Ed)	Population Structure and Human Variation (International Biological Programme, Vol 11)	Cambridge	£17.50	29 Sept.	
HEDVIG, P.	Dielectric Spectroscopy of Polymers	Adam Hilger	£17.50	13 Oct.	
HODGKIN, A. L. and others	Pursuit of Nature	Cambridge	£7.50	10 Nov.	
HOYLE, F.	Energy or Extinction	Heinemann	£1.50	10 Nov.	
LEAKEY, R. E. & LEWIN, R.	Origins: What New Discoveries Reveal About the Emergence of Our Species and Its Possible Future	Macdonald & Jane's	£8.95	10 Nov.	
LEWIN, B.	Gene Expression, Vol 3	Wiley	£10.25	10 Nov.	
LOOR, F. & ROELANTS, G. E. (Eds)	B and T Cells in Immune Recognition	Wiley	£19.45	13 Oct.	
LOVINS, A.	Soft Energy Paths	Wiley	£9.00	10 Nov.	
NELKIN, D.	Science Textbook Controversies and the Politics of Equal Time	MIT Press	£9.10	10 Nov.	
PHILLIPS, D. L.	Wittgenstein and Scientific Knowledge	Macmillan	£10.00	10 Nov.	
PORTER, R.	The Making of Geology	Cambridge	£8.95	10 Nov.	
ROOSEN-RUNGE, E. C.	The Process of Spermatogenesis in Animals	Cambridge	£15.50	29 Sept.	
SPIEGEL-ROISING, I. & DE SOLLA PRICE, D.	Science, Technology and Society	Sage	£20.00	10 Nov.	
TUDGE, C.	The Famine Business (Not available to the USA and Canada)	Faber & Faber	£3.95	10 Nov.	
WELLS, A. F.	Three-Dimensional Nets and Polyhedra	Wiley	£22.00	29 Sept.	
WERNER, D. (Ed)	Biology of Diatoms (Not available to the USA, India and Australia)	Blackwell	£17.00	22 Sept.	
ZUCKERMANN, H.	Scientific Elite	Free Press/ Collier-Macmillan	£11.25	10 Nov.

NEW FROM MILES RESEARCH PRODUCTS

ENKEPHALINS

The newly identified
ligands for the opiate
receptor in brain*
have been synthesized
chemically and are
now available at 98%
or better purity.

	Code No.
Leu-Enkephalin (Try-Gly-Gly-Phe-Leu-HCl)	72-601
Met-Enkephalin (Try-Gly-Gly-Phe-Met)	72-602
Also available:	
Antisera to leu-enkephalin prediluted for RIA Procedures	61-390

*Hughes, J., Smith, T.W., Kosterlitz, H.W.,
Fothergill, L.A., Morgan, B.A., and Morris, H.R.,

¹⁴C-coenzyme A esters now available

[1-¹⁴C] Acetyl-coenzyme A
>50mCi/mmol CFA.452
2-5mCi/mmol CFA.390

3-Hydroxy-3-methyl
[3-¹⁴C] glutaryl-coenzyme A
15-30mCi/mmol CFA.577

[2-¹⁴C] Malonyl-coenzyme A
40-60mCi/mmol CFA.570

[1-¹⁴C] Palmitoyl-coenzyme A
50-60mCi/mmol CFA.583

[1-¹⁴C] Propionyl-coenzyme A
40-60mCi/mmol CFA.581

[1-¹⁴C] Stearoyl-coenzyme A
40-60mCi/mmol CFA.582

APPOINTMENTS VACANT

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London)

There is a vacancy for a Scientific Officer (Basic grade) in the Department of Medical Microbiology, King's College Hospital, Denmark Hill, London S.E.5. The Department is a combined Public Health Laboratory Service/University/Hospital laboratory. Suitable qualifications would be either a Ph.D. or the Special Examination of the I.M.L.S. Candidates should have 2-3 years post-qualification experience and preference will be given to those with training in electron microscopy. Duties will include running a diagnostic electron microscopy service and research and development in clinical virology. Whitley Council terms and conditions of service will apply. The Department may be visited by arrangement with Professor J. R. Pattison (01-274 6222 ext. 2480) from whom application forms may be obtained. Closing date for applications is February 23, 1978. 1333(A)

THE UNIVERSITY OF LANCASTER DEPARTMENT OF PHYSICS

A Postdoctoral Fellow is required to join a group working on the BIOPHYSICS of synthetic membranes under the direction of Professor R. H. Tredgold. The person appointed will make use of techniques currently under development to form bilipid layers on solid substrates. It is intended to form layers containing various active bio-molecules and to study their electrical and optical properties.

Applicants should be graduates in biochemistry, biophysics or biology and should possess, or be about to obtain a Ph.D. in a relevant field. The appointment is for two years.

Salary £3,761 to £3,975.

Further particulars may be obtained (quoting reference L23/D) from the Establishment Officer, University House, Lancaster LA1 4YW to whom applications (five copies) naming three referees should be sent not later than March 1, 1978. 1314(A)

Sharpe's

PLANT BREEDER

A qualified and experienced Plant Breeder is required to carry out a programme of plant breeding on a range of Agricultural Fodder crops. Applicants should possess an Honours Degree in Agricultural Botany or an equivalent related science and preference will be given to persons having practical experience in breeding Fodder and Grass crops.

Duties include the planning, execution and responsibility for the breeding programmes aimed at supplying the requirement of our Commercial Departments. The full assistance of our existing laboratory and field trials staff is available.

Remuneration will be based on age, experience and knowledge. There is a contributory pension scheme.

Apply with detailed curriculum vitae to:-

The Secretary,
CHARLES SHARPE & CO. LTD.
Sleaford, Lincs.

1364(A)

Agricultural & Public Health Entomologists

Plant Protection Division of ICI is seeking Entomologists to join its international technical development teams. They will be responsible for identifying short and long term product opportunities and bringing innovative thinking based on sound technical knowledge to the expansion of the Group's range of agricultural and public health insecticides. Duties will include providing technical advice to marketing colleagues, customers and research organisations and the organisation and control of field trials programmes.

The posts will be based either at the Divisions Headquarters at Fernhurst, near Haslemere, Surrey, or at its Research Station at Jealott's Hill near Bracknell, Berkshire. Extensive overseas travel will be an essential part of achieving the job objectives.

Successful candidates are likely to have degrees in Entomology with experience in agricultural or public health entomology. Preference will be given to candidates with overseas and/or industrial experience and with linguistic ability (preferably Spanish or Portuguese).

Salaries will be fully commensurate with the qualifications, experience and job responsibilities of the successful applicants, and fringe benefits will include membership of the ICI Profit Sharing Scheme and Pension Fund. Staff Restaurants and Recreation Clubs are run in each location.

For an application form please write or telephone: Mr. H.R.A. Brown, ICI Plant Protection Division, Jealott's Hill Research Station, Bracknell, Berkshire. Telephone: Bracknell 24701.

Plant Protection Division

1355(A)

Wellcome

Technical Officer

to manage an Electron Microscope Unit Bacteriology R & D Department

The Bacteriology Research & Development Department of The Wellcome Research Laboratories (Beckenham) wish to appoint, at a senior level, a Technical Officer who will be responsible for the daily routine operation of the Electron Microscope Unit, including equipment and staff.

The Electron Microscope Unit services the needs of a multi-disciplinary complex of research activities. Its facilities include both transmission and scanning microscopes as well as auxiliary equipment such as a shadowing and freeze etching plant.

Applicants should be fully conversant with various electron microscope techniques necessary for both transmission and scanning microscopes. The successful applicant will be expected to maintain equipment, accept considerable responsibility and is likely to have had at least five years full-time experience in electron microscopy. The salary will be commensurate with the duties

required, commencing in the range £4054—£5305, with prospects for progression.

The Wellcome Research Laboratories are situated in pleasant parkland surroundings within easy reach of Bromley and Beckenham and about 12 miles from Charing Cross. Conditions of employment are attractive and include four weeks' holiday, pension and sick pay schemes, a subsidised canteen and excellent sports and social facilities. Assistance with re-location will be granted where appropriate.

Please write giving brief details of qualifications and experience to R.V. Sutton Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS, quoting reference no. U/845.

(1371)A

Research in Therapeutic Applications of Immunology

The Pharmaceuticals Division of ICI is currently reorganising its research programme in applied immunological research. We wish to recruit a scientist with significant experience in immunology to join the present multi-disciplinary immunology group. It is anticipated that this post would be attractive to an immunologist whose research ideas require the support of chemistry, biochemistry and virology. The successful applicant, male or female, will be expected to assume a major innovative role in the discovery of therapeutic agents acting by modification of the immune system. Whilst the research programme will be directed towards a specific target the immunology group carries additional

responsibility for advice and training in relation to several other research programmes. Our modern research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes. Conditions of service, salary and assistance given to married staff in moving house are designed to attract and retain staff of high calibre.

Could you please write, giving details of qualifications and experience to:

Mr. M.F. Losse
Personnel Officer
ICI Pharmaceuticals Division
Mereside, Alderley Park
Nr. Macclesfield, Cheshire

**THE OPEN
UNIVERSITY**

Faculty of Science

Tenured Lectureships are available in the following discipline areas:

BIOLOGY (Head of Discipline: Professor Steven Rose): (a) *Neurobiology* (b) *Genetics*. Applications from candidates with experience in any aspect of these subjects will be welcome but preference will be given to those with special interest in:

(a) *CNS neurophysiology, developmental neurobiology or mammalian cerebral functions*. The person appointed will be involved in the production of a second level course in the biological bases of behaviour. (b) *Developmental or Evolutionary Genetics*. The person appointed will be involved in the maintenance of a second level genetics course and the production of a third level evolution course.

CHEMISTRY (Head of Discipline: Professor L. J. Haynes): Applicants should have special interests in any of the main branches (*physical, organic, inorganic*) of chemistry.

EARTH SCIENCES (Head of Discipline: Professor I. G. Gass): Preference will be given to applicants with interests and experience in *sedimentary (organic) geochemistry, isotope geology, structural geology, geomorphology and/or planetary geology*.

PHYSICS (Head of Discipline: Professor F. R. Stannard): Applications will be welcome from candidates with interests in any branch of physics.

The preparation of Open University courses involves writing course text and assessment materials, making television and radio programmes, devising home experiments, and planning and participating in Summer School activities. Applicants should have a keen interest in teaching and should be willing to work in course production teams. The successful candidates will be expected to maintain an active research programme. The appointments are available from as soon as possible.

Commencing salary will be within the lower part (£3,333-£4,190) of the Lecturer scale except in cases of secondment.

Further particulars and applications forms are obtainable, by postcard request please, from The Personnel Manager, (S2), The Open University, P.O. Box 75, Walton Hall, Milton Keynes, MK7 6AL. Telephone Milton Keynes 63868/9. (There is a 24-hour telephone answering service.) Please state clearly in which post you are interested.

Closing date for applications:
24th February, 1978. 1358(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF HUMAN GENETICS RESEARCH FELLOW

Postdoctoral biochemist required to work on a project concerned with investigating human fetal-specific and tissue-specific proteins. The appointment will be for one year in the first instance, on the scale £3,333 to £4,190 p.a., but it may be extended for a further 18 months.

Enquiries and applications, including C.V. and names of two referees, to Dr D. J. H. Brock, Department of Human Genetics, Western General Hospital, Edinburgh (telephone 031-332 2471) by March 10. Please quote Reference 5000. 1362(A)

PUBLIC HEALTH
LABORATORY SERVICE
BOARD
and
UNIVERSITY OF SURREY
Joint Appointment
CONSULTANT
MICROBIOLOGIST
AREA PUBLIC HEALTH
LABORATORY, GUILDFORD
READER/SENIOR
LECTURER
DEPARTMENT OF
MICROBIOLOGY,
UNIVERSITY OF SURREY

Applications are invited from registered medical practitioners, who should also possess a research qualification, for this newly created appointment, the duties of which will comprise 6 sessions per week in the Public Health Laboratory participating in hospital and public health microbiology for the relevant health districts, and 5 sessions per week in the University to include undergraduate and post-graduate teaching (with a substantial contribution to the M.Sc. Medical Microbiology degree course commencing in 1979) and research.

The employing authority will be the Public Health Laboratory Service Board and the salary on the N.H.S. Consultant scale. Other terms and conditions of service generally as for Consultants in the N.H.S. The University appointment will be as Reader or Senior Lecturer, depending on the qualifications and experience of the appointee. It is expected that the South West Thames Regional Health Authority will grant an honorary Consultant contract.

The Public Health Laboratory may be visited by arrangement with the Director, Dr R. Y. Cartwright (0483 66091), and the University by arrangement with the Head of the Department of Microbiology, Professor J. E. Smith (0483 71281, Ext. 687).

Full particulars may be obtained from the Secretary to the P.H.L.S. Board, 61, Colindale Avenue, London NW9 5EQ (01-200 2195), to whom applications (12 copies) should be sent to arrive not later than March 6, 1978, stating date of birth, qualifications, experience and published work, and naming three referees. 1361(A)

THAMES POLYTECHNIC
SCHOOL OF
BIOLOGICAL SCIENCES
TECHNICIANS

Applications are invited from suitably qualified and experienced persons for the following technician posts in the School of Biological Sciences:

1. Animal House Technician, Grade 4, to take responsibility for the day-to-day running of a small animal house. A recently qualified graduate in an appropriate subject and with some relevant work experience would be considered for the post.
2. Plant Physiology Technician, Grade 3, to take responsibility for the preparation of materials for plant physiology work and the care of the School's greenhouses. Applicants should have at least an O.N.D. or equivalent qualifications and three years experience.

For both posts some weekend work is involved.

Salary scales: Grade 3: £2,601 to £2,931; Grade 4: £2,835 to £3,216; including London weighting plus personal allowance (i.e. 5% of gross pay min. £2.50, max. £4.00).

Further particulars and form of application may be obtained from the Taffing Officer, Thames Polytechnic, Vellington Street, London SE18 6PF, to whom completed applications should be returned by February 21, 1978. 1349(A)

BIOCHEMIST

required by a Drug Research Company for clinical biochemical analysis and research in the development of biochemical analytical methods. Application form from the Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. 1325(A)

RESEARCH/Technical Assistant required for study of fetal and placental metabolism. Commencing salary according to qualifications up to £3,432 inc. L./W. Please write giving age and full details to Professor M. Young, Gynaecology Department, St Thomas's Hospital Medical School, London SE1 7EH. 1343(A)

CSIRO
AUSTRALIA

Commonwealth Scientific & Industrial Research Organization

Chief of Division

Division of Irrigation Research
Griffith, N.S.W.

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,300 of whom are research and professional scientists—located in Divisions and Sections throughout Australia.

General: Applications are invited for the position of Chief of the CSIRO Division of Irrigation Research which is vacant following the retirement of the former Chief, Mr. E. R. Hoare.

The Division is based at Griffith, in the Murrumbidgee Irrigation Area of New South Wales, and strategically located in relation to the main irrigation areas of South East Australia. These areas produce a wide variety of fruits and vegetables, rice and other grain crops and animal products.

The Division has well-appointed laboratories and facilities and provision for field work on two properties totalling 45 ha. It has a staff of 66 including 23 professional staff.

Duties: Chiefs of CSIRO Divisions are responsible to the Executive for the development, scientific direction, integration and management of research programs.

The Division's present research is mainly in the plant sciences, and covers crop breeding, environmental and biochemical physiology, crop adaptation and management, aquatic weed studies and engineering aspects of intensive crop production. To supplement this, the Executive will expect the Chief to develop a strong program on the management of soils and water.

In terms of industry orientation, the Division is concerned with temperate irrigated row crops. Although this is centred on Griffith, the Chief will be expected to develop a program of general relevance to the major temperate irrigation areas of Australia. The Executive would expect the Chief to develop strong links with external bodies

and with other CSIRO Divisions working in related areas.

The Executive believes that to develop these initiatives a vigorous and innovative approach will be required. Substantial research experience in plant science and/or soils and water is desirable.

Salary: Salary will be the subject of negotiation but will not be less than A\$72,495 p.a.

Tenure: The appointment carries Commonwealth Superannuation privileges subject to normal conditions. The position of Chief is offered for a negotiable term of the order of six years, with subsequent options for a further term, if mutually desired, or for a senior position in the Organization on an indefinite basis.

Further Information: Dr. A. E. Pierce, a member of the CSIRO Executive will be visiting the United Kingdom and the U.S.A. during the periods 3rd-12th April, 13th-21st April 1978 respectively, and will be available for discussions concerning the appointment with applicants and other interested parties. Those interested in discussing the appointment should contact The Minister (Scientific), Australian Scientific Liaison Office, Canberra House, 10-15 Maltravers Street, London, WC2R 3EH, England, or The Counsellor (Scientific), Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C. 20036, U.S.A. It may be possible to arrange such discussions at a number of points in the United Kingdom and the U.S.A. Scientists interested in discussing the appointment should ensure that the appropriate overseas office is contacted in ample time to enable suitable arrangements to be made.

Further information on the Division is available on request from the Secretary, CSIRO, P.O. Box 225, Dickson, A.C.T. 2602.

Applications: Applications for the position stating full personal and professional details, the names of at least two referees and quoting reference number 500/332 should reach:

The Secretary,
CSIRO,
P.O. Box 225,
Dickson, A.C.T. 2602,
AUSTRALIA
by 10th March 1978

IMPORTANT INTERNATIONAL PHARMACEUTICAL GROUP

located in **PARIS** is presently offering an **EXCELLENT CAREER OPPORTUNITY FOR A**

SENIOR PHARMACOLOGIST

to join his **DEPARTMENT OF BIOLOGICAL RESEARCH** as
TEAM LEADER

for :

- the **DISCOVERY** and **EVALUATION** OF NEW **ANTI-INFLAMMATORY DRUGS**
- the **INVESTIGATION** OF **FUNDAMENTAL ASPECTS** OF THE **INFLAMMATORY PROCESS**

Preference will be given to individuals with the following qualifications:

- Ph.D. degree and, if possible, M.D.
- Relevant postdoctoral and/or industrial experience (3-5 years).
- Good attitude towards team work.
- Age between 30 and 40 years.

An excellent salary and comprehensive benefit programme accompany this position.

Please send curriculum vitae to Box No. 1272(A), Nature Magazine, c/o Macmillan Journals Ltd., 4 Little Essex Street, London WC2R 3LF.

1272(A)

UNIVERSITY OF STRATHCLYDE COURSE SUPERVISOR – MANUFACTURING SCIENCES AND ENGINEERING

As part of the drive to attract high quality entrants to the engineering profession and to British manufacturing industry, and with the encouragement of the University Grants Committee, the University is introducing from October 1978 a special course designed to appeal to well qualified and highly motivated students and to prepare them for worthwhile careers in manufacturing industry.

Applications are invited from good honours graduates for the post of **COURSE SUPERVISOR** for the new course. In view of the nature and objectives of the course relevant industrial experience and close links with manufacturing industry are essential. It is envisaged that the Course Supervisor will be a qualified engineer but applications from persons otherwise qualified will be considered. Experience as a member of the academic staff of a University is also very desirable.

Salary on a scale rising to circa £8,000 per annum, or possibly at a higher level, with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 8/78) may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by February 21, 1978.

1315(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF MICROBIOLOGY

Applications are invited from Medical Graduates for the post of
LECTURER

in the Department of Microbiology. It is hoped that the successful applicant will be eligible for an Honorary Consultant Contract with the Leeds Area Health Authority (Teaching). Salary will be either on the clinical lecturer scale £3,742 to £7,440 (plus £312 supplement) (under review) or on the scale for lecturers with Honorary Consultant Contract £7,536 (plus £312 and £208 supplements) to £8,322 (plus £178 and £208 supplements) to £9,111 to £10,689 (plus £208 supplement). The department may be visited by arrangement with Professor E. Mary Cooke (Leeds 36171 ext. 41).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 96/8/D. Closing date for applications March 10, 1978.

1328(A)

SWISS FEDERAL INSTITUTE OF TECHNOLOGY (ZURICH) RESEARCH ASSOCIATE OR FELLOW IN BIOCHEMISTRY

Applications are invited for the post of Research Associate or Fellow to work on a project concerning protein sequence determinations. Experience in biochemistry, especially in the techniques of protein sequence determination is essential. A Ph.D. or equivalent is preferable. The project is supported for 2 years by a grant of the Swiss Federal Institute of Technology. The salary will be SFr. ~40,000.-/year (S ~20,000.-/year, £ ~15,000.-/year).

Applications, including the names of two referees, should be sent to Professor Dr K. H. Winterhalter, Labor für Biochemie I, Universitätsstr. 16, 8092 Zurich, from whom further details may also be obtained. Please quote Reference 1308 (A).

Biochemical Toxicologist

Occupational Medicine Laboratory £6,310-£8,000

The Occupational Medicine Laboratory at Cricklewood plays an important role in industrial safety by providing a biological monitoring service for industrial exposure to toxic materials, and by undertaking research and development into new monitoring methods. The laboratory has the benefit of an extensive range of equipment including computerised GC-MS.

This post requires a scientist with experience in the study of toxicological mechanisms to carry responsibility for day-to-day management of the laboratory and help the Deputy Director in the development of its research programme. In addition, the person appointed will undertake personal research into biotransformations of hazardous chemicals. The expansion of the laboratory's services will be closely linked to the progress made in this research.

Candidates must have had considerable experience of biochemical toxicology at responsible levels and should have a 1st or 2nd class honours degree in biochemistry or another relevant subject. Appointment will be as Principal Scientific Officer with starting salary within the range £6310-£8000. There are prospects to £11500 and a non-contributory pension scheme.

For further details and application form (to be returned by 3 March 1978) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). Please quote ref: S(A)677/2 (1329)A

 **Health and Safety Executive**

THE WELLCOME TRUST

Research Grants for Studies in the History of Medicine

The Wellcome Trustees invite applications for grants from post-doctoral scholars with historical training, who are currently associated with a university department in Britain and actively engaged in independent research.

Fellowships of up to two years will be considered to enable applicants to undertake a specific research programme related to some aspect of the history of medicine or medical science. By arrangement with the appropriate authorities, applicants with university posts could take a period of research leave and the cost of a temporary replacement be funded by the Wellcome Trust.

Applicants are asked to put forward their case in a letter of not more than two foolscap pages. A curriculum vitae and, in the case of unestablished workers, the name of a suitably qualified person who has agreed to supervise the research, must also be provided.

The closing date for applications is 31st March, and they should be sent to:-

The Grants Section (HOM),
The Wellcome Trust,
1, Park Square West,
London NW1 4LJ.

1389(A)

UNIVERSITY OF MANCHESTER

DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH ASSISTANT

in Electron Scattering

Applications are invited for the above post, which is for 14 months in the first instance, to work in a flourishing and productive group. The project involves the development of a new position-sensitive multidetector system for electrons which will be used in electron spectrometers and should have applications in a wide variety of fields. The salary is on the scale of £3,333 to £5,627 p.a. (under review).

Enquiries for further details and applications including curriculum vitae and the names of two referees to Dr John Comer, Physics Department, The University, Manchester M13 9PL.

1351(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF HUMAN ANATOMY

TWO TECHNICIAN

Grade III Appointments

Salary £2,455 to £2,788 p.a.

Two technicians are required to assist with biological research, a) in the field of embryology: work to include care of lower vertebrates and electron microscopy, b) in the field of neurobiology and nerve connections: work to include preparative techniques for electron microscopy and histochemistry, O.N.C. or equivalent and A levels in appropriate subjects desirable. The posts are for a period ending July 31, 1979. Applications should be made in writing to the Administrator, Department of Human Anatomy, South Parks Road, Oxford, with the names of two referees indicating for which post the application is being made.

1363(A)

MONASH UNIVERSITY

Melbourne, Australia

CHAIR OF PHYSIOLOGY

Applications are invited for a Professor of Physiology to replace Professor A. K. McIntyre, F.A.A., who will retire from the Foundation Chair at the end of 1978. It is expected therefore that the appointee will take up duty early in 1979. Applicants should be physiologists of distinction able to provide leadership and direction in the research and teaching activities of a large department with responsibilities in the Faculties of Medicine and Science. The present strengths in the research and teaching interests of the Department are in neurophysiology, muscle physiology including the physiology of smooth muscle and autonomic nervous system, endocrinology, renal physiology, circulatory physiology, biophysics and neuropharmacology. There are two establishment Chairs within the Department and a Personal Chair held by Professor M. E. Holman, F.A.A. The successful appointee will have the opportunity to act as Chairman in rotation with the present Chairman, Professor R. Porter, F.A.A., from whom detailed information about the department should be obtained.

Salary: \$A31,248 per annum. Superannuation is based on an endowment assurance scheme, the employee and employer contributing 5 per cent and 10 per cent respectively. A pre-clinical loading of \$A2,500 per annum will be paid to a medically qualified appointee.

Information on application procedure and further particulars may be obtained from the Academic Registrar, Monash University, Clayton, Victoria 3168, Australia, or the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

Applications should reach the Academic Registrar, not later than March 31, 1978. The Council reserves the right to make no appointment or to appoint by invitation at any stage.

1382(A)

UNIVERSITY OF SURINAME

FACULTY OF NATURAL RESOURCES

In the FACULTY OF NATURAL RESOURCES of the University of Suriname at Paramaribo, teaching and research positions are available in:

land and water management 1

(branches drainage/irrigation and land reclamation/conservation)

land and water management 2

(branches agrohydrology and soil physics)

Duties include:

- teaching in these subjects or branches thereof;
- in co-operation with colleagues and other experts to evaluate, adjust and develop further the programme of study;
- participation in the preparation and execution of the research programme of the faculty;
- carrying out of organisational activities in the fields of teaching and research.

Applicants should hold the degree of M.Sc. or equivalent with considerable research experience, preferably in the tropics. Possession of a Ph.D. is an advantage, as well as experience in university teaching.

Period of first contract 3 years, whereupon the contract may be extended. Annual salary is the equivalent of US \$10,000 (under review), the contract bonus approximately 25% thereof. On first appointment and on termination the University will pay the air passage and a baggage allowance.

Applications, including the personalia of the candidate and members of his family, a curriculum vitae, copies of relevant diplomas and testimonials, a recent photo, a list of scientific publications (if any), the names and addresses of three references, and a possible date for assumption of duties, should be addressed before 1 March 1978 to the Board of Governors of the University of Suriname, Kleine Waterstraat 8, Paramaribo, Suriname (South 1323(A)

nature

Nature is considering employing a physical scientist to assist Dr Stuart Sharrock, the Physical Sciences Editor. Such a person would have recently received a Ph.D. and would be hoping to develop a much broader appreciation of science. He or she would be expected to help Dr Sharrock in the assessment of manuscripts, work with other members of the *Nature* staff in compiling the various sections of the journal, establish contacts in the scientific community and, on occasions, write short pieces on recent scientific developments.

Write to Editor, *Nature*, 4 Little Essex Street, London WC2 enclosing a c.v. and any other material you consider relevant.

1375(A)

BIOCHIMICA ET BIOPHYSICA ACTA EDITORIAL SECRETARIAT

Applications are invited for a post in the B.B.A. Editorial Secretariat, which is located in Amsterdam. The Editorial Secretary will be one of a small team of biochemists involved in the selection of manuscripts for publication in the world's largest biochemical journal. The work involves the choosing of reviewers for submitted articles, and subsequent correspondence with authors and editors, leading to eventual acceptance or rejection of the manuscripts. The Secretariat also maintains close contact with the journal sub-editing team, and advises on matters such as nomenclature and terminology. They thus play a central role in the quality control of the journal.

Candidates should meet the following requirements:

- a wide knowledge of the biochemical sciences
- 2-4 years of postgraduate research experience
- initiative, decisiveness, tact and an eye for detail
- an excellent command of the English language
- age under 30 and resident in Europe

The job offers modern working conditions including excellent social services and a good salary and bonus system. Holidays amount to 22 working days per year, plus public holidays.

Applications, including curriculum vitae, should be addressed to:

The Personnel Department
Associated Scientific Publishers
P.O. Box 2400
AMSTERDAM
The Netherlands

Further details are available on request.

1373(A)

BACTERIOLOGIST HEAD OF LABORATORY

An opportunity exists to join a team of microbiologists engaged in chemotherapeutic evaluation of new drugs.

We seek an applicant with experience in bacteriology and perhaps chemotherapy. Preferred age 28-35 years. His (her) main responsibilities will be the development of new model infections, as well as the performance of efficacy and pharmacokinetic studies.

Our research is founded on an interdisciplinary approach, and successful applicants would have the opportunity to pursue basic research projects in well established research groups studying a wide range of biological problems.

We can offer excellent working conditions in well equipped laboratories. An attractive salary will be paid, and travel expenses from country of origin will be refunded.

Interested scientists are invited to send applications stating age, citizenship, qualifications and experience to Dr N. Zacherl, Personnel Manager, Sandoz Forschungsinstitut, A-1235 Wien, Brunner Strasse 59, Austria.

1346(A)

University College Hospital
Gower Street, W.C.1

Department of Obstetrics

Graduate Biochemist

Required for research work on the role of Hyperprolactinaemia in infertility.

The work involves setting up methods to measure Catecholamines by radio enzyme methods and Serotonin by Fluorimetry.

Appointment for one year in the first instance.

Starting salary £3,090 to £4,148 per annum depending on relevant postgraduate experience.

Application forms from Personnel Department
Tele: 01-387 9300 Ext 381 quoting ref: N/GW/AD

1360(A)

THE BRITISH COUNCIL

invites applications
for the following posts:

TEACHER OF
SILVICULTURE
TEACHER OF
BOTANY
(Iran)

Higher School of Natural Resources,
Gorgan

To teach up to B.Sc. level, give practical instruction, set and mark examinations, assist with curriculum development.

Qualifications: Degree plus post-graduate diploma, or preferably M.Sc., in forestry and/or related subjects and at least two years' relevant teaching experience. Men only, single or married candidates, maximum two children under five.

Salary: £5,048 to £6,180 per annum, tax-free.

Benefits: Personal and children's allowances, free furnished accommodation. Two year contracts.

Return fares are paid. Local contracts are guaranteed by the British Council. Please write briefly stating qualifications and length of appropriate experience and quoting reference number 77 HO 40-42 and title of post for further details and application form to The British Council (Appointments), 65 Davies Street, London, W1Y 2AA.

1386(A)

AGRICULTURAL RESEARCH COUNCIL POULTRY RESEARCH CENTRE

Applications are invited for a vacancy at the above Institute for a Higher Scientific Officer/Senior Scientific Officer. The person appointed will participate in an ongoing research programme in the Reproductive Physiology Section. Initially, the work will be concerned with the way in which lipoprotein is transported and partitioned between the various tissues of the body in laying fowls and other poultry and whether or not the mechanisms are associated with the differences in egg-laying characteristics.

Qualifications: 1st or upper 2nd class honours degree in biochemistry, physiology or an appropriate biological science and preferably a Ph.D. Experience in membrane and/or lipoprotein metabolism at the cellular level would be an advantage.

At least two years postgraduate experience is required for appointment at H.S.O. level and 4 years for the S.S.O. grade.

Salary: H.S.O. £3,745 to £4,976; S.S.O. £4,707 to £6,300, including current pay supplements. Non-contributory super-annuation scheme.

Application forms are available from the Secretary, Poultry Research Centre, West Mains Road, Edinburgh EH9 3JS. The closing date for applications is Tuesday, February 28.

1368(A)

Sharpes

LABORATORY TECHNICIAN—PLANT PATHOLOGY

We require a Laboratory Technician to take charge of a Pathology Laboratory under the direction of our Plant Breeders who are engaged in the development of a wide range of crops.

Applicants should have appropriate experience and possess a relevant technical qualification.

Duties include the maintenance of plant disease cultures, assisting with the testing of our breeding stocks for disease resistance, co-operating with our Satellite Seed Testing Station on assessment of disease infection in seed samples and some cytology. A fair amount of glasshouse and field work will be involved.

Remuneration will be based on age and experience. There is a contributory pension scheme.

Apply with detailed curriculum vitae to:—

The Secretary,
CHARLES SHARPE & CO. LTD.
Sleaford, Lincs.

1365(A)

The Daresbury Laboratory has a vacancy at Higher Scientific Officer level for research into the

THEORY OF ATOMIC AND MOLECULAR PROCESSES

The fields of interest of the Theory Group at Daresbury are atomic and molecular, solid state and nuclear.

At the Laboratory a major nuclear structure facility is under construction and work will soon begin on a purpose-built X-ray and ultraviolet source. An IBM 370/165 computer is installed at the Laboratory, and a computational science group has recently been established working mainly in the quantum chemistry area.

The appointment would be a permanent one at Higher Scientific Officer level made according to age, qualifications and experience in the range £3,245 to £4,454. There are also pay supplements of (a) £313.20 per annum and (b) 5% of total salary subject to a minimum of £130.50 per annum and a maximum of £208.80 per annum. There is a non-contributory superannuation scheme and a generous leave allowance.

Applicants, male or female, must possess a good degree in an appropriate subject plus two years relevant experience, and preferably a Ph.D. in the area of atomic and molecular theory or expect to obtain one in 1978.

Closing date: 21 February 1978.

Please write enclosing curriculum vitae, the addresses of two referees and quoting reference number DL/608/T to:

The Personnel Officer

DARESBUURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

975(A)

MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE

Carshalton, Surrey

Applications are invited for the post of Senior Research Officer in the Director's Department.

The successful candidate will be expected to assist the Director with:

- (i) personal assistance with his administrative duties
- (ii) a research programme designed to evaluate specific pathogen free cats.

It is hoped that he/she will be a mature person with an interest in scientific administration. Applicants should have a degree in biological science, together with a Ph.D., and previous experience with small animals would be an advantage although not essential. The post offers excellent conditions of service. Salary in the range £3,999 to £5,199 according to age, qualifications and experience, plus £354 London Weighting, plus £312 Pay Supplement, plus Variable Pay Supplement. Contributory Superannuation Scheme.

Applications, together with a curriculum vitae and the names of two referees should be sent to the Director, Medical Research Council Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

1377(A)

MRC

Medical Research Council

QUALIFIED TECHNICIAN (H.N.C. or equivalent)

required for research project in Clinical Science Laboratories, for up to three years from April 1, 1978, to study nutritional and biochemical aspects of vitamin K in man. Previous experience in the techniques of lipid biochemistry or organic chemistry desirable but not essential. Further details from Dr M. J. Shearer, Clinical Science Laboratories, Floor 18, Guy's Tower, Guy's Hospital, London Bridge SE1 9RT.

Salary for technician qualified as above up to £3,275 plus £354 London Weighting.

Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. H.M.

1359(A)

MONTANA STATE UNIVERSITY VISITING FACULTY POSITION(S)

One-year, part-time appointment beginning September 1978. Ph.D. or equivalent required. Particularly suitable for faculty on sabbatical leave. Some teaching required. Extensive research facilities. Outstanding outdoor recreational opportunities in scenic Rocky Mountain setting. Detailed curriculum vitae, list of publications and at least three letters of reference addressing both research and teaching abilities and accomplishments should reach Patrik Callis, Chemistry Department, Montana State University, Bozeman, Montana 59717, U.S.A. (406-994-4801) by March 15, 1978. An equal opportunity/affirmative action employer.

1367(A)

In the FACULTY OF NATURAL RESOURCES of the University of Suriname at Paramaribo, teaching and research positions are available in:

hydrology (water resources engineering)
and
rural home economics

Duties include:

- teaching in these subjects or branches thereof;
- in co-operation with colleagues and other experts to evaluate, adjust and develop further the programme of study;
- participation in the preparation and execution of the research programme of the faculty;
- carrying out of organisational activities in the fields of teaching and research.

Applicants should hold the degree of M.Sc. or equivalent with considerable research experience, preferably in the tropics. Possession of a Ph.D. is an advantage, as well as experience in university teaching.

Period of first contract 3 years, whereupon the contract may be extended. Annual salary is the equivalent of US \$10,000 (under review), the contract bonus approximately 25% thereof. On first appointment and on termination the University will pay the air passage and a baggage allowance.

Applications, including the personalia of the candidate and members of his family, a curriculum vitae, copies of relevant diplomas and testimonials, a recent photo, a list of scientific publications (if any), the names and addresses of three references, and a possible date for assumption of duties, should be addressed before 16 March 1978 to the Board of Governors of the University of Suriname, Kleine Waterstraat 8, Paramaribo, Suriname (South America).

1322(A)

UNIVERSITY OF LONDON CHAIR OF PHARMACOLOGY AT UNIVERSITY COLLEGE LONDON

The Senate invite applications for the above Chair and the Headship of the Department of Pharmacology at University College London. Initial salary to be agreed, but not less than £8,106 plus £450 London Allowance. Applications (10 copies) must be received not later than March 16, 1978 by the Academic Registrar. (N) University of London, Senate House, London WC1E 7HU, from whom further particulars should be first obtained.

1313(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF CHEMISTRY Applications are invited for the CHAIR OF INORGANIC CHEMISTRY

which will be filled from the beginning of the session 1978/79 or as soon as possible thereafter.

Salary will be within the professorial range.

Further particulars and forms of application, returnable not later than March 13, 1978, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD Ref. No. 554.

1347(A)

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY

Nairobi, Kenya

Applications are invited from suitably qualified candidates for the following vacancies.

RESEARCH SCIENTIST (SORGHUM SHOOTFLY PROGRAMME)

REF. SCI/77/12

Qualifications

Ph.D. with five or more years' post-doctoral experience in insect physiology, especially in endocrinology and eco-physiology. High quality research for Ph.D. and evidence for excellence since doctorate will be a distinct advantage.

Responsibilities

The successful candidate will carry out research in the field of sorghum shootfly and will collaborate with other research scientists in the programme which is mainly concerned with eco-physiological research in aestivation-diapause.

POSTDOCTORAL RESEARCH FELLOW (TERMITE PROGRAMME) REF. SCI/77/13

Qualifications

African Scientist, holding Ph.D. or M.Sc. degree in Zoology (Entomology, Physiology) with interest and practical experience in entomology, physiology and ecology. High quality research for Ph.D. or M.Sc. and evidence of creative imagination, careful observation and dedication to scientific work will be a distinct advantage.

Responsibilities

The successful candidate will be responsible for planning, conducting and evaluating experiments on behavioural physiology in tropical termites (communication, pheromones, orientation, construction etc) with special reference to the role of pheromones in the regulation of termite behaviour and caste differentiation.

Salary

Basic salary according to qualifications and experience but, in any case, will not be less than KShs. 86,400/- per annum for the Research Scientist and 66,000/- p.a. for the Post Doctoral Research Fellow.

Other benefits

These include gratuity, housing allowance, group medical insurance scheme, generous annual leave, travelling fare and transport reimbursement allowance.

Applications, giving detailed information on general education, professional qualifications, experience, marital status, age, present terms of employment (including salary), names and addresses of four referees (including one personal referee), and photostat copies of relevant certificates and diplomas should be addressed to:

The Administrative Manager, I.C.I.P.E., P.O. Box 30772, Nairobi, Kenya

to reach him not later than March 7, 1978. 1369(A)

MAX-PLANCK-INSTITUT FÜR BIOCHEMIE, MUNICH

Department of Connective Tissue Research

PROTEIN CHEMIST

required

Applications are invited for the post of Assistant Scientist to join a group working on the primary structure of connective tissue proteins, particularly those found in basement membranes.

Applicants should have a Ph.D. in chemistry or biochemistry. Postdoctoral research experience in protein chemistry and sequencing methods is an advantage.

Salary according to B.A.T. IIb scales. Initial appointment for 2 years with possibility of a permanent position.

Applications to Professor K. Kühn, Max-Planck-Institut für Biochemie, D-8033 Martinsried b. München, Germany. 1350(A)

NATIONAL UNIVERSITY OF LESOTHO

Applications are invited for the post of PROFESSOR AND HEAD OF THE DEPARTMENT OF CHEMISTRY. Consideration will be given to applicants with specialisation in any branch but the present staff will best be complemented by a physical-organic chemist. Candidates should preferably have an interest in undergraduate teaching as well as in research. The appointee will be expected to assume duties by August 1978. Appointment will be on renewable short-term contract. Salary scale: Professor R8,580 to R9,000 (£1 sterling equals R1.68). The British Government may supplement salary by £3,456 p.a. (sterling) for married appointee and £2,274 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Superannuation: Non-contributory for appointees on permanent terms of service. Appointees on short contract terms receive 25 per cent gratuity in lieu of superannuation for the first two years of the contract, rising to 27½ per cent and 30 per cent for each subsequent and similar period of service. 15 per cent inducement allowance for expatriates not qualifying for any supplementation scheme. Family passages, baggage allowance; reasonable rental for accommodation; education allowance for expatriates; vacation and study leave. Detailed applications (2 copies) to be sent with curriculum vitae together with names and addresses of 3 referees to Registrar (Appointments) National University of Lesotho, Roma Lesotho by March 1, 1978. Applicants resident in U.K. should send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 1357(A)

THE UNIVERSITY OF MANCHESTER LABORATORY TECHNICIAN (Research) Grade 5

Applicants must provide evidence of considerable competence in general and specialised histological techniques and ability to use all forms of modern apparatus is essential. They should have an H.N.C. or equivalent qualification and have had a minimum of 8 years relevant experience including experience in electron microscopy and auto radiographic procedures. The ability to instruct and supervise Junior Technicians is also a requirement. Candidates must be able to develop new techniques and be conversant with general research procedures.

Salary Scale £3,186 to £3,720 p.a. Applications in writing, giving details of age, education and qualifications, together with technical experience and the names of two referees should be made to Professor P. F. Harris, Director of the Anatomical Laboratories, Stopford Building, Oxford Road, Manchester M13 9PT. Closing date Friday, 24th February, 1978. 1383(A)

GUY'S HOSPITAL MEDICAL AND DENTAL SCHOOLS

RESEARCH ASSISTANT (Immunologist/Biochemist)

Pre- or postdoctoral immunologist or biochemist having experience in immunochemical techniques required for a period of two years in the first instance. The person is required to investigate immune responses to Streptococcus mutans in rhesus monkeys.

Salary according to qualifications and experience, with £450 per annum London Allowance and superannuation.

Apply in writing, with curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. I.M.4. 1348(A)

KENYATTA UNIVERSITY COLLEGE—KENYA

Applications are invited for the post of SENIOR LECTURER/LECTURER in the ZOOLOGY DEPARTMENT. Applicants should have Ph.D. in any field of Zoology. Preference will be given to those qualified to teach Invertebrate Zoology, fresh water Biology or fish Biology. Salary Scales—Senior Lecturer £K2,772 to £K3,600 p.a., Lecturer £K1,800 to £K3,096 (£K1 equals £1.35 sterling). The British Government may supplement salaries in range £3,354 to £4,128 p.a. (sterling) for married appointee or £2,184 to £2,880 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowance and holiday visit passages. Terms of service include family passages, superannuation, subsidised housing, medical aid scheme plus various allowances. Detailed applications (2 copies) with a curriculum vitae and naming 3 referees to be sent to Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya by February 28, 1978. Applicants resident in the U.K. should send one copy to Inter University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 1356(A)

UNIVERSITY OF ASTON IN BIRMINGHAM DEPARTMENT OF PHARMACY Cancer Chemotherapy Group CONTRACT

RESEARCH FELLOW

Our multidisciplinary group has a vacancy for a POSTDOCTORAL RESEARCH FELLOW, who has a background in biochemistry or biochemical pharmacology, to join the investigation of the effects of certain antitumour agents on folate metabolism. The work is supported by the Cancer Research Campaign with a commencing salary within the range £3,333 p.a. to £3,975 p.a. (under review).

Preliminary enquiries may be made to Dr J. A. Hickman, Department of Pharmacy (Tel: 021-359 3611 Ext. 6066). Application forms and further particulars may be obtained from the Staff Officer, University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (Tel: Ext. 201) to whom applications should be returned (quoting Ref. No. 249/6) not later than March 3, 1978. 1341(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF CHEMISTRY POSTDOCTORAL

RESEARCH ASSISTANT

required from September 1, 1978 for work in collaboration with Dr T. M. Cresp on the total synthesis of biologically active sesquiterpenes. Salary: £3,569 plus £450 London Allowance: U.S.S. The post is tenable for one year with possible renewal for a second year. Applications, consisting of curriculum vitae and names of two referees, should be sent as soon as possible to Dr T. M. Cresp, Dept. of Chemistry, University College London, 20 Gordon St., London WC1H 0AJ, U.K. 1379(A)

RESEARCH TECHNICIAN (Grade 5)

required in Technical Services Section. Applicants should have some experience of electron-microscopy and be familiar with routine histological techniques. 37½-hour week, Monday to Friday. Pension scheme, excellent working conditions and 4 weeks annual holiday. Salary range £3,651 to £4,185 per annum including London weighting. Applications, stating details of experience and qualifications, should be sent to Mr C. L. Meredith, Departmental Superintendent, Zoology Department, Imperial College, London SW7. 1378(A)

EAST MALLING RESEARCH STATION MAIDSTONE, KENT

Director

Applications are invited for the post of Director of the East Malling Research Station which will become vacant when the present Director retires early in 1979.

The Station, financed by a grant-in-aid from the Agricultural Research Council, is concerned with basic and applied research on the propagation, culture and cropping of fruit and other perennial woody plants, their protection against pests and diseases and post harvest treatment including storage.

Candidates should be eminent in one of the scientific disciplines relevant to the work of the Station, with proven ability in the conduct and management of research and an awareness of the problems of practical horticulture.

The appointment is in the grade of Chief Scientific Officer; salary £11,878 including Phase 2 pay supplement. There is a non-contributory superannuation scheme.

Applications are to be submitted by 28th April, 1978 to the Secretary, East Malling Research Station, East Malling, Maidstone, Kent ME19 6BJ from whom further details are available. 1338(A)

ELSEVIER/NORTH HOLLAND BIOMEDICAL PRESS

have a challenging position available for a

SCIENTIFIC JOURNALIST

to edit a topical magazine in the Biochemical Sciences.

We are looking for a good writer, capable of taking decisions under pressure and working to deadlines. He/she will be expected to liaise with external editors in processing reviews and gathering/rewriting news and views.

An advanced qualification and/or research or teaching experience in the biosciences is preferred, with proven writing ability and possibly with some experience of publishing and editing.

The position will be based in Cambridge but mobility will be a definite advantage as the successful candidate will be expected to spend some time in Amsterdam and to travel to scientific meetings.

Further information on this post may be obtained from Dr. J. Franklin in Amsterdam, telephone 020-5153152. Applications with career details and salary required should be addressed to The Personnel Dept., ASP, P.O. Box 2400, Amsterdam, The Netherlands. 1374(A)

JUNIOR TECHNICIAN

required in Department of Chemical Pathology to assist with routine assay of steroid hormones by radioimmunoassay and with research project on steroid receptors in human endometria. Salary according to age, and qualifications within scale £1,733 to £2,758 p.a. plus £354 p.a. London Allowance. Apply with full details and names of two referees to: The Secretary, St Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. JT/CP/N. 1336(A)

UNIVERSITY OF IDAHO

Assistant or Associate Professor/Ornamental Horticulturist. University of Idaho. Responsibilities: approximately 80% teaching, 20% research. Ph.D. required. Position available after July 1, 1978. Position open until acceptable candidate is selected. Inquiries should be sent to: Ornamental Horticulture Position, Dept. of Plant & Soil Sciences, University of Idaho, Moscow, Idaho 83843. (Ph. 208/885-6276. A.A./E.O. employer and educational institution. 1148(A)

UNIVERSITY OF SURINAME FACULTY OF NATURAL RESOURCES

In the Department of Geodesy of the Faculty of Natural Resources of the University of Suriname at Paramaribo, teaching and research positions are available in:

A Photogrammetry and

B Calculus of observations

Duties include:

- teaching in these subjects and in land surveying;
- in co-operation with colleagues and other experts to evaluate, adjust and develop the programme of study;
- participation in the preparation and execution of the research programme of the faculty;
- carrying out of organisational activities in the fields of teaching and research.

Applicants should hold the degree of M.Sc. or equivalent with considerable research experience, preferably in the tropics. Possession of a Ph.D. is an advantage, just as experience in university teaching.

Period of first contract 3 years, whereupon the contract may be extended. Annual salary is the equivalent of US \$10,000 (under review), the contract bonus appr. 25% thereof. On first appointment and on termination the University will pay the air passage and a baggage allowance.

Applications, including the personalia of the candidate and members of his family, a curriculum vitae, copies of relevant diplomas and testimonials, a recent photo, a list of scientific publications (if any), the names and addresses of three references, and a possible date for assumption of duties, should be addressed before 16 March 1978 to the Board of Governors of the University of Suriname, Kleine Waterstraat 8, Paramaribo, Suriname (S. Am.). 1321(A)

ROTHAMSTED EXPERIMENTAL STATION Harpenden, Herts. AL5 2JQ ASSISTANT STATISTICIAN

to analyse data from agricultural and other biological experiments using the Station's computer and to help in the supervision of the data-processing staff. Degree, H.N.C. or equivalent qualification in mathematics or statistics. Some knowledge of agriculture or biology an advantage.

Appointment in grade of Scientific Officer £2,592 to £4,032 including pay supplements. Starting salary according to qualifications and experience. Non-contributory superannuation.

Applications, giving names and addresses of two referees and quoting ref. 350 to the Secretary by March 3, 1978. Further details on request. 1353(A)

TROPICAL POST-HARVEST PHYSIOLOGIST

The United Fruit Co. needs a plant physiologist with specialisation in post-harvest physiology in its research laboratories in Central America.

Prior experience in the tropics and a knowledge of Spanish would be useful but are not essential requirements.

Salary starts at U.S. \$16,000 per annum with low local income tax; pension scheme, health insurance and good local junior schooling coupled with educational assistance for older children; annual home leave of 28 days with family transportation paid; costs of removal of successful applicant will be met by the Company.

Please apply with curriculum vitae and addresses of two referees to: Manager Administration, Tropical Research Division, United Fruit Co., La Lima, Rep. of Honduras, Central America. 1366(A)

Experimental Officer -Drug Metabolism

The Pharmaceuticals Division of ICI has a vacancy for an Experimentalist to work in the Drug Metabolism group of its Safety of Medicines Department. The job holder, male or female, will be responsible for metabolism studies on candidate drugs, but will report to a PhD qualified scientist. Applicants should have experience of liquid scintillation counting and combustion techniques for the assay of labelled drugs in body fluids and in vivo techniques of studying the metabolism of drugs. The successful candidate is also likely to possess a first degree or equivalent in Chemistry.

Our modern research laboratories are situated in pleasant surroundings, but within easy reach of main road and rail routes. Conditions of service, salary and assistance to married staff in moving house are designed to attract and retain staff of high calibre.

Please write giving details of qualifications and experience to, Mr. M. F. Losse, Personnel Officer
ICI Pharmaceuticals
Division
Mereside Research
Laboratories
Alderley Park
Nr. Macclesfield
Cheshire
1344(A)

Higher Scientific Officer £3,254 - £4,454

(plus supplements)

Applications are invited for a pensionable post in the Department of Commerce, Industrial Science Division, which is presently located at 16 Comber Road, Newtownards but will shortly be transferred to Lisburn.

The post is in the Metallurgy and Metallurgical Chemistry section and the duties include providing a rapid technical investigation service to industry in this field from production problems and material selection to component failures. Practical experience of metal failures, welding defects, corrosion, heat treatment, electroplating and chemical analysis of metals using modern instrumental techniques is essential. Experience in Photomicroscopy and Macro photography would be an advantage.

Applicants must be under 30 years of age on 31 December 1978 with a 1st or 2nd class honours degree in Chemistry, Metallurgy or a related subject and at least 2 years' appropriate post graduate experience.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

There are excellent promotion prospects to Senior Scientific Officer (£4,185-£5,778) and Principal Scientific Officer (£5,514-£7,205). Starting salary will be related to qualifications and experience.

In addition to the salary scales quoted pay supplements of between £310.59 and £522.00 per annum will be payable.

Please write or telephone for an application form, quoting job reference SB 61/78/NA, to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 23rd February 1978. 1326(A)

**NORTHERN IRELAND
CIVIL SERVICE**

THE UNIVERSITY OF MANCHESTER DEPARTMENTS OF SURGERY AND PATHOLOGY

Postdoctoral IMMUNOLOGIST required with experience in the techniques of Cellular Immunology as applied to patients. The post is for one year initially, but renewable. The objective is to study the nature of the immune deficit in injured and malnourished patients. A full-time technician in Immunology and adequate laboratory facilities will be available for the project. Salary scale for Research Staff with starting point up to £4,811 p.a. Enquiries to Professor W. L. Ford, Department of Pathology, Stopford Building, Oxford Road, Manchester M13 9PT or to Professor M. Irving, Department of Surgery, Hope Hospital, Eccles Old Road, Salford M6 8HD. Applications to Professor Irving by February 20. 1327(A)

THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON LECTURER IN PHARMACEUTICAL CHEMISTRY

Applications are invited from suitably qualified persons who have an interest in, and an ability to teach Organic/Inorganic Chemistry. Applicants should have some teaching and research experience, and should normally possess a higher degree.

Normal non-clinical university academic terms of appointment. Point of entry to Lecturer Salary Scale dependent on qualifications and experience.

Applications, by not later than February 28, 1978, in the form of a letter accompanied by curriculum vitae to:-

The Personnel Officer,
The School of Pharmacy,
29/39 Brunswick Square,
London WC1N 1AX,

from whom further information may be obtained. 1312(A)

UNIVERSITY OF BIRMINGHAM DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post of:

LECTURER IN BIOCHEMISTRY

tenable from October 1978, or earlier.

The successful candidate will be expected to participate in the general and specialised teaching programmes of the Department which provides courses for science, medical and dental undergraduates. Excellent facilities are available for most types of biochemical research.

Salary within the range £3,333 to £4,403 p.a. (plus U.S.S.), depending on age, qualifications and experience.

Applications (3 copies) naming 3 referees should be sent by March 6, 1978 to the Assistant Registrar (Senate), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. 1311(A)

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF AGRICULTURE AND HORTICULTURE

Applications are invited for a
**LECTURESHP IN
HORTICULTURE**

which will be effective from the beginning of the session 1978/79. Preference will be given to candidates who have specialised in aspects of fruit or vegetable production.

Salary will be within the range £3,333 to £6,655 but the appointment will be made initially within the first three points of the scale (£3,333 to £3,761) per annum.

Further particulars and forms of application, returnable not later than February 28, 1978, from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref. No. 555. 1318(A)

MARINE SCIENCES RESEARCH LABORATORY MEMORIAL UNIVERSITY OF NEWFOUNDLAND RESEARCH SCIENTIST AQUACULTURE

To conduct research on problems directly related to aquaculture in Newfoundland. The scientists will be expected to assume increasing responsibility for conducting projects already in progress and advise on major changes where appropriate.

A Ph.D. in experimental animal biology. Research experience on live animals is essential. Applicants must be prepared to conduct research in the field as well as in the laboratory. Ability to liaise with non-scientists is important.

A research scientist at the M.S.R.L. enjoys essentially the same privileges as an academic appointment.

The M.S.R.L. is located three miles from St John's and is a modern well-equipped research laboratory.

Salary is commensurate with qualifications and experience.

Please respond with a biographical sketch, list of publications and three references by March 31 to:

Dr D. R. Idler, Director
Marine Sciences
Research Laboratory,
Memorial University
of Newfoundland,
St John's, Nfld.,
Canada A1C 5S7 1385(A)

STATISTICIAN

The Forestry Commission offers a period appointment of 3 years for a Statistician at their Forest Research Station, Alice Holt Lodge, Wrecclesham, Farnham, Surrey.

The successful candidate will work with a small team of Statisticians advising on the design and analysis of R&D projects in Forest Management and Protection; develop mathematical models for problems in protection of forests and trees against pests, work study etc; co-operate with forest scientists to improve the use of statistical methods and write computer programs to implement mathematical models.

Candidates (who should normally be aged under 30 at 31 December 1978) should have a good honours degree in mathematics with statistics or MIS with experience. **Salary:** within the range for Scientific Officer (£2149—£3527) or for Higher Scientific Officer (£3254—£4454) depending on qualifications and experience. Supplements of £313.20 and 5% of total earnings subject to a minimum of £130.50 per annum and a maximum of £208.80 per annum are also payable on each pay scale.

Closing date for applications: application forms and further details may be obtained from Mr C Robbins, Personnel Branch, Forestry Commission, 231 Corstorphine Road, Edinburgh EH12 7AT. Completed application forms should be returned not later than 20 March 1978.

(1380)A

NATIONAL INSTITUTE OF AGRICULTURAL BOTANY CHEMIST/BIOCHEMIST

(Ref. SV/182N)

TECHNICAL OFFICER (Trainee) required in the Institute's Chemistry and Quality Assessment Branch for analytical work on oilseeds. Candidates, preferably under 28 years of age, must have a first or second class honours degree, or equivalent in an appropriate discipline; experience of gas chromatography would be an advantage.

Salary £2,892 to £3,588 including supplements.

Further particulars and application forms from the Establishments Officer, National Institute of Agricultural Botany, Huntingdon Road, Cambridge CB3 0LE. Telephone: Cambridge 76381, ext. 234.

Closing date February 28, 1978.
1387(A)

UNIVERSITY OF ALBERTA

The Department of Geology, University of Alberta, Edmonton, Alberta, Canada T6G 2E3 invites applications for a full-time continuing faculty position in the field of clay mineralogy from July 1, 1978 or as soon as possible thereafter. The preferred applicant should have a mineralogical background and be prepared to apply his researches to local sedimentological problems, and/or the industrial uses of clays. The appointment will be at the Assistant Professor level (current salary level \$17,625 to \$22,888 plus health, pension and insurance fringe benefits).

Applications, with names of three referees, should be sent to the Chairman of the Department, from whom further details may be obtained. Closing date May 31, 1978.

1309(A)

RESEARCH ASSISTANT

required in Department of Experimental Pathology to investigate human papovavirus infection in pregnancy. Post tenable for one year in first instance. Candidates should have a good B.Sc. or M.Sc. in Biology or related science. Experience in Virology, electron microscopy or cytopathology an advantage. Project suitable for thesis or higher qualification. **Salary** £3,377 p.a. including London Allowance. Apply, The Secretary, St Mary's Hospital Medical School, Paddington, London W2 1PG quoting Ref. RA/EPC/N. 1335(A)

FREIE UNIVERSITÄT BERLIN

Klinikum Steglitz FB 2 WE 05

IMMUNOLOGY

RESEARCH UNIT

POSTDOCTORAL RESEARCH ASSISTANT AH 1

Applications are invited for the above position which will begin on April 1, 1978. The applicant with several years experience in Immunology will join the group of Professor Diamantstein working on the mechanism of lymphocyte activation and on regulation of the immune response.

Salary approximately £8,000 to £8,500 p.a. (minus tax) depending on experience, age, family status. Applications to: Professor Diamantstein, Klinikum Steglitz, Freie Universität Berlin, Hindenburgdamm 27, 1000 Berlin 45, Germany. 1324(A)

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, PATERSON LABORATORIES

A limited number of appointments will be available from October 1, 1978 for full-time studies leading to higher degrees at the University of Manchester. The selected areas of cancer research are concerned with biochemistry, cell biology, cytology, haematology and immunology.

Applicants should have a good Honours degree in science or hope to obtain a First or Upper Second Class degree in 1978.

Remuneration will be at the rates applicable to postgraduate students supported by the Medical Research Council (M.R.C.).

Applications should be sent to Professor L. G. Lajtha, Paterson Laboratories, Christie Hospital & Holt Radium Institute, Withington, Manchester M20 9BX. Ref. 78/6. 1316(E)

MISCELLANEOUS

BRITISH FOUNDATION FOR AGE RESEARCH invites

Research Projects in Incontinence of the Elderly, for which funds are available. Closing date Friday, March 10, 1978

Details and Application Forms from the Director BFAR, 101, Queen Victoria Street, EC4P 4EP. 1372(J)

Director

of the Poultry Research Centre, Edinburgh

Applications are invited for the post of Director of the Agricultural Research Council's Poultry Research Centre which will become vacant when the present Director retires on the 27th June, 1978.

The work of the Centre is concerned with research on domestic poultry and their environmental needs which include work in the fields of physiology, anatomy, nutrition and behaviour much of which involves interdisciplinary collaborative research.

Candidates should have qualifications or equivalent experience in one or more of these subjects together with a proven ability in the conduct and management of research. Preference will be given to candidates with relevant experience of poultry research.

The post of Director is graded Deputy Chief Scientific Officer, the initial point on the salary scale being £10,180 rising by two annual increments to £11,190. In addition a Phase II supplement of £208.80 per annum is currently payable. There is a non-contributory pension scheme.

The closing date for applications is 27th February 1978. Further particulars and application forms may be obtained from Dr. Gareth M. Price, Agricultural Research Council, 160, Great Portland Street, London, W1N 6DT. 1337) A

Theme: Cell Biology and Biochemistry of Leukocyte Function. Topics include, leukocyte membranes; cytoskeleton; lymphocyte activation; thymic factors; lymphokines; cytotoxicity; leukocyte killing; genetics; intercellular co-operation; viruses, radiation and carcinogenic agents; application to clinical medicine. Registration forms and information will be sent on request. Professor M. R. Quastel c/o Secretariat, P.O.B. 16271, Tel Aviv, Israel. 1320(C)

COURSES

UNIVERSITY OF LONDON KING'S COLLEGE NEW INTERCOLLEGIATE COURSE

starting October 1978

M.Sc. IN HUMAN AND APPLIED PHYSIOLOGY

A one-year course to train graduates in measuring and studying the physiological functioning of man in normal and abnormal environments. The course would equip students to specialise in the applications of physiology to man in industrial, service and clinical situations and the teaching of human physiology. Topics include: basic measurements; life support systems; exercise; locomotor; postural; climatic; high altitude and hyperbaric physiology. Applicants should normally have a good degree in Physiology or be medically qualified.

Further details and application form from Dr S. Rowlands, King's College, Strand, London WC2R 2LS, quoting reference 191602/N.

Closing date for applications: March 31, 1978. 1388(D)

THE UNIVERSITY OF MANCHESTER

M.Sc. IN OCCUPATIONAL HYGIENE

(by part-time study)

Held on two days a week, this two-year course comprises four terms of formal teaching sessions, covering the social, scientific and engineering aspects of occupational hygiene and nine months of research study aimed at providing first hand experience in the evaluation of the working environment. The course is open to science or engineering graduates currently employed as occupational hygienists. Further details from Dr F. F. Cinkotai, Department of Occupational Health, Stopford Building, The University, Manchester M13 9PT. 1340(D)

FELLOWSHIPS

UNIVERSITY COLLEGE
LONDONDEPARTMENT OF CHEMISTRY
POSTDOCTORAL FELLOW

Applications are invited for a post-doctoral fellowship for work on the application of microwave spectroscopy to the study of simple hydrogen bonded complexes, in collaboration with Professor D. J. Millen and Dr A. C. Legon. Applications, including curriculum vitae and names of two referees, should be sent to Professor D. J. Millen, Department of Chemistry, University College, 20 Gordon Street, London WC1H 0AJ. 1354(E)

UNIVERSITY OF
BIRMINGHAMDEPARTMENT OF PHYSICS
RESEARCH FELLOWSHIP

Development of well-logging instrumentation

Applications are invited from Physicists or Electrical Engineers with research experience to design and develop a prototype Nuclear Magnetic logging device for measuring the porosity and permeability of rocks penetrated by water wells. The project will involve close collaboration with the Hydrogeological and Geophysics sections of the Department of Geological Sciences and with the Hydrogeology Division of the Institute of Geological Sciences. Salary (under review) in the range £3,333 to £5,627, plus superannuation; maximum starting salary will be £3,975, tenable from April 1, 1978 for one year with probable extension of one year.

Applications (3 copies) including full curriculum vitae and the names of three referees should be sent to the Assistant Registrar, Science and Engineering, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, by Friday, February 17, 1978.

Please quote ref: ND4. 1332(R)

UNIVERSITY OF SYDNEY
POSTDOCTORAL

RESEARCH FELLOWSHIPS

Applications are invited for the above-mentioned awards from candidates who hold a Ph.D. degree or have research publications revealing equivalent status.

The Fellowships are not intended for persons who are in, or have occupied a career position since being awarded the Ph.D.

The Fellowships, which are tenable in any field, are valued at between \$A12,872 and \$A14,286 p.a. and provide return fares. They are tenable for one year with the possibility of renewal for a second year.

Further information is available from the Registrar, University of Sydney, NSW 2006, Australia, with whom applications close on 1 May 1978. 1381(E)

OF HEALTHVISITING FELLOWSHIP IN
BIOPHYSICAL CHEMISTRY

Applications are invited for a post-doctoral fellowship of one to two years duration for development of novel methods of measuring the oxygenation of haemoglobin and the aggregation of sickle haemoglobin.

Applicants should be non-U.S. citizens with less than two years post-doctoral experience. Starting salary \$10,000 to \$10,800 plus benefits.

Applications (with curriculum vitae) or letters of inquiry should be addressed to Dr A. P. Minton, Laboratory of Biophysical Chemistry, N.I.A.M.D.D.-N.I.H., Bethesda, Md. 20014, U.S.A. 1310(E)

UNIVERSITY OF SURREY

DEPARTMENT OF
METALLURGY & MATERIALS
TECHNOLOGY

Applications are invited for the post of Redland Research Fellow tenable in the Department of Metallurgy and Materials Technology at the University of Surrey.

The research programme carried out by the Fellow will relate closely to the research and development interests of Redland Limited, and the Fellow normally carries out a number of subsidiary investigations requested by the Company's Research and Development Centre. The post affords an excellent opportunity for the incumbent to familiarise himself with industrial research and to make the transition from academic to the industrial environment.

Applicants should have a Ph.D. or equivalent experience in some area of material science, or solid state chemistry. Preference may be given to candidates with interests or experience in silicate chemistry, Portland cement and ceramics. In view of the nature of the appointment, candidates having the ability to formulate new experimental approaches to unresolved problems would be preferred. The Fellow appointed will undertake research in materials of interest in construction and building and the main concern will be with property structure relationships of interest in developing new or improved materials.

The appointment would be made for two years in the first instance, renewable thereafter on a yearly basis.

Remuneration will depend on age and experience and will be in the range £3,333 to £3,761 (under review), on scales related to the University lecturers' scales. Applications, from men and women, in the form of a curriculum vitae, with the names and addresses of three referees, should be sent to:

Professor J. E. Bailey,
Department of Metallurgy and
Materials Technology,
University of Surrey,
Guildford, Surrey GU2 5XH. 1317(E)

SYMPOSIUM

LEUKAEMIA RESEARCH FUND

International Research Symposium on

"BONE MARROW TRANSPLANTATION"

will be held at the Royal College of Physicians, London, on Monday, May 10, 1978. Registration fee (includes lunch) £6. Apply for details and registration form to:

Leukaemia Research Fund,
43 Great Ormond Street,
London WC1N 3JJ.

Tel: 01-405 0101 1342(M)

AWARDS

SASKATCHEWAN SCHOLARS PROGRAM

The Saskatchewan Research Scholar Awards are to encourage and assist researchers who have demonstrated high promise in research and scholarship. Scholars receive \$17,000.00 per year for two years, possible renewal for a third year. Ph.D. (or equivalent) and normally one or two years additional experience, plus the ability to do independent research. Scholarship may be held in any field, Humanities, Social Sciences, Life Sciences, Physical Sciences or Engineerings. Canadian citizens and landed immigrants have priority. Closing date for application May 15, 1978 for awards to commence between July 1, 1978 and January 1, 1979.

Further information and application forms available from The Dean, College of Graduate Studies and Research, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0. 1331(N)

STUDENTSHIPS

SIR WILLIAM DUNN
SCHOOL OF PATHOLOGY

University of Oxford

RESEARCH STUDENTSHIP

Applications are invited from students expecting to graduate in 1978 with a good honours degree in biochemistry or chemistry and wishing to undertake research (leading to the degree of D.Phil.) on the biochemistry of penicillinases.

The studentship's value is at the level of a state grant and includes the payment of approved fees.

Applications, including a curriculum vitae and the name and addresses of two referees, to Dr S. G. Waley, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. 1352(F)

SCHOLARSHIPS

IMPERIAL COLLEGE OF
SCIENCE & TECHNOLOGY
ROYAL DUTCH SHELL
SCHOLARSHIP IN GEOLOGY
OR GEOPHYSICS 1978-1979

Normally of equivalent value to an N.E.R.C. Postgraduate Studentship plus supplementation, plus college fees and approved fieldwork expenses. Tenable for up to three years of research in a topic which falls within Shell's general field of interest. Candidates must have taken, or be taking in the year of award, either an honours degree in Geology preferably with mathematics and/or Physics at ancillary level, or an honours degree in Physics. Candidates should be not more than 27 years of age, and medically fit to work abroad.

Applications, on a special form obtainable from the Registrar, Imperial College, London SW7 2AZ, must be received by April 14, 1978. 694(H)

THE NATIONAL KIDNEY
RESEARCH FUND

invites applications for grants for renal research at units within the United Kingdom. Application forms are available from The Secretary, 184B Station Road, Harrow, Middlesex HA1 2RH (01-863 4469). 1258(H)

FOR SALE & WANTED

CASH AVAILABLE

For purchase of small quantities of rare or new (not catalogue) organic compounds. Price guide; around £10 per 2g. specimen.

Nedor Consultants Ltd.,
Stowford House, Stowford,
Lewdown, Devon. 1339(L)

Kirk International Publishers
invite book manuscripts in
Earth Sciences and Natural
Sciences.

Kirk International
Publishers,
Bredgade 14-16,
DK-1015 København K
Denmark. 1370(L)

UNIVERSITY OF OXFORD
INORGANIC CHEMISTRY
LABORATORY

S.R.C. C.A.S.E. AWARDS

Applications are invited from graduates (or students expecting to graduate shortly) with a good Honours Degree or an M.Sc. in Chemistry, Physics or Materials Sciences for Studentships to work on the project of which details are given below. Each Studentship will be tenable for three years, and that part of the work to be carried out in the Inorganic Chemistry Laboratory will be supervised by Dr L. A. K. Staveley.

1. Experiments designed to assist the prediction of the thermodynamic properties of liquid mixtures involving (a) the study of the equation of state of pure and liquefied gas mixtures such as methane-tetrafluoromethane to 1300 bar (b) the measurement of the excess thermodynamic functions of binary liquefied gas mixtures such as xenon-hydrogen sulphide. The processing and application of the results will be carried out in collaboration with Dr R. M. Gibbons of the Research and Development Division of the British Gas Corporation. The project therefore offers the student an excellent training in cryogenic, vacuum, high-pressure and computing techniques.

2. Calorimetric studies of zinc sulphide and zinc selenide. This will involve making heat capacity measurements on these substances from 520K down to 10K, and if necessary to 1K. The measurements which must be of the highest precision will be made on specially prepared samples which have been pretreated (e.g. annealed, irradiated) in various ways. The thermodynamic work will be supplemented by neutron diffraction studies to be carried out at A.W.R.E., Aldermaston, under the supervision of Dr K. Lewis. The aim of the co-operation is to investigate the relationship between the heat capacity of the two substances and their defect structure. The project will therefore give the student experience of precision-low-temperature calorimetry and neutron diffraction and reactor techniques.

Applications giving a brief curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to Dr L. A. K. Staveley, Inorganic Chemistry Laboratory, South Parks Road, Oxford. 1330(N)

LECTINS

New Tools for Cancer, Cell Surface,
Glycoprotein and Polysaccharide Research

28800	CONCANAVALIN A, JACK BEAN: (<i>Canavalia Ensiformis</i>)

7-Ethoxycoumarin: substrate for a rapid, sensitive, fluorometric assay of microsomal monooxygenase activity

The mixed-function oxidase system in liver microsomes plays an important part in the metabolism of drugs. For this reason, sensitive and reliable tests are necessary for determining enzyme activity and consequently the drug-metabolizing capacity of the system.

7-Ethoxycoumarin has been found¹ to be an excellent substrate for the direct fluorometric determination of microsomal monooxygenase activity. The assay is based on the O-dealkylation of **7-ethoxycoumarin** to produce the highly fluorescent 7-hydroxycoumarin (umbelliferone, catalog number H2400-3).

This system involves cytochrome P-450 containing monooxygenases and is dependent on NADPH and molecular oxygen.

Since it is well known that microsomal monooxygenases are induced typically by phenobarbital and polycyclic aromatic hydrocarbons, *e.g.*, 3-methylcholanthrene (MC), the effect of these on O-deethylation of **7-ethoxycoumarin** was studied. Phenobarbital and MC induced O-deethylation of **7-ethoxycoumarin** in hepatic tissues² and in isolated rat liver cells,³ whereas only phenobarbital induced the O-deethylation in extrahepatic tissues.⁴

It has also been demonstrated that MC inducibility of 7-ethoxycoumarin O-deethylase and aryl hydrocarbon hydroxylase is determined genetically in the *Ah* locus.⁵ Poland *et al.*⁶ have shown that O-deethylase is also inducible by 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD).

An improved fluorometric assay for microsomal

monooxygenase determination via **7-ethoxycoumarin** O-deethylation has been developed recently.⁷ This *in vitro* fluorometric assay is at least *ten* times as sensitive as present methods, and has facilitated the kinetic studies of O-deethylase activity as well as a reevaluation of the use of **7-ethoxycoumarin** O-deethylation as an indicator of phenobarbital-induced monooxygenase activity in mice.⁷

This assay enables nearly quantitative recovery of the major product, 7-hydroxycoumarin, by extraction and the product is essentially free of fluorescent contaminants. Maximal fluorescence of 7-hydroxycoumarin in aqueous solution is obtained at pH 9.5 or higher. O-Deethylase activity induced by phenobarbital, MC and TCDD was studied by this method.⁷

The advantages of using **7-ethoxycoumarin** as a substrate are that the compound is not known to be carcinogenic, it is not particularly light-sensitive, and it is dealkylated to a single, highly fluorescent product.⁷ **7-Ethoxycoumarin** has been rigorously purified to eliminate as much background fluorescence as possible.

7-Ethoxycoumarin should prove to be a useful indicator of a wide range of monooxygenase inducers, particularly in cancer research.

Immunological Products

A package of new products from Flow Laboratories

Lymphocyte Separation Medium . . . 20 ml, 100 ml, 500 ml packs are available. No minimum order; excellent quality control ensures: density of $1.077 \pm 0.001 \text{ g ml}^{-1}$; a high yield purity and viability of lymphocytes and susceptibility to PHA stimulation.

Lymphocyte Storage Medium . . . for storage of lymphocytes at room temperature. This modified McCoy's 5A is supplemented with antibiotics, foetal bovine serum and HEPES buffer

RPMI 1640 powdered medium with HEPES buffer . . . RPMI and four other powdered media are now available containing 20mM HEPES buffer.

Human AB Serum . . . for human lymphocyte stimulation experiments. Human AB is claimed to be less blastogenic than heterologous serum

See what LKB Ultrogel[®] will do for your separations!

LKB Ultrogel[®] is a new kind of gel filtration medium, which now turns gel filtration into a high-resolution technique. High resolution because of the inherent characteristics of Ultrogel: small, rigid, uniform beads with a narrow size-distribution.

When different Ultrogel types are used for serum fractionation, they can do this for you:

Bed dimen.: 1.2 × 55.6 cm
Flow rate: 5.0 cm/h
UV-detection: Curve 1, 280 nm T × 1 Curve 2, 254 nm T × 1

Bed dimen.: 1.2 × 46.8 cm
Flow rate: 5.0 cm/h
UV-detection: Curve 1, 280 nm T × 5 Curve 2, 254 nm T × 5

Bed dimen.: 1.2 × 48.8 cm
Flow rate: 2.6 cm/h
UV-detection: Curve 1, 280 nm T × 5 Curve 2, 254 nm T × 5

Buffer: 0.05M phosphate, pH 7.0, containing 0.171M NaCl and 0.02% NaN₃

Sample: 0.3 ml human serum (70 mg protein/ml)

Uvicord III

monitoring: For AcA 44, 100—0% transmission (T);
for AcA 34 and AcA 22, 100—80% T with automatic switching to 100—0% T

HUMAN SERUM PROTEINS SEPARATED ON LKB ULTROGEL.

IgG and albumin are indicated for the Ultrogel types AcA 44, AcA 34 and AcA 22. It is seen that AcA 44 is the best gel for separating IgG and albumin; with AcA 34 and AcA 22 the separation is reduced.

The void peak (arrowed) in AcA 44, containing proteins much bigger than IgG, is resolved into two peaks on AcA 34, and further resolved into three peaks on AcA 22.

Thus, for separating high-molecular weight proteins, AcA 22 is recommended, whereas AcA 44 is more suitable for fractionation of proteins with molecular weights around 100,000.

Ultrogel type	Effective fractionation range*
AcA 22	100,000 — 1,200,000
AcA 34	20,000 — 350,000
AcA 44	10,000 — 130,000
AcA 54	5 000 — 70 000

* Globular proteins

Ultrogel is a pre-swollen polyacrylamide/agarose gel which can be used straight from the bottle. No time-consuming swelling procedures are needed.

If you really want high resolution in gel filtration, write to the address below for more information, or order Ultrogel directly from the types listed in the table.

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; $\exp(a)$ is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors. (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Cellulose ion exchangers should be spherical too

DEAE-Sephacel[®] is

DEAE-Sephacel[®]
Total capacity: 1.4 meq/g
Wet diameter: 40–160 μ m

The spherical form of DEAE-Sephacel gives you easy, uniform packing without the generation of fines. It improves your results because it reduces zone broadening and ensures uniform, high flow rates. DEAE-Sephacel is reproducible from batch-to-batch.

No precycling is needed because DEAE-Sephacel is ready swollen. Its controlled macroporous structure, which is almost completely independent of pH and ionic strength, gives high protein capacities and excellent recoveries.

DEAE-Sephacel is the only spherical cellulose ion exchanger.

Vietnam's dioxin problem

Much of Vietnam was sprayed with herbicides during the war. **Alastair Hay** reports on local research to assess the damage caused.

MANY times has the United States been accused of using Vietnam as a testing ground for some of the more sophisticated techniques of modern warfare. Indeed, that accusation featured prominently in much of the Vietnamese propaganda material produced during the last ten years of the war. The Vietnamese, however, were not the only accusers: United States scientists were among some of the more vocal critics of their country's military policies. Many of them made it known that they deplored such practices as the use of chemical defoliants; the implementation of weather-modification techniques; the development of plastic-pellet bombs, the intention of which was to produce shrapnel undetectable by x-rays; and the training of dolphins and porpoises to place limpet mines. All these they considered to be perversions of scientific endeavour.

Their opposition, however, had little effect upon the United States' military

activity. In many instances, information was made public only long after the event and the United States always denied emphatically that Vietnam was used as a test site for the development of military technology. But it was the first country in which defoliants were used on a large scale purely to achieve a military objective.

Originally research into 2,4-dichlorophenoxyacetic acid (2,4-D) and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T) and related herbicides had been carried out during the Second World War. The British later tested their effectiveness in small-scale operations during the Malayan 'emergency' of the 1950s. But it was the success of herbicide evaluation trials in South Vietnam, Thailand, Hawaii and Puerto Rico which led to the chemicals being employed on a vast scale in Vietnam. According to a US National Academy of Sciences report of 1974 on 'Herbicides in South Vietnam', more than 10% of the inland forests, 36% of the

mangrove forests, 3% of cultivated and 5% of 'other' land was sprayed "one or more" times.

NAS estimates of the total volume of herbicide dropped on Vietnam are 17.5 million gallons, of which 11.25 million gallons was in the form of 'Agent Orange' (a 50:50 mixture of the n-butyl esters of 2,4-D and 2,4,5-T). Criticism of the use of these herbicides on ecological grounds had little impact on the actual spraying missions. With powerful advocates in the American Chemical Society defending the use of herbicides as a more 'humane' form of warfare, it required more than a concern for ecology to bring the spraying to an end.

When the US Department of Health, Education and Welfare published a report in 1969 announcing that 2,4,5-T was teratogenic in rats and mice, the herbicide programme diminished. The report was confirmed by a later independent study which established that commercial preparations of 2,4,5-T contained a highly toxic contaminant, 2,3,7,8-tetrachlorodibenzo-p-dioxin (dioxin), a teratogen at the μg per kg level in experimental animals.

Sample stocks of Agent Orange retrieved from Vietnam for analysis by the manufacturer, the Dow Chemical Co., revealed dioxin to be present in concentrations of 0.05–47 ppm. On the basis of these figures, it has been estimated that at least 100 kg of dioxin was deposited on Vietnam.

Not just a matter for science

The damage caused by herbicides is a subject of some concern to the Vietnamese authorities, and is an area of investigation for some of the country's scientists and clinicians. If the dioxin problem in Vietnam was simply one of scientific investigation, more published information would be available by now for scrutiny. But some authorities in Vietnam fear that information on the herbicide damage will be used by the military in the United States to refine its chemical warfare techniques.

Dr Tran Tri, one who voices that anxiety, is in charge of scientific relations with western countries. He says that the dioxin issue is a "complicated" matter and adds: "Of course, there is a scientific aspect to this problem which the Americans have used; our scientists, however, will not use the results in the same way". Tri wants Vietnamese scientists to do much of the general investigation on dioxin. Because of the sensitivity of the subject, he states categorically that only very few of those foreign scientists who have expressed an interest will be able to participate.

Not all Vietnam's scientists agree with Tri's interpretation. Some feel sure that the United States has more

VIETNAM occupies a long narrow strip of Indo-China. The South China Sea is the eastern boundary and a series of mountain ranges in the west act as a natural frontier with Laos and Kampuchia.

Most of Vietnam's population estimated at 50 million reside in the coastal plain and the delta regions of the Red River and the Mekong. Hanoi, the capital city, houses about 1.3 million people; Ho Chi Minh City has about 3.5 million. Five sixths of the country's population is, ethnically speaking, true Vietnamese; some 39 minority groups, of which the "Montagnards" and Chinese settlers are the largest, account for the other sixth.

Vietnam has had various occupation forces in the past two millennia. China kept her as a province from 111 BC until ousted by a national Vietnamese army in 905 AD. Subsequent attempts by successive Chinese emperors to recolonise Vietnam met with no success and the country enjoyed independence until occupied by French troops in 1858. French suzerainty in Vietnam ended in 1954, only to be partially replaced by an American presence in the south of the country. The United States, however, had a much shorter stay than France. American involvement in Vietnam finally ended with the fall of Saigon (now Ho Chi Minh City) to Communist troops in April 1975.

The war in Vietnam has exacted a heavy toll on the country with most of her resources being devoted to the war effort. The result of this is that the per capita income is exceedingly low and United Nations sources confirm that Vietnam

qualifies for urgent development aid. The distribution of aid provided by foreign donors is therefore the subject of some scrutiny. Vietnam does, however, ration food to ensure fair distribution. She has a free education programme and places great emphasis on preventive medicine. These are strategies which are generally welcomed by the international development agencies.

Vietnamese poultry killed by toxic chemicals

than enough information on herbicides. Scientists in the West working on 2,4,5-T and dioxin are of the same opinion. They point to the herbicide trials undertaken in South-East Asia in the 1960s, and to those run by the US Air Force in Florida from 1962 to 1974. Reports of the Florida experiments—which also contained information on the toxicity and biological degradation rates of dioxin—were declassified in October, 1976, to enable the Italian authorities to make use of them in dioxin decontamination work following the accident at Séveso.

Two of those most involved with the herbicide issue in Vietnam are a cytologist Dr Bach Quốc Tuyen; and Professor Ton That Tung, a surgeon and director of the Viet Duc hospital. Tuyen is in charge of the cytogenetics laboratory at the Bach Mai Hospital in Hanoi. His department was virtually destroyed when the hospital was the target of the 'Christmas bombing' of the city in December 1972.

Reporting chromosomal abnormalities

The cytogenetics department is compiling a register of the incidence of malformation in several districts both in and around Hanoi. It will be the first register to provide an accurate picture in this part of Vietnam, says Tuyen. As a scientist, he is better known for his work on chromosome mapping, and as one of the authors of two papers, published in Vietnam, which claim that the incidence of chromosome damage in people exposed to the herbicide 2,4,5-T (and its dioxin contaminant) in the American defoliation programme is higher than expected. But the number of people involved is too small to indicate statistically significant trends. This is "because we did the work

during the war", says Tuyen, and he adds: "We had no opportunity to do a controlled epidemiological survey".

Some scientists in the West have levelled another criticism at Tuyen's reports. They say that the Vietnamese have reported as abnormal a level of chromosomal abnormalities—gaps and breaks—considered normal in the West. Tuyen estimates that in Vietnam these abnormalities are of the order of 0.4%; for the West and Japan, they are much higher—at 1.0% or more. To what does Tuyen attribute this higher rate? "Chemicals. Perhaps a higher background level of radiation". And is he satisfied that his laboratory techniques are above reproach? "Yes. Scientists from Holland have verified the accuracy of our work".

Lack of contact with the West

Like many of the Vietnamese scientists, Tuyen is unable to obtain much of the published literature from the West, due mainly to the effects of war, and current lack of resources. Tuyen would welcome more contact with western scientists. He feels that it is important to conduct further studies to confirm two earlier reports by American scientists on the effects of herbicides on Vietnam.

One of the reports, in the US Congressional Record for 2-9 March 1972, states that there was a marked increase in the incidence of stillbirths in one province, Tay Ninh. The second report—by Arthur Westing to the Swedish Academy of Scientists meeting in February 1977—speaks of an increase in the rate of spina bifida and cleft palate in a Saigon (Ho Chi Minh City) children's hospital from 1966-68, the years of the heaviest spraying programmes. Tuyen is convinced that the

defoliation programme has resulted in an increase in the rate of birth abnormalities and chromosomal aberrations, but, until further information is available, he acknowledges that this conclusion is still very uncertain.

The same is true of Professor Tung's suggestion that dioxin may be responsible for an increase in primary carcinoma of the liver in Vietnam. Although Tung's publications and public statements on the subject are more categorical, he says privately that dioxin cannot be identified as the sole agent; the evidence for the link with cancer is circumstantial and there is no good epidemiological evidence to support it. He feels that there are many other possible factors to be considered, with aflatoxins and viruses obvious suspects. With a department specialising in the removal of liver tumours, however, Tung has seen an increasing number of patients referred to him for surgery, who do not come from any one particular area of the country. This makes it difficult to pinpoint any one agent.

In the opinion of many western scientists, the evidence implicating dioxin is very slim. They point out that there is a remarkably short time between the deposition of dioxin—beginning in 1962—and the appearance of liver tumours. Most known carcinogens have a latency period of between 20 and 30 years.

The final group of scientists involved in the assessment of herbicide damage are the zoologists at the Vietnam Scientific Research Centre in Hanoi. Dr Ngoc Quang, one member of this group, has some preliminary evidence of changes in the pattern of bird life in sprayed areas. "Normally", he says, "there is a population of about 40 peacocks per hectare. In areas sprayed with herbicides, there are none". He also reports a reduction in the pheasant population, and adds that scientists in Vietnam are "anxious to have help to assess the damage to our fauna. The changes we have recorded may not be due to the herbicides; there may be other causes."

Resolving the 'dioxin problem' is not one of Vietnam's top priorities; there are too many other areas, medical and agricultural, requiring urgent, immediate attention. What the long-term effects will be it is impossible to say; the evidence is just not available. With contamination on this scale, Vietnam is in a unique situation, not to be envied. It is to be hoped that, when she asks for assistance from the scientific world, it will be promptly forthcoming. □

Alastair Hay was recently in Vietnam as a Nature travelling fellow. He was supported in part by the London Technical Group.

The great American dream machine runs out of fuel

David Dickson discusses the dilemmas facing the Carter administration over the future shape of the US space effort

FIRST the good news. President Carter's administration has proposed that the space science budget of the National Aeronautics and Space Administration (NASA) be increased by 26.7% to a record level of \$513 million—out of a total NASA budget of \$3,305 million—in 1979.

Now the bad. There are no plans to start any new planetary missions in 1979, and it now appears that apart from Project Galileo, the Jupiter Orbiter/Probe given the go-ahead by Congress last year, no major new planetary programme is likely to be under way until the mid-1980s.

It is almost exactly 20 years since the US entered the space race with the launch of the Explorer satellite from Cape Canaveral on 30 January, 1958 as a hastily arranged response to the trauma of being beaten into space by the Russian Sputnik. It is also the 20th anniversary of the National Aeronautics and Space Act of 1958, which established NASA. And last week, in celebration of the latter event, the Senate Committee on Commerce, Science and Transportation held a symposium on the future of space science and space technology.

If the future facing space science 20 years ago lay full of hope and promise, the symposium indicated how confused and uncertain the picture is today. This confusion is reflected in doubts about the future directions that NASA should pursue, indeed doubts about the whole shape of the US space effort, including space science.

Two areas are doing well. The first is space astronomy, with exciting results on X-ray and gamma-ray emission already coming from the High Energy Astronomical Observatory (HEAO), launched last year, and more promised from the Large Space Telescope, which is being started in the 1978 budget. The second area which is also expanding, and which reflects the administration's desire to see an emphasis placed on the basic research necessary to support applied research, lies in the area of space applications. Here the relative complexity of some new applications of satellite technology, such as earth resources reconnaissance and climatology, at least in comparison to earlier applications such as telecommunications, have given rise to a significant increase in the supporting science.

But there are two areas in which current frustrations are running high, and short-term expectations—in spite of vigorous pressure—remain low. The first is in what has been called "space industrialisation", where the imagination of space engineers, with plans for mining asteroids for important minerals and creating vast solar receptors to beam energy down to earth, have so far not been matched by any major commitment from NASA. The agency claims that it is holding back work on large space structures until it sees the outcome of the Space Shuttle programme.

Planetary science

Planetary science is the second area in which NASA appears to be holding back from any major future commitment. Admittedly the present situation for planetary science is not too bad, largely because of the success of scientists in getting the Jupiter Orbiter/Probe into the 1978 budget. (Indeed, the main reason for the substantial 26.7% increase in the 1979 space science budget is last year's acceptance by Congress of this and the space telescope, both projects requiring substantially more funding in the second rather than the first year).

But the Jupiter project only survived in NASA's programme after a considerable battle in Congress, which required mustering the full letter-writing potential of the planetary science community. Although accepted by the Senate, the project was rejected in a surprise move by the House Appropriations Committee under the chairmanship of Mr Edward Boland (Dem-Mass), and only scraped through following compromises made at the conference stage.

Less fortunate has been a proposed project to send a spacecraft into a polar orbit around the Moon, making use of a set of matched sensors that would have provided a survey of the whole planet from a height of 100 km. This had been proposed within NASA in three successive years, and twice (for 1978 and 1979) put forward by NASA to the Office of Management and Budget, only to be rejected on each occasion. It now seems unlikely that NASA will be prepared to put forward this project again, preferring to rethink how it should reapproach the

Moon at a later date, possibly in five or ten years' time.

Two other projects discussed within NASA failed to get the agency's support. The first was the proposal to send a spacecraft to rendezvous with Halley's Comet, due to make its once-in-75-years approach to the sun in 1986. A second project was a proposed follow-up to the Viking mission to Mars, either sending a roving vehicle to the planet to gather more information about its surface, or to arrange for a sample of Mars rock to be brought back to earth for analysis.

The possibility of a Mars project is still receiving enthusiastic backing from scientists, particularly those interested in investigating the distribution of organic matter in the universe. And there will be a considerable push this year to get a trip to Mars in 1986—the next date when the planet will be in a suitable position relative to the Earth—into the 1980 budget.

However, it will have to compete with another equally attractive proposal, that to send an imaging radar device to orbit Venus in order to make the first accurate measurements of the planet's surface through its dense clouds. A Venus project could be particularly attractive for two reasons. Firstly, there are already two planned Pioneer trips to Venus planned for launching in May and August of this year, and interest in the planet is therefore likely to be high. Secondly, and perhaps politically more important, is the fact that the Russians are planning both a fly-by mission, probably with an orbiter, and also a joint mission with the French that will involve dropping a balloon into the planet's atmosphere.

Apart from these there are a number of additional projects being proposed, each with its group of supporters. One is to send a mission to Titan, the largest of Saturn's moons, whose atmospheric conditions make it of particular interest to space scientists with biological interests. Those disappointed by the failure to gain support for a mission to Halley's Comet still contend that a comet mission of some kind would provide invaluable information about the origins of the universe. And there is also a project being discussed to reintroduce manned investigation in the relatively near future with a mission to one of the many small bodies, such as the nuclei of burnt-out comets, that orbit the Sun close to the Earth.

Each of these projects would be fruitful from both a scientific and a technological point of view. The main problem facing planetary scientists, however, is how to secure that extra bit of commitment from the administration necessary to obtain the vast amount of resources that each would require.

Artists' impression of NASA's space telescope

Victims of earlier success

The size of the projects, the uncertainties involved, and the long-term nature of any pay-off, make it impossible to apply with any degree of accuracy the type of cost-benefit analysis that is increasingly being required of R & D efforts. As Dr Noel Hinners, associate administrator for space science at NASA, points out, "scientists have desires, not requirements."

But in their failure so far to gain the necessary backing, the hawks of both space technology and space science are partially the victims of their own earlier success. On the one hand, the apparent ease with which the space bonanzas of the 1960s were achieved, and the technological euphoria which they generated, has obscured the type of commitment needed to secure success; recent launcher failures and technical problems with Space Shuttle engines have made both administrators and politicians more cautious in their projections of feasibility.

The second spin-off from earlier successes has been that, by putting the emphasis on the more competitive aspects of getting places first, it has been made comparably harder to argue for follow-up missions of equal, if not greater, scientific value. Both the proposed lunar and Mars projects which failed to receive funding for 1979 suffered partially from this problem.

The resulting situation was expressed at the Senate symposium by Professor James Arnold, of the Department of Chemistry at California University, La Jolla, and a leading advocate of the lunar mission. "The lunar and planetary science community currently feels a great frustration based on the paradox that we have very exciting things that we know how to do, but

budgetary restrictions on doing them," he said.

This frustration, shared with those who would like to see NASA advancing rapidly into large technological structures, finds a frequent echo in Congress from those who argue the need for the US to maintain a position of superiority both in leading the pursuit of new knowledge, and in maintaining a technological advantage over other nations (NASA's formal role is according to the National Space Act to preserve the role of the US "as a leader in aeronautical and space science and technology").

But this style of political debate, however attractive it may have appeared during the Cold War period when politicians could play on the fear of Soviet technological superiority, is out of place in the current administration. The form of hegemony that President Carter sells is moral, rather than technological (just as the success of *Star Wars* is based less, as the space hawks like to suggest, on the inherent attractions of space travel as on the apparent victory of morality over technology).

Thus, however much he is attacked for showing a lack of imagination, space bonanzas, whether scientific or technological, are not Carter's style; like other candidates for federal aid, they require pragmatic justification, in the way that NASA is putting increasing emphasis on the "useful applications" of space technology—and the science necessary to achieve it—rather than the more glamorous aspects.

Dr Robert A. Frosch, NASA's newly appointed director, is under pressure from both Congress and the aerospace industry to take a more "imaginative" approach. But he is proceeding cau-

tiously, and as a result finds himself "in the somewhat paradoxical situation that as steward of NASA I have been cast in the role of the conservative, a brand new position for both me and the agency."

Looking to the future

As the NASA budget for 1979 comes under scrutiny from Congress, there are likely to be several attempts to increase both its size and its scope. Already Representative Olin Teague, for example, has been persuaded to table a resolution pressing the investigation of space resources. And representative Ronnie G. Flippo of Alabama echoed a widely-held feeling when he told the House two weeks ago that the 1979 budget was in general "a *status quo* budget, lacking in the kind of action, boldness and innovation which should characterise scientific leadership."

But in general space is much lower on Congress' priority list than it was ten years ago. Pay-offs must not only be promised, but their feasibility demonstrated. The Space Shuttle, for example, succeeded in getting through Congress largely as a result of the economies that could be demonstrated for a re-usable space vehicle, and its potential commercial viability.

The changing environment is further reflected in the uncertainty over the future of NASA, itself partially a victim of its own success. Some claim that the agency should now shift its concern from the means to the goals of space activity, helping to build what one enthusiast calls "the new space America."

Others feel that NASA's responsibility should remain essentially exploratory and experimental, although most space scientists seem to agree that the agency should remain responsible for both the basic sciences and the investigation of its implications, since the former will only thrive if conducted in a symbiotic relationship with the latter.

At present the administration in general—and President Carter in particular—seem uncertain about the direction in which NASA should turn. A study of the national space effort conducted as a result of a presidential memorandum last year by Dr Norman Brown, Secretary of State for Defense, is said to have disappointed the administration in its conclusions.

More significant for space science will be a "public declaration" on the future shape of civil space activity, including NASA, which is currently being prepared by Dr Frank Press's Office of Science and Technology Policy. Some form of statement from OSTP is expected next month; but a renewed commitment to major programmes in space still seems a long way off. □

Fermilab director resigns over funding

In an effort to stabilise the funding of high energy physics (HEP), the US Department of Energy has decided to recommend that the HEP budget should be kept at a constant value of \$300 million (in 1979 prices) over the next few years.

According to the department, this sum—which breaks down into \$200 million for operating costs, \$40 million for equipment, and \$60 million for construction—will guarantee an active HEP programme based on three national centres, the Brookhaven National Laboratory on Long Island, the Fermi National Accelerator Laboratory in Illinois, and the Stanford Linear Accelerator Center (SLAC) in California.

However, although the department's proposed commitment is considerably higher than two years ago, when the HEP budget dropped to about \$240 million after reaching a peak of about \$500 million (both in 1979 prices) in 1970, it is still less than many scientists would like. And in protest at the department's decision not to speed up the construction of the energy doubler at Fermilab, Dr Robert Wilson, director of the laboratory, has carried out a threat made two months ago and submitted his resignation.

The Department of Energy's decision to keep HEP funding constant at a level slightly higher than the \$290 million proposed for fiscal year 1979 was taken after long and detailed discussion with the high energy physics community, in particular over the construction of the 400 GeV proton-proton colliding beam facility (ISABELLE) at Brookhaven which the department has proposed should start in 1979.

"Before agreeing to support ISABELLE, I asked what would make sense in terms of a long-term high energy physics programme?", Dr John Deutch, director of the department's Office of Energy Research, said last week. "I was not prepared to support the construction of a major new facility unless it was in the context of a balanced and aggressive high energy physics programme." Dr Deutch said that the decision to maintain a constant budget in real terms over the next few years was consistent with the consensus of the high energy physics community over the type of support that was required, and that it would provide some stability for future planning. A similar scheme was also being developed for funding nuclear physics.

The decision was welcomed by Dr Sidney Drell, deputy director and chairman of the department's High Energy Physics Advisory Panel (HEPAP), who pointed out that ever since the Ramsey report of the early

1960s, physicists have been asking for a stable basis for long-range planning. "Stable funding expectations will be very useful to us in terms of allocating resources, particularly in view of the fact that major HEP instruments can take seven years or so to build", he said. He added that the general level of funding was only "the minimum viable level" compatible with a three-centre programme, and there would still be many opportunities lost for good physics. According to Dr Drell, the proposed funding levels represent a 25% drop in operating funds for HEP facilities from their peak at the end of the 1960s.

Dr Wilson's decision to resign as director of Fermilab is a result of his failure to persuade the Department of Energy to bring forward the construction of the energy doubler, which by adding a second ring of superconducting magnets will eventually enable Fermilab both to save power costs and to reach energies of 1,000 GeV or more. Although the department is proposing to allocate \$10 million towards construction of the doubler in the fiscal year 1979, Dr Wilson had asked for

\$35 million, which would have been sufficient to complete the project during the year.

In his letter of resignation to the Universities Research Association, which runs Fermilab, Dr Wilson said that current restrictions of funding meant that the laboratory was operating at about half its potential capacity, a predicament that was particularly serious in view of the relatively high funding enjoyed by the European Centre for Nuclear Research (CERN) in Geneva, which recently brought its own 400 GeV accelerator into successful operation.

"Our scheme to leapfrog CERN's financial advantage by increasing the Fermilab proton energy to 1,000 GeV through the application of superconductivity has been confounded by indecisive and subminimal support," Dr Wilson said. He added that he had felt he was unable to continue to give the impression that he could responsibly direct Fermilab without a substantial increase in funding.

Although Dr Wilson is resigning as director, he has said that he intends to remain at Fermilab to work on the energy doubler project.

David Dickson

Salyut-6 used for weightlessness experiments

THE long sojourn of cosmonauts Yuri Romanenko and Georgii Grechko aboard Salyut-6 represents far more than an attempt to recapture the space endurance record. Soviet space planning has always been based on the idea of permanent orbital stations, indeed, Tsiolkovskii, "the father of Soviet cosmonautics" envisaged such stations as a *sine qua non* to manned lunar or interplanetary flight. The rumours which followed the Soyuz-11 disaster, which attributed the cosmonaut's deaths to the effect of prolonged weightlessness, were traumatic to space planners and amateur enthusiasts alike, and although subsequent investigations proved that the tragedy was in fact caused by a defective seal and consequent depressurisation, research into the physiology of weightlessness is a major concern to the Soviet manned space programme.

Unfortunately, weightlessness research is something which must largely be carried out *in situ*, and there is little scope for ground-level simulation. A 'hydro-weightlessness' tank is used to train cosmonauts for the difficult mechanical operations of station maintenance. Poland, as part of its contribution to the *Interkosmos* project, is said to be working on the biomedical effects of weightlessness, and an interesting experiment was recently

'You did say any kind of moral support, comrade!'

completed in Leningrad where for six months 18 volunteers lay "in a very inconvenient posture, with their feet several degrees higher than their heads", able to wash, shave, eat, and read, but "only allowed to turn from side to side, without rising even a little".

That experiment, which was presumably intended to simulate space-flight demineralisation, proved, according to its scientific director, Professor Leonid Kakurin, to be a great success.

Once the volunteers resumed ordinary life, their physiology quickly returned to normal, so that, according to Kakurin "space flight is not limited to six months. The human organism has genuinely unlimited possibilities".

On board experiments, however, are the only sure way of determining the effects of weightlessness. The biological programme of Salyut-6 includes both human and non-human tests. Certain of the latter seem somewhat esoteric—as, for example the result that tadpoles hatched in space swim in spirals, while earth-hatched tadpoles swim in a more "disorderly" manner. Other Salyut-6 experiments, monitoring the total effect of space rather than weightlessness alone, include the Franco-Soviet Cytos experiments on micro-organism cell division, a genetic investigation using *Drosophila* (banned from Soviet research at the height of Lysenkoism) and the somewhat ominously named "Medusa" experiment which compares the effect of space-flight on biopolymers in and outside the station.

The main source of medical data is, however, the on-board monitoring of cosmonauts. The Salyut-6 tests have included electrocardiograms, encephalograms and rheograph and manometer investigations, used at "rest" and after exercise on the "running track" and "veloenergometer". A special self-contained microanalysis kit was used to enable the cosmonauts to take samples of each other's blood; these were returned to earth by the Soyuz-26 craft.

The possibility of returning specimens in this way has greatly extended the facilities for maintaining the cosmonauts' health and well-being. Similarly the use of unmanned supply rockets will enable any necessary medicines to be taken into orbit. Progress-1 did, in fact, carry a replacement medicine chest—since although the original one had not been breached, it was felt that certain medicaments might have grown stale and lost their efficacy.

The use of replacement crews and supply rockets, however, has far more significance to cosmonaut health than simply that of keeping the life-support systems operative and the supplies recharged. The Salyut-6 planners have laid great emphasis on the physical comfort and psychological well-being of the cosmonauts. Station noise has been reduced by siting the motors "further astern" and installing "quieter switches". A shower has been installed (a triumph of ingenious design) and semi-rigid spacesuits are used for EVA which are said to simulate gravity by directing pressure to the lower parts of the body. The on-board menu includes over 60 named brands of food.

Nevertheless, all is not entirely

happy aboard Salyut-6. The TV set ferried up by Progress-1 was said to be urgently needed, to keep the crew in touch with world events. One cosmonaut mentioned that after 45 days in orbit there was a need for "any kind of moral support"; it was a great boost, he said, to know that the completed experiments returned for processing via Salyut-26 had turned out well. Clearly, one of the main problems of small-crew long-term space-stations is

likely to be that of psychological isolation—a factor which will undoubtedly increase as such stations become a matter of routine rather than headline news. One can only hope that in the future, relieving or supply crews will be less careless than Dzhaniybekov and Makarov, who in the excitement of undocking from the first four-man Salyut-link-up left behind the letters home of Romanenko and Grechko.

Vera Rich

USSR moves to protect rare animals

Vanishing species: the Amur tiger . . .

and goral

THE Soviet Union is preparing new legislation governing the conservation of rare fauna and restrictions on hunting. The December 1972 Resolution of the Central Committee and Supreme Soviet "on increasing the protection of nature and improving the use of natural resources", placed an emphasis on ecology that had been largely lacking in Soviet official thought, but so far its provisions have proved impossible to implement.

According to N. Eliseev, head of *Glavokhota* (Principal Hunting Trust) of the Russian Soviet Federative Socialist Republic (RSFSR), the poaching of rare and protected species is still rife. The RSFSR is by far the largest of the Union Republics, comprising Russia proper and the major part of Soviet Asia. Eliseev's department is thus responsible for 80% of all fur-bearing animals and 90% of all bird-life in the Soviet Union, including such rare and vanishing species as the Amur

tiger, the goral and the desman (source of musquash).

Hunting is still an important industry (since in much of the Soviet Union fur is a necessary rather than a luxury article) and it is governed by a somewhat complicated system of inspections and licences. But the poachers often manage to circumvent the various controls by making rapid safaris in fast cars and motor boats. Poaching, or at any rate, breaches of the hunting regulations on the part of licensed hunters, are common.

The new laws, says Eliseev, "will intensify the protection of wild animals, birds, fish and other fauna". Presumably this means (though he does not say so) severe penalties for poachers and dishonest hunters. Eliseev, however, stresses the positive approach to conservation, demanding a fundamental change in social attitude: "An end must be put to the consumer attitude towards nature". □

Germany's energy plans

THE West German government presented its latest programme to safeguard Germany's future energy supplies last December. An important feature of the programme concerns the efficient use of energy, especially for use in private households which accounts for the largest share of all Germany's energy consumption.

As heating makes up for 80% of private consumption, in future all new buildings will be legally required to conform to building regulations aimed at improving insulation. The government is also encouraging private owners to improve the insulation of existing buildings by offering them grants of 25% of the initial cost of improvement up to DM12,000 per purchase (£1=4DM) over the next five years. The grant also applies to the installation of solar collectors.

The new energy programme is clearly in favour of nuclear energy. Without it, the government feels that it could not guarantee an electricity supply in the long term. But just how much nuclear power station capacity is necessary is a matter of dispute particularly amongst the governing parties.

In future, however, new nuclear power stations will be sanctioned only if the problems of radioactive waste

disposal are solved. And the German view is that this can only be done by building a central plant to reprocess the spent fuel elements and to take care of the final disposal of radioactive wastes.

A site for such a plant has been chosen at Gorleben but the local population are protesting about its construction. So at the moment additional storage ponds are being built to store spent fuel elements from the power stations. The basic commitment to nuclear energy of both the federal government and the parties in the Bundestag will, therefore, only be realised if the radioactive waste disposal problem is solved.

However, the German government is also looking to coal for future energy needs. But German pit coal is very expensive and the present production of 90 million tonnes per year can be maintained only with considerable state subvention. Government and industrial research into non-nuclear energy sources is also being strengthened, the conversion of coal into other products being central to the government's programme. Research on alternative energy sources, such as solar and wind energy, is also receiving government support.

Werner Gries

World Bank's new health commitment

HAVING for years fought shy of involving itself in activities concerned with health, the World Bank has now taken a second step in the opposite direction—the first being its co-sponsorship of WHO/UNDP Onchocerciasis Control Programme (OCP) in the Volat River Basin. The new commitment was confirmed at a meeting at the beginning of February at WHO Headquarters in Geneva, with a 'memorandum of understanding' between the same three partners as co-sponsors of the Special Programme for Training and Research in Tropical Diseases. In general, the arrangement follows the same lines as that for the OCP, the Bank being responsible for administering the Tropical Diseases Research Fund, contributed by governments and organisations for projects to be executed by WHO and UNDP.

As expected, the cooperating parties' interests will be coordinated by a Joint Consultative Board. The board is expected to hold its first meeting in November this year. Its 30 members will include 12 representatives of governments, selected by the contributors; 12 selected by WHO's Regional Committee from among those countries directly affected by the diseases, or supporting the fund with scientific and technical assistance; three from among cooperating parties not otherwise represented; and one each from three sponsors of the programme. The latter will also have their own standing committee, meeting twice a year, concerned with technical and financial oversight of the programme.

As in the case of the OCP, there will be a scientific and technical advisory committee, concerned not only with advice on these aspects of the programme, but also with continuous independent evaluation of all programme activities. The 15 to 18 members of this committee will serve in their personal capacities, covering the whole range of biomedical and other disciplines with which the programme is concerned. The initial impetus will be maintained by interim meetings of the various groups before their formal establishment in November. A programme coordinator at the headquarters of the WHO will be responsible for the management of the programme.

As to financing, the meeting ended with some \$11 million pledged by various donors for the current year's activities. Moreover several large donors indicated that they would be making longer term pledges to cover at least the next five years of the programme.

Peter Collins

Sighting the Yeti's relatives

FOLLOWING reports of a possible "Loch Ness" monster in Lake Kos Kol, Soviet scholars have postulated a possible "relation" of the Yeti. The Institute of Language, Literature, and History of the Yakut Branch of the Academy of Sciences of the USSR has collected numerous accounts of sightings of a creature known locally as the "Chuchunaa", a name which apparently is connected with the Yakut word for "fugitive" or "outcast".

According to informants, the Chuchunaa is over 2m tall, uttering deerskin, and is unable to talk, uttering only a piercing whistle. He is described as a meat-eater, and is said to have the habit of creeping up to settlements and stealing food. When the Chuchunaa sights a hunter or reindeer-herder, he usually takes flight, but on occasion, it is said, will pick a fight. (No data have been released as to the outcome of such encounters.)

The best sightings of the Chuchunaa seem to occur in summer at dawn or late dusk. Hunters, mushroom pickers and the like who are out at this time have reported seeing a wild man, with arms hanging below his knees, barefoot and dressed in skins. The face is said to be large, human-like but very

dark, with a protruding brow "like a peak", long matted hair, and a full beard—larger than that of a man. At such times, the Chuchunaa has been reported to be feeding on berries, tearing them from the bushes with both hands.

According to Semen Nikolaev, a senior staff member of the Yakut Branch of the Academy, "almost all witnesses speak of the Chuchunaa as a reality without the fantastic detail so characteristic of legends". (To a Westerner, the above description seems very much the stuff of which legends are made—and one cannot help wondering whatever Nikolaev would classify as "fantastic"—Baba Yaga riding on her pestle, maybe?). Since the details of many sightings coincide, Nikolaev and his colleagues seem willing to admit the postulate that the Chuchunaa represents the last surviving remnant of the "Palaeoasiatic aborigines" of Siberia, who have retreated to a last refuge in the upper reaches of the Yana and Indigirka rivers. Indeed, since the last reliable sighting dates from the 1950s, some of the more pessimistic experts think that the Chuchunaa may have died out during the last two decades.

□

Chinese exchanges easier

CHINA has begun trying to achieve the four modernisations—agriculture, industry and defence with science and technology as the 'key'—in accordance with the policy laid out in Chairman Hua's Political Report to the Party Congress last August. The plan for agricultural modernisation over the next three years was revealed on 26 January in a report to the third national conference on agricultural mechanisation.

In spite of these moves towards achieving China's new goal, however, discussions are still taking place on the future of many aspects of national life. In education, for example, it has been reported that the advice of a top leader has been sought on a question not resolved at ministry level. It is unlikely, however, that this concerned the egalitarian drives to set up an 'open university' via the national television network and to make universal by 1985 middle-school education in the cities and junior middle-school education in rural areas. The

overall picture, however, is that progress in education is regaining momentum; an All-National Conference on Education will be held after the one on science in

China is also implementing plans to increase international academic exchange. The situation report delivered last December by Fang-Yi, Vice-President of Academia Sinica, reiterated that China is striving to learn advanced science and technology from foreign countries whilst keeping to the principle of self-reliance and independence. Already, some scientists of Chinese origin have been led to believe that they will be invited to China at some stage in the near future for short term teaching and/or research. And there is also no question that China will employ many foreign experts.

An ordinary tour of China can be simply arranged. Last month's issue of *China Reconstructs* published a guide for prospective applicants, either single or in a group. A technical visit, such as a visiting professorship, will probably

have to go through personal connections or organisations such as the revitalised Chinese Scientific and Technical Association, whose acting chairman is Chou Pei-yuan of Peking University. Chou (a physicist) may in fact be regarded as in charge of academic matters in research and education, and Fang Yi as in charge of political and general concerns.

The Japanese, however, have gone some way to taking the initiative in fostering exchange with China: an Association for Japanese-Chinese Scientific Exchange was founded in Tokyo last December. The French also recently signed a Science and Technology Agreement with China covering, amongst other cooperative schemes, the exchange of scientists. Incidentally, M Barre's state visit to China also resulted in another development: Hua's acceptance of an invitation from Giscard d'Estaing to his country. That will make France, an old friend of China's, the second country in the world that a Chinese Communist Party Chairman has ever visited.

T. B. Tang

Most countries have their own units of length, weight and volume, and several systems for measuring temperature have been used in different parts of the world. These different units present difficulties to travellers, and to the communication of scientific results between nations. Many years ago, on a walking holiday in Sweden, I set off for a village which a signpost said was three miles away. After striding along at a reasonable pace for nearly two hours I saw a second sign saying that I still had to cover two miles. Thus I learned that one Swedish mile was equal to six English miles.

On another occasion at a seaside resort in Denmark I saw a notice which said that the temperature of the sea was 16 degrees. I hesitated to bathe, for this seemed a little chilly, but when I overcame my reluctance I found the water warmer than expected. The temperature had been recorded on the Réaumur scale, and corresponded to 20 degrees Celsius, or 68 degrees Fahrenheit.

It seems sensible to come to some agreement so that the same units are used internationally. For a long time scientists in Britain and many other countries have followed two systems, metric in the laboratory, and 'traditional' outside. We are now trying to change and are using the metric system everywhere. Unfortunately, this rational change makes life less interesting. It was always pleasant to find maunds and seers in India, and quite easy to make the necessary conversions. I was glad to find recently in Mauritius that land

is still measured by the arpent (1.043 acre). British farmers are urged to go metric, but they still think, and usually talk, of yields in hundredweights per acre, though the bushel has largely disappeared.

Uniform units

KENNETH MELLANBY

Those of us brought up in the laboratory on what are now old-fashioned metric units find the SI system difficult to use. I really cannot understand why I must stop talking about cubic centimetres, for this is a sensible unit and is easily understood. The change to millilitres seems to be unjustified.

Even more important than using the same units (for these can easily be con-

verted) is to have the same meaning for words. In Britain and most of Europe the billion has always been 10^{12} . North Americans, thought by Europeans to be prone to exaggeration, give the word the value of only 10^9 . I despair of converting Americans back to the correct use of the term, and see no reason to follow their bad example. I therefore believe that the term has become so ambiguous that it should no longer be used. As an editor I ban it from my journal. Recently I have been shocked to see that *Nature* has allowed the word, with its American use, to appear in its columns. I hope that all my readers will support my campaign for the total abolition of the billion in any form.

In Britain we have even decimalised our currency, and lost our useful shillings and pence. One more exotic coin, the guinea, has not yet disappeared entirely. It is still used for selling expensive race horses and to pay for private medical treatment. The guinea was originally the same as the pound sterling, and was made up of twenty shillings. However, from 1717 gold sovereigns (pounds) made of Guinea gold from West Africa were found to be so pure that they were officially valued at twenty-one shillings. I recently received a bill for dental treatment for fifty guineas; this was converted by a young clerk into £55. She apparently thought that with decimalisation the guinea was now £1.10 instead of the original £1.05. No wonder people think that decimalisation has helped to increase the rate of inflation.

correspondence

USSR bars Israeli scientist

SIR,—We wish to protest against the discriminatory practices of the Soviet Union towards Israeli scientists wishing to participate in international scientific meetings held in the USSR.

The Fourth International Meeting on Ferroelectricity (IMF-4) was held in Leningrad on 18-23 September 1977. The meeting was organised by the Academy of Sciences of the USSR under the sponsorship of the International Union of Pure and Applied Physics, the International Atomic Energy Agency, and the European Physical Society. We had both delivered papers at the Third International Meeting on Ferroelectricity in Edinburgh in 1973, and we were looking forward to participating in IMF-4. However, at every stage—soliciting information regarding the meeting, inquiring as to the status of our submitted manuscripts, attempting to obtain an entry visa to the USSR—we, and several other Israeli colleagues, encountered incredible obstacles, which ultimately led to our being unable to attend the meeting. Our individual experiences were as follows:

Sidney B. Lang submitted the abstract of a paper on 29 March 1977 to Professor G. Smolensky, Chairman of IMF-4 in Leningrad. Receipt of the abstract was never acknowledged, nor was information sent regarding the status of the paper. After seeking the assistance of Professors W. Cochran (University of Edinburgh) and W. J. Merz (R.C.A., Zurich), one of us (S.H.) received a letter from Professor Cochran, dated 30 June 1977, stating that he had received a cable from Professor Smolensky that the papers of Lang and Havlin had been accepted. Because of the impossibility of an Israeli receiving a visa to the USSR without first travelling to Western Europe, and lacking any official documentation from the Organising Committee that could be used in requesting a visa from Soviet embassies in Europe, Lang was forced to withdraw his paper on 25 August 1977. On 16 September 1977, two days before the meeting opened, Lang received the 'second circular' about the meeting, mailed from Romania on 30 August. This circular bore no date, but it specified a number of deadlines between 30 April and 18 June.

Shlomo Havlin submitted the abstract of a paper on 7 February to Pro-

fessor Smolensky and as in the case of Lang, heard nothing. On 8 July the Secretary General of IUPAP, in response to requests for assistance by the Israel Physical Society, cabled that Havlin's paper was included in the meeting programme, and that he need only apply to Intourist for an entry visa. On 9 August, Havlin arrived in Paris and immediately applied for a visa at the Intourist office. At every subsequent visit to the office as well as to the Soviet Embassy, he was assured that his visa would be issued "tomorrow". The seemingly sincere promise that the visa would surely be forthcoming led Havlin to remain in Paris beyond 8 September when he had planned leaving for Leningrad. On 11 September, still with no visa, Havlin realised there was no point in continuing his battle and left Paris.

Although the organisers of the Leningrad meeting had made firm promises to IUPAP, Professor Cochran, and Professor Merz, the Soviet authorities refused to issue a visa. From our experiences, it is obvious that Israeli attendance at this international meeting was prevented by the Soviet Union.

We suggest the following to our fellow physicists and to the officials of physics organisations:

- International organisations should not sponsor meetings in the USSR without firm guarantees from the Soviet government that these meetings will be open to citizens of all nations without exception. Promises from Soviet organising committees should not be accepted *in lieu* of official Soviet government commitments. Scientists should write to the officers of the physics organisations to which they belong, demanding that this principle be strictly adhered to.
- Scientists should refuse to attend meetings in the USSR unless they are certain that the Soviet government has, in fact, guaranteed that the meetings will be open to citizens of all nations without exception.
- Letters should be written to the Soviet organisers of IMF-4 protesting the discrimination that was practised towards Israeli scientists. The organisers were:

Chairman:

Professor G. Smolensky
A.F. Ioffe Physico-Technical Institute
Academy of Sciences of the USSR
Leningrad, 194021
USSR

Vice-Chairmen:

Professors L. Shuvalov and I. Zheludev
Institute of Crystallography
Academy of Sciences of the USSR
Moscow, 117333
USSR

We believe that the holding of meetings without firm adherence to the above principles is totally incompatible with the international character of science and scientific research.

Burying high-level wastes

SIR,—The disposal of intermediate and low level radioactive wastes in salt deposits of Permian (about 220 Myr) age is proceeding and proposals have been made to treat high level wastes in a similar fashion. When evaluating the suitability of these formations for this purpose, the proponents stress the antiquity, aseismicity and availability and conclude that they are "extremely stable" (*The Management of Radioactive Wastes*, IAEA, Vienna; 1977). Most geologists, however, would consider that rocks of this type are very unstable. Widespread halokinesis is well-documented and the role of diapirism in the formation of stratigraphic traps favourable for oil and gas accumulation is particularly significant.

In rocks containing potassium the radioactive decay of ^{40}K forms radiogenic ^{40}Ar , resulting in a high relative abundance of this isotope in the atmosphere. In early experiments designed to evaluate the possibility of using this decay scheme to measure geological time the ^{40}Ar concentrations in samples of evaporite were measured. In almost all cases it was found that significant argon loss had occurred. This was attributed to the instability of these strata and their susceptibility to dissolution by fluids (such as percolating ground water) and subsequent recrystallisation which had allowed the escape of ^{40}Ar . It is not usually possible to detect these effects by examination of the rocks in hand specimen or thin section. For instance, although Suess (1948), consulted "specialists for salt mines" his analyses demonstrated that

the samples he had been given had been recrystallised in recent times (Houtermans, F. G. in *Potassium-Argon Dating*, 5 Springer-Verlag; 1966). As a result the evaporite minerals have not subsequently been routinely employed for K-Ar dating.

The apparent ease of escape of radiogenic daughter isotopes from salt formations, particularly in recent times, and the alarming implications in the event of a containment failure, seem to require a thorough re-evaluation of the stability of these beds. Before any final decision on high-level radioactive waste disposal is reached, a systematic programme of argon measurements might provide a simple means of determining the extent of this phenomenon and enable its significance to be assessed.

Alcohol in Britain

SIR,—J. A. Spring and D. H. Buss's account of three centuries of alcohol in the British diet (*Nature* **270**, 567–72; 1977) gives good evidence for the high intake of beer in Britain in years gone by. But may I add a comment to the statement that "there are no obvious reasons" for the steady decline in beer consumption during the eighteenth century (p 567)? It is that the increase in tea-drinking in that period was very much greater than taxation figures suggest.

Genuine China tea remained expensive throughout, but a great deal of what was consumed was in fact adulterated with the dried and chemically treated leaves of such trees as hawthorn, sloe and ash (known in the trade as 'smouch'), or with used tealeaves purchased at small cost from the kitchen-maids of the wealthy. The cheapest teas contained little else.

Tea-drinking increased steadily during the century in all classes of society, especially among women. For the poorest families in the South and Midlands, there was a reason for this increase. Enclosure and the high cost of fuel deprived them of soups and the cheapest cuts of meat, which required long cooking. Crude tea without milk was the only warm comforting element in a diet that otherwise consisted of bread, cheese and occasionally cold, fat bacon.

The changeover from beer to tea as the common mealtime drink was well under way during the 1730s and 1740s. And in 1784 the high import duty on tea was at last lowered to a nominal sum on the grounds that "tea has become an economical substitute to the middle and lower classes of society for

malt liquor, the price of which renders it impossible for them to procure the quantity sufficient for them as their only drink".

Dietary lipids and heart disease

SIR,—May I point out some fallacies in Dr John Rivers' review (*Nature* **270**, 2; 1977) of the so-called 'lipid hypothesis' of coronary heart disease (CHD)?

●The Finnish trial of Miettinen *et al* did show a notable decrease in mortality for males on a diet relatively high in poly-unsaturated fat. During the transcription of the mortality data from the original paper (Miettinen *et al*, *Lancet* **2**, 837; 1972) to the article discussed by your reviewer (Mann, G., *N. Engl. J. Med.* **297**, 646; 1977) an error was made which obscures the difference in mortality between the experimental and the control period ($32.00 + 2.84$ does not equal 38.84). It is disappointing that neither the editor of the *N. Engl. J. Med.* nor your correspondent noticed this.

●Unlike cigarette smoking, atmospheric pollution has not been shown to be an independent risk factor for CHD.

●Poly-unsaturated margarines do not necessarily contain *trans* fatty acids. The most popular Dutch brand of poly-unsaturated margarines contains 60 to 65% *cis-cis*-linoleic acid and 0% *trans* fatty acids. Its British equivalent ('Flora') has 6% of its fatty acids as *trans* isomers, which is similar to the proportion found in butter (data by courtesy of Unilever Research, Vlaardingen, The Netherlands).

●Epidemiological data overwhelmingly point in the direction of a relation between consumption of saturated fat and CHD (Keys A., *Atherosclerosis* **22**, 149–192; 1975). The Masai are only a notable exception. Incidentally it should be stressed that cause-effect relationships cannot be proved or disproved by such comparisons between tropical and western populations, but only by controlled experiments.

●Few people with original or heretic ideas in the food-health field are finding it really difficult to obtain research funds or publicity. Dr Mann himself, as the recipient of a career investigatorship from the National Heart, Lung and Blood Institute, is a case in point.

Nutrition is a billion-dollar business, a favourite subject for the media and an almost religious pre-occupation for a large part of the public. In view of these pressures, scientists bear a heavy responsibility to keep their data straight. In my opinion neither Dr

Mann nor your correspondent have succeeded in this.

Intelligence is more than IQ

SIR,—I was interested in the letter by Brian J. Ford (5 January, page 7). I agree very fully with him of course, that the controversy is confused by the impossibility of obtaining measurements independent of cultural background. It is a great pity that so much more ink is being spilt in trying to prove that the heredity factor is unimportant, which for all I know may be true, than in the effort to raise all cultural backgrounds to an optimum level.

I would like to amplify Mr Ford's comment on the need for producing criteria which would reconcile mental measurements with the realities of life. What is practically accepted as intelligence depends to a very much more limited extent on IQ than is usually recognised. Thus IQ measurements often depend largely on the accurate understanding of the exact meanings of words and on the solving of logical problems. Solving real practical problems may often involve no language at all and in nearly all cases is concerned with the realities of a complicated situation rather than with the exact words by which this should be described. Furthermore the problems presented are unnatural in that the examinee knows that he has all the data required and that every datum is correct.

In real-life problems one never knows in advance whether one has all the necessary data and often is unsure whether the available data are right. Practical intelligence is therefore concerned with the judgement of whether sufficient data are available, with an understanding of how to obtain fresh data when necessary and then assessing the correctness or otherwise of the vital parts of the data available. This will involve persistence—in few practical situations must one solve 12 problems in 36 minutes—an ability to avoid prejudice, and some capacity for lateral thinking as well as IQ. Having satisfactorily solved all the practical problems the logical problem is nearly always trivial.

While a high IQ is valuable in a number of ways and probably has some correlation with the other factors I have mentioned, it is most unfortunate that it is so widely regarded as more important than it is, merely because it is so easy to put it in numerical terms.

H-2 and HLA antigen structure

from Jonathan Howard

THERE have recently been remarkable developments in understanding the structure of the antigens of the major histocompatibility complex (MHC). For a variety of reasons the structures of these molecules are of consuming interest. First, they are powerful antigens; T cell responses to MHC antigens are one or more orders of magnitude stronger than other antigens. So abundant are T cells reacting to MHC antigens that it is at least debatable that the entire T cell pool is committed to the recognition of these structures.

Serologically the MHC antigens are exceedingly complex; each molecule, particularly those specified by the human HLA-A and HLA-B genes, and their mouse homologues H2-K, and H2-D, carries multiple antigenic determinants which constitute in sum the families of specificities that identify each MHC product. This serological complexity implies a genetic polymorphism of unprecedented extent. The presence of multiple alloantigenic specificities on a single molecule probably means that there is not just a single highly polymorphic site but several independently polymorphic regions on each molecule. Comparative sequence analysis of H-2 and HLA molecules available for the past couple of years (see *News and Views* 261, 189; 1976) suggests that the antigenic differences between H-2 and HLA allotypes reflect multiple amino acid substitutions at least at the NH₂-terminus, and tryptic peptide analysis of whole H-2 molecules shows that amino acid variation between allotypes must extend throughout a large portion of the molecule (Brown *et al. Biochemistry* 13, 3174; 1974). The origin and maintenance of such complex allotypes is a genetical problem of considerable interest in its own right (Silver & Hood in *Cont. Topics molec. Immun.* 5, 35; 1976).

MHC structures apparently corresponding to those identified as polymorphic antigens are also involved in the recognition by T cells of conventional

foreign antigens (Munro & Bright *Nature* 204, 145; 1976; Doherty *et al. Transplant. Rev.* 29, 89; 1976). Recognition of self MHC structures in either a native or altered form is essential for the induction and expression of specific T cell function to other antigens: this phenomenon of 'MHC restriction' implies either that T cells carry separate receptors specific for 'self' MHC structures and for foreign antigen (the 'dual recognition' hypothesis), or alternatively, foreign antigen is captured on the cell surface and presented to reactive T cells in some form of molecular association with self MHC structures (the 'altered-self' hypothesis).

It has been known for some time that the HLA-A and B molecules, and H-2K and H-2D molecules are physically associated with β_2 -microglobulin, a polypeptide with a molecular weight of 12,500 which in both sequence and intrachain disulphide bridge structure is homologous with a single domain of immunoglobulin. This has provoked speculation that the antigenic polypeptide chain of H-2 and HLA molecules might itself have sequence or structural homology with immunoglobulin, although this was not convincingly demonstrated by the first NH₂-terminal sequences that became available.

Detailed structural studies, primarily on the HLA-B7 molecule, by Strominger and colleagues (Strominger *et al. Proc. 3rd Int. Cong. Immun.* 1977, in the press) have given extraordinary new insights into the molecular organisation of a major transplantation antigen. Most striking of all is the unambiguous demonstration that this molecule does indeed have significant sequence and structural homology with immunoglobulin. This leaves little doubt that, as has been suggested before, the two molecular systems have had an, albeit distant, common precursor. The association of HLA with the Ig-domain-like β_2 M polypeptide may therefore legitimately be considered in the same context as the association of the evolutionarily divergent but homologous light and heavy chains of immunoglobulin.

The HLA-A and B molecules are

typical transmembrane glycoproteins with a molecular weight of about 45,000 having a strongly hydrophilic C-terminal intracellular segment, a short hydrophobic segment presumably responsible for membrane insertion, and a long extracellular hydrophilic segment representing about 80% of the molecule. The extracellular segment is folded into two non-intercalated disulphide-bridged loops and a free N-terminal segment. Each intrachain loop encloses a segment of approximately the same length as the intrachain loops of Ig domains. Sequence determinations near both the disulphide bridges reveal marked homology with immunoglobulin V_H sequence around the disulphide bridge at residue 95. Furthermore the N-terminal sequence of HLA-A and HLA-B, although not itself looped by a disulphide bridge, shows a significant homology with the same V_H region after appropriate alignment.

It is difficult to escape the conclusion that the extracellular portion of HLA is composed of at least two and possibly three mutually homologous domains, all showing significant homology with immunoglobulin, and two of them looped by disulphide bridges as in Ig. A peculiar aspect of the sequence homology between HLA and the V_H of Ig is that the relevant sequence runs from the C-terminal Cys of the first intrachain disulphide bridge toward the N-terminus in the V_H, and is thus entirely included in the looped segment; in HLA the homologous sequences run from the N-terminal Cys of the two intrachain bridges towards the N-terminus, and are thus entirely excluded from the looped segments. This important difference may well indicate that the similarity in domain structure between the two classes of molecule is more apparent than real; nevertheless the overall appearance remains of two, however distantly, related molecular species.

Although the residues responsible for the serologically detectable alloantigenic activity of H-2 and HLA molecules have not been identified, it is tempting to relate the extensive sequence variation throughout the molecules to the newly

Jonathan Howard is at the Institute of Animal Physiology, Babraham.

recognised domain structure and argue that the alloantigenic complexity of the molecules is due to independent sequence variation in each domain. In this way it is possible to have unique antigenic specificities (private antigens) associated in different molecules with various clusters of other specificities (public antigens). It may be anticipated that sequence variation associated with serological activity will be found to be spread over many parts of the molecule.

It seems unlikely, however, that allo-antigenicity is the most significant aspect of H-2 and HLA molecules for all its genetical and clinical importance. The recent discovery of H-2 and HLA restriction suggests that polymorphic structures on these molecules play an important part in T cell induction by antigen in the normal animal. Of particular interest therefore, is the relationship between the structure of the molecules involved in restricted interactions and the process of restriction itself. The mouse H-2K^b mutant H-2K^{ba} is a variant of considerable importance because, with respect to H-2 restricted lysis of virus-infected cells the mutant H-2 molecule is essentially non-overlapping with the wild type. T killer cells raised against virus-infected cells in the wild type H-2K^b mouse will lyse appropriately infected H-2K^b targets but not infected H-2K^{ba} targets, and *vice versa*. Comparison of the structure of H-2K^b and H-2K^{ba} molecules by Nathenson and

colleagues (*Cold Spring Harbour Symp. quant. Biol.* **41**, 343; 1977) has shown a limited number of peptide differences, compatible with a single amino acid substitution.

Furthermore, preliminary alignment of the variant peptides in the tentative model for H-2K (which is less developed than that of HLA-B7) suggests that they lie in or near the first disulphide-bridged domain. A location partially overlapping with H-2^{ba} is suggested for the non-identical but similar variant H-2K^{ba}. These findings indicate that the specificity of H-2 restriction is determined by a relatively limited part of the H-2K molecule. Interestingly, the variants H-2K^{ba} and H-2K^{bd} are not yet distinguishable from H-2K^b by conventional serological techniques, yet both variants provoke the full range of T cell responses by the parental type. It seems, therefore, that the mutated sites in these two variants are different from the predominant antigenic sites recognised by alloantibody.

Such observations have important implications for altered self or H-2 modification theories. The fact that the differences between H-2^{ba} and H-2^{bd} lie in a specific segment of the H-2 molecule implies that this segment must be important in the process of structural modification of H-2 antigen. Since the principal obstacle to the acceptance of an H-2 modification theory of H-2 restriction is the lack of any molecular mechanism by which antigen-specific modification might

occur, the localisation of a restriction site in a molecule whose structural organisation is beginning to be known should obviously be taken very seriously.

For the time being, the domain structure, association with β_2 -microglobulin and Ig sequence homology of H-2 and HLA seem significant without carrying a clear message. Without evidence for clonal allocation of different H-2 or HLA molecules between lymphocyte subpopulations, there are no grounds for believing that the specificity of antigen recognition by lymphocytes is due to sequence variations in these molecules. Nevertheless the apparent similarity between the two molecules may suggest that H-2 and HLA molecules are receptors for something at the cell surface. An analogy might be drawn with the two polypeptide hormones insulin and relaxin which, markedly similar in conformation, and plainly homologous, have entirely different biological roles while both function as hormones. I find it tempting to consider the possibility that the structure of H-2 and HLA molecules will indeed prove to be related to the phenomenon of MHC restriction by structural modification. However that may be, it is clear that the primary functions of these extraordinary molecules must be sought in the membranes into which they are inserted, rather than in their remarkable but probably biologically irrelevant immunogenicity in allogeneic responses. □

Invertible DNA in phage Mu

from Martha M. Howe

INVERTIBLE DNA sequences in prokaryotic DNA were first detected in the early 1970s during analysis of DNA from bacteriophage Mu. Since then, the discovery that inversion of a DNA segment controls the phase variation of flagellar antigens in *Salmonella* (Zieg *et al.* *Science* **196**, 170; 1977) and that inversion of an insertion sequence affects expression of the *gal* operon in *Escherichia coli* (Saedler *et al.* *Mol. gen. Genet.* **132**, 265; 1974), have lent credence to the hypothesis that inversion of DNA segments may be a general mechanism for the control of gene expression. Only recently has the role of DNA segment inversion in Mu development and gene expression begun to be understood.

An invertible DNA sequence in Mu was discovered in several laboratories studying the DNA forms arising after denaturation and reannealing of Mu DNA extracted from the mature phage

particle (Bade *J. Virol.* **10**, 1205; 1972; Daniell *et al.* *Virology* **51**, 237; 1973; Waggoner *et al.* *Proc. natn. Acad. Sci. U.S.A.* **71**, 1255; 1974). The two structures observed are shown in Fig. 1. One form was completely double stranded except for non-hybridizing single strands—'split ends'—found at the right end of the molecule. These split ends contain host DNA sequences which differ in different phage particles (Daniell *et al.* *J. Virol.* **15**, 237; 1975). The second form contained not only the split ends but also a single-stranded bubble structure termed the G bubble, flanked on its left and right by duplex DNA, the α and β segments, respectively. Hsu and Davidson (*Virology* **58**, 229; 1974) demonstrated that this G bubble arose by reannealing of Mu DNA strands containing the G segment DNA in opposite orientations. They postulated that inversion of G segment DNA occurred by recombination between two short inverted repeat sequences located at its ends and that the inversion was catalysed by a phage-specified function

active in both prophage and vegetative states.

One puzzling observation made by Daniell *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **70**, 2153; 1973) was that the relative amounts of the two orientations differed in different phage populations. In DNA from lysates grown by induction of a lysogen both orientations of the G segment were present in approximately equal amounts; however, in lysates grown by infection 99% of the DNA had the G segment in one orientation, and this orientation was the same in all DNAs from lysates. The reason for this difference was not understood until experiments of Chow *et al.* (*J. molec. Biol.* **113**, 591; 1977) suggested that phage containing the G segment in opposite orientations might differ in their viability. This hypothesis was based on analysis of two classes of viable Mu phage containing partial deletions of the G and β DNA segments. Phage in one class were deleted for part of both the G and β segments and were unable to invert the G segment, pre-

Martha M. Howe is Associate Professor in the Department of Bacteriology at the University of Wisconsin, Madison.

Fig. 1 Structure of Mu DNA. Structures observed in electron micrographs of denatured and reannealed Mu DNA. The $xyy'z$ and complementary $x'y'yz'$ lettering in the G segment does not represent specific genes (Hsu & Davidson *Virology* 58, 229; 1974). The black boxes flanking the G segment represent the inverted repeat sequences which serve as the sites of recombination for inversion.

sumably due to loss of one of the inverted repeat sequences, demonstrating that the process of inversion of the G segment itself was not essential for phage viability. Phage in the second class had an intact G segment and were only deleted for part of the β segment, yet they were also unable to invert the G segment. Chow *et al.* (*op. cit.*) postulated that phage in the second class were defective; in the Mu-specific function needed to invert the G segment, which they termed the *gin* (G inversion) function. It was the unexpected finding that both classes of phage contained the G segment in the same orientation as that predominating in lysates grown by infection that led to the hypothesis that phage containing the G segment in the opposite orientation might be non-viable due to lack of expression of essential genes located within the G segment DNA. Further experiments in their own and other laboratories have proved the validity of these hypotheses.

Symonds and Coelho (*Nature*, 271, 573; 1978) find that in single burst experiments with non-deleted heat-inducible Mu lysogens only half the cells released viable plaque-forming phage on induction. This is expected if half the cells contained Mu prophages with the G segment in the non-viable orientation. Kamp *et al.* (*Nature*, 271, 577; 1978) confirm and extend this finding by testing populations of cells lysogenic for a heat-inducible Mu prophage for their relative ability to release plaque-forming phage on induction and for the orientation of the G segment in DNA extracted from phage particles produced as a result of induction. They found that the proportion of cells able to release plaque-forming phage was directly correlated with the proportion of phage DNA containing the G segment in the viable orientation. In a second experiment they demonstrated that

a Mu *gin*⁻ prophage could be complemented for inversion of the G segment by transient exposure of the cell to a Mu *gin*⁺ prophage. Two types of Mu *gin*⁻ lysogens resulted. The first released plaque-forming phage particles whose G segment was in the original viable orientation. The second released phage particles which could not form plaques and whose DNA contained the G segment in the opposite or non-viable orientation. Thus they have definitively demonstrated that the orientation of the G segment affects the viability of the phage particle.

Experiments by Bukhari and Ambrosio (*Nature*, 271, 575; 1978) reveal that the phage with the G segment in the wrong orientation are non-viable because they cannot adsorb to cells, whereas phage with the G segment in the viable orientation adsorbed to cells and replicated their DNA normally.

Mu genes whose expression might be determined by the orientation of the G segment have been identified in our laboratory. We have found that the essential genes *S* and *U* of Mu map within the invertible G segment. Although the functions of these genes have not been conclusively determined, several lines of evidence suggest that they may be involved in adsorption. First, serum blocking experiments indicated that the phage inactivating activity in anti-Mu serum was directed against the *S* protein of the phage particle. Second, Mu *S*⁻ and *U*⁻ phage which acquired an *S*⁺ or *U*⁺ phenotype by recombination with phage P1 often simultaneously acquired the host range of P1 (Toussaint *et al.*, private communication). These recombinants probably arose through exchange in the regions containing the G segment of Mu and a similar invertible segment of P1 which has extensive homo-

logy to the Mu G segment (Chow & Bukhari *Virology* 74, 242; 1976) and which may determine the host range properties of P1 (Toussaint *et al. op. cit.*).

The experiments described above indicate that the orientation of the G segment of Mu determines the expression of adsorption functions of Mu, perhaps by controlling the synthesis of the *S* and *U* proteins. Why should such relatively unrelated phages as Mu and P1 have homologous invertible segments and why should Mu have an invertible segment whose inversion makes the phage particle non-viable? Possible explanations were discussed at the Bacteriophage Meetings held at Cold Spring Harbor Laboratory last August. Normal genetic exchange by homologous recombination between ancestors of Mu and P1 might explain the invertible segment homology in the two phages; however, the lack of homology elsewhere in the phage suggests the intriguing possibility that the invertible segments may be able to translocate independently from one DNA to another. In this case Mu and P1 might have acquired the segment from a common source, or the segment present on one of the phages might have translocated to the other. The different lengths of the inverted repeat sequences of the elements in two phages in the translocated element suggests that changes may have occurred subsequently (Chow & Bukhari *Virology* 74, 242; 1976).

Why does Mu possess a function which impairs its viability. It may be pertinent to consider the organisation of the control system. Two possible simple on-off control mechanisms might exist. One is that postulated for the control of antigenic phase variation in *Salmonella* (Zieg *et al. Science* 196, 170; 1977) in which the promoter is present on the invertible sequence and the structural gene under its control is not. The second, perhaps more applicable to Mu G segment inversion, is one in which the structural genes are located in the invertible segment with the promoter outside. In both these cases the synthesis of the structural gene products would depend on the orientation of the invertible segment. A third possible organization is one in which the invertible segment may contain genes at each end which specify different adsorption proteins responsible for determining the host range of the phage. If the promoter for these genes were located outside the invertible segment such that only the genes immediately adjacent to the promoter were expressed, inversion of the segment might lead to expression of a different host range. The ability of the phage to alternate between two different host ranges might provide it with a selective advantage in natural populations. Such a model might be directly applicable to P1 since P1 DNA contains equal amounts of both orientations regardless of its mode of growth (Ohtsubo,

cited in Chow & Bukhari *Virology* **74**, 242; 1976). To apply the model to Mu it would only be necessary to postulate either that Mu might be defective in the second set of genes or that Mu phage with the G segment in the non-viable orientation are able to adsorb to other

bacterial strains which have not yet been tested. Further experiments will more completely elucidate the role of G segment inversion in expression of Mu genes and will reveal whether inversion of DNA segments comprises a general mechanism of gene control. □

How plants respond to stress

from Hamlyn G. Jones

THE plant hormone abscisic acid (ABA) has been invoked to explain a host of plant processes ranging from dormancy and leaf abscission, through flowering and fruit drop to the response of roots to gravity. However, it is as a stress hormone involved in the drought-induced closure of stomata, that there is the most complete evidence for a natural role for this hormone. The stomata are the chief control on water loss from plants, so that stomatal closure is an important mechanism enabling plants to survive in dry environments.

There is now evidence that the amount of ABA in tissues of many plant species increases rapidly when the plants are subjected to various stresses, including water deficits. Increased concentrations of ABA can be detected within 7 minutes of the start of a stress period and can increase as much as 40-fold over 4 hours. The evidence that this stress-induced ABA is involved in at least some of the natural stomatal movements is now overwhelming. Not only is the amount of ABA extractable from leaves generally related to stomatal aperture, but ABA applied to leaves usually results in rapid stomatal closure. Further evidence comes from work by Tal and coworkers at the University of the Negev on a wilted mutant of tomato (*flacca*) which does not close its stomata. This lesion was found to be due to a deficiency of ABA which could be overcome by supplying extra hormone.

Two papers in this issue of *Nature* (Itai *et al.*, page 652 and Itai & Meidner, page 653), provide further evidence of a role for ABA in stomatal physiology. These workers demonstrate, using microautoradiography of leaf or epidermal tissue supplied with ^{14}C -labelled ABA, that the hormone can accumulate at the presumed site of action—the stomatal apparatus.

This extends recent work by Loveys (*Physiol. Plant.* **40**, 6; 1977) who showed that although ABA does not appear to be synthesised in the epidermis it does accumulate in the epidermis

under stress. Nevertheless, there has not yet been an unequivocal demonstration that ABA accumulates in the stomatal apparatus during natural stress.

If the details of ABA accumulation are not yet proven, the mode of action of the hormone is even less certain. Changes in stomatal aperture are directly caused by changes in the balance between the internal pressure of the guard cells (specialised cells which surround the stomatal pore) and other epidermal cells. The high pressures necessary to open stomata arise from the active accumulation of osmotically active molecules and ions, especially K^+ . It is likely that ABA acts in some undetermined manner on the accumulation or retention of K^+ , as discussed by Itai and Meidner.

In spite of these recent successes in explaining stomatal movements in terms of ABA it is as well to remember that this is not the only mechanism involved in controlling stomatal movements. In the first place, so-called hydroactive closure can begin within a few seconds of changes of leaf water status; a response which is too rapid to involve a hormone such as ABA. Second, the hormone is probably not involved in the normal diurnal opening and closing movements found in most plants. Third, there are several reports of the involvement of other naturally occurring compounds in the regulation of stomatal aperture, particularly under stress. Most evidence has been adduced for an involvement of all-*trans*-farnesol (a sesquiterpenoid like ABA) which Mansfield's group at Lancaster have reported (Ogunkanmi *et al. Planta* **117**, 293; 1974) to accumulate in drought-stressed sorghum and to be effective at closing stomata.

The question still remains as to whether the postulated role for ABA in promoting stomatal closure is the main role for the apparently excessive quantities of the hormone produced in stress conditions. Many of the known effects of ABA, including reduction in leaf growth or even enhanced leaf senescence (see Milborrow *A. Rev. Pl. Physiol.* **25**, 259; 1974) as well as the reduced proportion of epidermal cells which form stomata and the increased

production of epidermal hairs (Quarrie & Jones *J. exp. Bot.* **28**, 192; 1977), are also well known symptoms of water stress. In the long term, these changes, particularly the reduction in leaf area, may be as important as stomatal closure in reducing water use by plants. Other work (Glinka *Pl. Physiol.* **51**, 217; 1973) indicates that ABA can increase the rate of water uptake by plant roots. Taken together, these results suggest that ABA may be involved in a whole syndrome of responses, all of which may contribute to adaptation to stress environments.

Perhaps many of the other reported effects of ABA, such as those on flowering, may also prove to be adaptations to stress environments. Unfortunately much of the evidence on the developmental effects of ABA is contradictory, so there is a clear need for more careful studies of the effects of applied ABA, taking account of the quantities of the hormone getting into the tissue, its distribution and its ultimate fate.

Research on ABA may have important practical consequences. Following the demonstration that some drought-tolerant species or varieties produce more ABA than sensitive ones (Larqué-Saavedra & Wain *Nature* **251**, 716; 1974; *Ann. appl. biol.* **83**, 291; 1976), several groups around the world are currently screening agricultural crops for ABA production in attempts to breed new varieties capable of high yields in dry regions. Other work concentrates on the use of ABA or its analogues as anti-transpirants to be applied to crops when drought occurs. Much of this work involves the implicit assumption that stomatal closure due to enhanced ABA levels is advantageous in dry situations. Unfortunately the reduction in photosynthesis and harvestable yield which accompanies stomatal closure may outweigh any saving in water, while rapid stomatal closure does not always appear to improve drought tolerance in crops. □

The man-made mouse

from John K. Heath

TERATOCARCINOMAS have been the subject of intensive research effort over the past few years. They are malignant tumours composed of 'undifferentiated' embryonal carcinoma stem cells (EC cells) which can differentiate *in vivo* or *in vitro* into apparently normal differentiated tissue. Since the cells can grow and

John K. Heath is in the Department of Zoology, University of Oxford.

Hamlyn G. Jones is a Lecturer in the Department of Botany, University of Glasgow.

differentiate in culture they could provide a large scale source of material whose behaviour mimics that of the relatively inaccessible mammalian embryo.

The teratocarcinoma story took on a new perspective when it was established by Brinster (*J. exp. Med.* **140**, 1049; 1970), Illmensee and Mintz (*Proc. natn. Acad. Sci. U.S.A.* **72**, 3585; **73**, 549; 1975) and Papaioannou *et al.* (*Nature* **258**, 70; 1975) that when an EC cell from a teratocarcinoma was injected into a normal mouse blastocyst, it could differentiate into fully functional, non-malignant, normal mouse tissue. The possibilities opened up by these observations are enormous. One can suppress the malignancy of an EC cell by placing it in a normal developmental environment. It might be possible to select mutations in culture which are not currently available in normal mouse stocks and examine their effect *in vivo*, thus generating mouse models of human genetic disorders. The ultimate goal would be to achieve a form of genetic engineering at the whole organism level by incorporating genetically manipulated EC cell derivatives into the germ line of a normal mouse and so produce mutant mouse stocks created *in vitro*; the man-made mouse.

Two important advances towards this goal have been achieved. Papaioannou and her colleagues (*Nature*, *op. cit.*; *J. exp. embryol. Morph.* in the press) have shown that EC cells from some cultured teratocarcinoma cell lines can also form functional differentiated tissue in a mouse injected with the cells at the blastocyst stage. This observation has been extended by Dewey *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **74**, 5564; 1977) who have been able to produce a number of mice containing tissues derived from mutant injected cells. The EC cells in question lacked the X-linked enzyme hypoxanthine phosphoribosyl transferase (HPRT). This is a good choice of mutation because it is not available in mouse stocks, but can be readily obtained in cultured cells. HPRT deficiency produces a severe neurological disorder, Lesch-Nyhan syndrome, in humans. A deficiency of this enzyme in humans can also lead to some types of gout. Ten of the mice which have been analysed so far in this study have been shown to contain tissues derived from the donor EC cell. These workers have further been able to demonstrate that the EC cell's derivatives in the normal mouse retain their enzyme-deficient phenotype. None of the chimaeric mice has Lesch-Nyhan symptoms however, despite extensive colonisation of the nervous system by donor tissue in some cases. One further point of interest is that teratocarcinoma-derived blood tissue is rare in these chimaeras, when compared with chimaeras containing tissues from the wild-type version of the same cell line. This could possibly be due to the fact that HPRT⁻ blood cells are at a selective

disadvantage in the normal mouse circulation. This compares with human HPRT⁻/HPRT⁺ female heterozygotes where, due to X-chromosome inactivation, blood cells express either the HPRT⁻ or the HPRT⁺ phenotype, and this has been shown to result in a selective advantage for the HPRT⁺ cells, resulting in an overall HPRT⁺ blood phenotype (Nyhan *et al. Proc. natn. Acad. Sci. U.S.A.* **65**, 214; 1970).

Although the results so far have seemed very promising, a number of important problems have emerged. If a case is to be made for the use of teratocarcinomas as a way of studying normal development, either on their own or in chimaeric combinations with normal mouse embryos, it must be established that the behaviour of an EC cell in a blastocyst parallels that of its normal embryonic equivalent. On the basis of the available evidence, EC cells cannot be said to be the equivalent of the inner cell mass (ICM) cells of the normal embryo. If ICM cells are injected into a mouse blastocyst the resulting chimaeric adult has contributions from the injected cell in nearly all the tissues that have been examined (Ford, Evans & Gardner *J. Embryol. exp. Morph.* **33**, 447; 1975). In addition the chimaeras obtained from ICM injections show a very fine-grained intermingling of donor and host tissue (this is particularly noticeable in the coat, for example). In general, chimaeras from injected EC cells have EC contribution in few tissues, and the EC cells tend to occur in much larger patches compared with ICM cell chimaeras.

Another problem, especially in view of the potential practical applications of these animals in the study of human disease, is that there is only one published report of EC cells differentiating into functional gametes (Mintz & Illmensee *Proc. natn. Acad. Sci. U.S.A.* **72**, 3585; 1975). In this case the EC cells were taken from an *in vivo* ascites teratocarcinoma. No germ-line chimaeras have been reported from blastocysts injected with EC cells from cultured teratocarcinoma cell lines. This is not encouraging, especially when this one animal is set against the total number of blastocysts injected with EC cells. It is not yet clear why most EC cells fail to form functional gametes. One possibility is that most of the teratocarcinoma lines which have been tested are karyotypically abnormal. It is known that most gross karyotypic changes in the normal mouse result in sterility, and it is conceivable that the germ line has some form of 'self defence' mechanism to prevent the inheritance of deleterious chromosomal abnormalities. This problem could be studied with the use of a number of karyotypically normal teratocarcinoma cell lines which have been established.

Another difficulty is that there is no way of controlling the sort of tissues that an

EC cell will form in a normal embryo. This means that comparisons between human disorders and teratocarcinoma chimaeras are very difficult, unless one tissue alone, by chance, happens to be derived in part from the donor EC cell.

The use of teratocarcinoma cell chimaeras as a practical tool in developmental biology and medicine has enormous potential. The results in this area are exciting, but a lot more information is needed on the nature and behaviour of EC cells in the normal mouse embryo before the 'man-made mouse' takes its place as a standard laboratory research tool. □

Beads and skeletons

from Graham Cowling

THE dramatic structural changes that occur in the nucleus of a cell as it prepares to divide, have fascinated biologists for over a century and yet, in terms of molecular interactions, the structure of the eukaryotic chromosome is still far from understood. The revealing discovery of beaded chromatin structure has led to rapid progress in the study of DNA-histone interactions. These advances have, in turn, resulted in various models being proposed to explain how arrays of nucleosomes, the basic building blocks made up of DNA and histones, can be supercoiled to form the higher order structures seen *in vivo* (see for example, Finch & Klug *Proc. natn. Acad. Sci. U.S.A.* **73**, 1897; 1976). Are these aggregates of nucleosomes sufficient to give a complete understanding of the overall organisation of chromatin in chromosomes? It seems unlikely from the recent results of U. K. Laemmli's group which suggest that a network of non-histone proteins is responsible for organising chromatin in metaphase, and possibly interphase, chromosomes.

Laemmli and coworkers (*Cell* **12**, 805; 1977) showed that, after histones and the majority of non-histone proteins had been removed from HeLa metaphase chromosomes by treatment with dextran sulphate and heparin, the chromosomal DNA remains in an organised and reasonably compact structure. These histone-depleted structures sedimented in sucrose gradients as a broad peak (4,000–7,000 S) at a density range distinct from free DNA or intact chromosomes. The isolated complexes, stained with ethidium bromide, appeared under the fluorescent

Graham Cowling is in the Department of Biophysics, King's College, London.

microscope as a central core with the morphology of intact chromosomes, which was surrounded by a halo of DNA. Each chromatid was still paired with its sister chromatid although the central structure was 2–3 times the size of the original chromosome. These histone-depleted structures could be dissociated in 4 M urea, but remained intact when isolated in gradients containing 2 M sodium chloride. Mild treatment with trypsin or chymotrypsin also destroyed their morphology.

Gel electrophoresis of the proteins in the histone-depleted chromosomes revealed the presence of about 30 non-histones, most of which had molecular weights greater than 50,000. No bands with the mobilities of either histones or actin, previously found in nuclei (Douvas *et al. Proc. natn. Acad. Sci. U.S.A.* **72**, 3902; 1975), were seen but one of the three major bands had a molecular weight close to that of the related fibrous protein β -tubulin, but as yet not identified as such.

Electron micrographs of these histone-depleted metaphase chromosomes (Paulson & Laemmli *Cell* **12**, 817; 1977) show in more detail how the core of condensed material retained the original chromosomal morphology and was surrounded by many loops of DNA. In some pictures individual DNA loops, ranging in size from 30–90 kilobases, could be seen leaving the core and returning to a position adjacent to their exit points. No super-coiling of the DNA loops was seen, but as Paulson and Laemmli point out, the preparation of such complexes probably allows nicking of the DNA strands to take place. When histones were removed from the chromosome spreads by prolonged washing with 2 M sodium chloride, reported to remove all histones, similar structures to those prepared by polyanion methods were seen by electron microscopy. It therefore seems unlikely that traces of histones were responsible for retaining the morphology seen.

Concurrent work by Laemmli's group (*Proc. natn. Acad. Sci. U.S.A.* **74**, 4937; 1977) has shown that by treating intact HeLa metaphase chromosomes with micrococcal nuclease, a protein 'scaffold' independent of DNA can be isolated on sucrose gradients. The proteins in these scaffolds were identical to those found in the histone-depleted chromosomes. Even more surprising was that the scaffold's shape resembled that of the original metaphase chromosomes, with pairs of sister chromatids still attached by the edges of the scaffold. This suggests that a network of non-histone proteins rather than DNA governs the overall packaging of the chromosome. Another intriguing aspect of these nuclease-prepared scaffolds is that they contain

small pieces of tightly bound DNA. If scaffold proteins recognise a few specific sequences of DNA, considering the number of loops seen in these structures, any such sequences must be at least called repetitive. Perhaps this represents an exciting new system for the study of DNA-protein recognition mechanisms.

Previous models for chromosome structure have been suggested by electron micrographs of intact chromosomes and recently complemented by the study of the nucleosomal packaging of chromatin. In most part non-histones have been left out of models that use a central core of chromatin to organise the rest of the DNA fibres into loops around its axis (see Stubble-

field & Wray *Chromosoma* **32**, 262; 1971). Laemmli's group has proposed a new model which uses a network of non-histone proteins to both trace out the shape of the chromosome and to organise the surrounding DNA into loops. In histone-depleted chromosomes the masses of free DNA strands are probably the result of unravelling the solenoid or 'superbead' arrays of nucleosomes that surround the scaffold. If this proves to be a general model for metaphase and, possibly, interphase chromosomes further investigation of the scaffold proteins and their changes during the cell cycle may allow a greater understanding of how the cell organises replicated DNA before mitosis. □

Electrical conduction in discontinuous metal films

from Robert M. Hill

DISCONTINUOUS metal films deposited on insulating substrates have been of interest to solid state physicists for many years.

Nucleation theory supports the experimental observation that the initial condensate of a vapour on a clean surface is in the form of small particles and not as a uniform, constant thickness layer. This applies not only to water vapour on a cool substrate but to the deposition of metallic vapours under vacuum conditions. It is only when the average thickness of the deposit is more than some critical thickness that physical continuity is established within the metallic film. The structure of the deposit, in the initial stages of growth, is sensitive to many of the physical parameters of the system. A metal-substrate combination that gives a low surface mobility for the condensate will yield a film formed from small particles closely packed on the surface. Typical dimensions can be as small as 5 nm particle sizes and less than half this figure for the interparticle spacings. These dimensions can be varied by changing the physical conditions during deposition, a higher substrate temperature giving larger particles and wider spacings.

In the classification of solids as metals, insulators and semiconductors the quasi-two dimensional particulate film has been found, experimentally, to bridge the region between insulating behaviour, when the interparticulate spacings are large, and metallic behaviour, when the particles have grown sufficiently to aggregate

and form metallic, percolative, paths. Between these limits a semiconductor-like behaviour is seen but the activation energy of the current is generally very small, and usually less than 0.1 eV.

The transition between the semiconducting and metallic regions can be observed by a change in the sign of the temperature coefficient of resistance. The low temperature coefficient region is of obvious interest as an electronic circuit resistor. Three-dimensional particulate films can be prepared by the co-deposition from vapours of metallic and insulating components, the cermet film, and show properties similar to the two-dimensional structures, with an improved stability. The cermet structure has been used as resistors for almost 20 years.

As with most surface phenomena the properties of a discontinuous metal film are strongly dependent on the ambient conditions. Indeed the films are at best only metastable and can be annealed at temperatures in excess of the deposition temperature with a consequent change in the physical structure and hence in the structure-sensitive properties. This makes physical examination, and the correlation of the structures with other properties, difficult. In a recent review of the field Morris and Coutts (*Thin Solid Films*, **47**, 3; 1977) have critically examined the published information and reach the conclusion that the nature of charge transport in particulate films is, as yet, poorly understood. Much of the information is contradictory and in very few cases has sufficient detail been given to

Robert M. Hill is Reader in Physics at Chelsea College, London.

allow evaluation and comparison of the physical phenomena involved.

Initially the activated behaviour was taken to be evidence of thermal ionisation effects but the magnitudes of the energies involved were found to be roughly inversely dependent on the particle sizes. It is now accepted that coulombic interactions do form the basis of this energy but that the physical size of the particles cannot be neglected. The transport of charge from one particle to another can occur either through the insulating substrate or through the free space. Examination of the energies involved shows that the former is more probable, and the strong dependence of the resistance of the films on the particle spacings indicates that the mechanism is likely to be due to quantum mechanical tunnelling. Supporting evidence is found from the detailed temperature dependence of the low field conductance and from the electric field dependence of the current at high fields. However the magnitudes of the observed currents do not correlate with the observed structure. The obvious explanation of this discrepancy is that the structure is not uniform, and may not even be homogeneous. Electron microscopical investigations show that this is indeed the case, with wide distributions both of particle size and spacing. Only recently have attempts been made to introduce the distributed nature of the parameters into the theoretical models of transport (Abeles *et al. Adv. Phys.* **24**, 407; 1975; Hill & Coutts *Thin Solid Films* **42**, 201; 1977; Leaver *J. Phys. C* **10**, 249; 1977). The problem is undoubtedly difficult for it is necessary to use a percolative approach in which easy transport paths through the material are given a probability weighting dependent on their conductance. But even within these paths the individual particles and gaps are distributed. Recent work has shown that at high temperatures a clear activated region should be observed when transport is between nearest neighbour particles, but at low temperatures where the number of easy paths decreases the activation energy will become temperature dependent as carriers have to be transported to more distant neighbours. This second region of behaviour is similar to the variable range hopping region in amorphous semiconductors (Mott *Festkörperprobleme* **9**, 22; 1969) or in impurity band conduction in heavily doped and compensated semiconductors (Mott & Davis *Electronic Processes in Non-Crystalline Materials*; Clarendon Press, Oxford, 1971) except that the size of the active centres is much larger and hopping can only occur between the supply particle and a limited number of nearer neighbours. Experimental verification of the temperature dependence of the activation energy is not available yet as very few films have been examined at sufficiently low temperatures to observe the full transition in behaviour

(Abeles *et al. op. cit.*).

A range of interesting physical effects has been observed in discontinuous and quasi-continuous metal film structures (Morris & Coutts *op. cit.*). A number of these could form the basis of practical sensors but as electrical charge transport

is central to the understanding of these effects it is essential that our understanding of the process, or processes, involved should be placed on a firm foundation. In their review Morris and Coutts clearly show that this is not the case. □

New light on Phobos, the inner satellite of Mars

from G. Fielder

PHOBOS is a dynamic body with a difference: it is one of the smallest natural satellites in the Solar System, and completes one revolution of Mars every 7.65 hours at a mere 9,000 km from the planet's centre. Recent discoveries about Phobos have opened up exciting prospects for students of planetary science. First, close up views of intact small bodies in the Solar System are few; and, second, exploration of numerous planetary bodies (including natural satellites and asteroids) which offer, collectively, a range of size and a large spread of solar distance is of the highest importance in unravelling the early history and origin of the planetary system.

Two quantities—the radius and mass—are fundamental in planetology. Until the Mariner spacecraft photographed Phobos, in 1969 and (better) in 1971, its

mean radius had to be estimated by assuming an albedo and measuring the amount of sunlight that the satellite scattered back to Earth. And until the Viking Orbiter I was Doppler-tracked, in 1977, to measure its accelerations relative to Phobos, the mass of Phobos could not be computed. Once the mass and radius of a planet are known, the mean density can be calculated: that is important because it is related to the planet's composition. Phobian mass determinations, by two groups of researchers (Tolson *et al. Geophys. Res. Lett.* **4**, 551; 1977; Christensen *et al. Geophys. Res. Lett.* **4**, 555; 1977) who used different methods of processing the same raw data, are therefore of very great interest. The mean value is close to 1.0×10^{16} kg.

But Phobos is not a sphere. There is no reason why it should be since, on such a small body, the particles experience little in the way of mutual gravitational attraction. Photographs (Veverka *et al.*

G. Fielder is at the Lunar and Planetary Unit, University of Lancaster.

Fig. 1 NASA Mariner 9 photo of Phobos showing craters.

Icarus 23, 206; 1974) taken by Mariner 9 showed Phobos (Fig. 1) to be intensely cratered and highly irregular in shape. A few of the craters, such as the 10-km diameter Hall, have widths approaching the mean radius of Phobos itself, and these craters contribute markedly to the overall irregularity. Even a triaxial ellipsoid is not too good a fit to the surface of Phobos, which seems to have semi-axes of about 13.5 (pointing towards Mars), 10.7 and 9.6 km, respectively. The volume of Phobos, corrected for the volume of the craterial depressions (mainly, the largest ones) below the ellipsoid, is about $5 \times 10^{12} \text{ m}^3$; and thus the density turns out to be only $2,000 \text{ kg m}^{-3}$ (2 g cc^{-1}). It is a surprise because it is so small: some scientists view Phobos as a captured asteroid, and the mean density of asteroids is likely to be more nearly $3,500 \text{ kg m}^{-3}$.

What, then, can be deduced about the composition of Phobos? The albedo (Short *Planet. Geol.*, Prentice-Hall, 1975) of Phobos is similar to that of chondritic material, but this has a density that is higher than $2,000 \text{ kg m}^{-3}$. However, the observed low mean density of Phobos can be synthesised using a suitable mixture of carbonaceous chondritic material (which itself contains 20% by weight of water) and voids, or low density materials such as ice. Under the prevailing conditions (the surface temperature of Phobos may be calculated, using an albedo of 0.05, and attains some 230 K or -40°C) ice could exist inside the satellite provided that the interior was not warmer than predicted on the basis of solar heating alone. However, present-day heating of Phobos is not unlikely. Phobos actually resides within the Roche limit for a fluid body which, had it replaced Phobos, would have disintegrated. Phobos remains in one piece because it has more mechanical strength than a fluid. Yet, if the tiny moon were to move only 3,700 km closer to Mars, then even Phobos would probably be torn apart. With the present Mars-Phobos configuration, the materials of Phobos are being subject to stresses of the order of 10^4 N m^{-2} . This kind of stress level is insufficient to fracture solid rocks as we know them on Earth, but new Viking Orbiter photographs (Fig. 2) of Phobos show that its underdense materials have indeed been tidally fractured: the surface displays striking arrays of lineaments (actually approximating to arcs of ellipses), and these lineaments trend in just those directions predicted by the theory of tidal fracturing of a natural satellite which is gravitationally bound to face its primary (Gash, thesis, University of Lancaster, 1973). Even though the orbital eccentricity (0.02) of Phobos leads to rather small changes in the tide-raising force, the components of this force also change in magnitude as a result of the physical libration of Phobos (Duxbury *Icarus* 23, 290; 1974). An

Photo: NASA

Fig. 2 NASA Viking Orbiter photo of Phobos showing crater chains. A series of craters runs horizontally in the picture, which is parallel to the orbit plane of Phobos.

effect of such tidal stressing is to dissipate gravitational energy as heat—in this case, mainly along the fracture lanes. The underdense rock conductivity will be small and it is conceivable that repeated stress changes will lead to the melting of the materials along the fractures. The volatiles will have left through the impact-pulverised upper layers of Phobos and the loosely bonded surface materials will have subsided into the vacant spaces to produce crateriform depressions along the

lengths of the fractures, as observed (Fig. 2). Since these lineaments, or crater chains, seem to dissect all the larger craters on Phobos, it is clear that the fractures have been worked more recently than the most important phase of impact cratering.

Further studies of the new data are likely to throw some light on the orbital evolution of Phobos. Whether or not Phobos is a captured asteroid may then become clearer. □

A hundred years ago

At the meeting of the Linnean Society on Thursday last it was unanimously resolved to send a congratulatory letter to von Siebold on the occasion of his jubilee. This graceful act, however, brings into prominence the neglect of the Society to take any notice of the Linnean centenary, the celebration of which in Sweden, Holland and Germany were recently noticed in our columns. Of course the excuse may be urged with some force that such formalities are foreign to English habits, but perhaps an exception might have been allowed in the case of a Society which bears the name and jealously guards the collections, books and manuscripts of the great naturalist. Perhaps however, another reason may be found in the fact that the constitution of the Society places the initiative in every case in the hands of

officers whose tenure of office is practically indefinite, and who are not very accessible to any impulses of enthusiasm from the general body of the Society even if there were any permissible way by which expression could be given to them. Some disquieting rumours as to the present condition of the Society's business affairs, coupled with its rather troubled history during the past few years, seem to point to the desirability of some changes in its mode of government which would bring the executive into closer relation with the general body of Fellows.

AMONGST the exports of Corsica it is said that there are annually between 350,000 and 400,000 blackbirds (*merles*) which are sent to this continent. They visit Corsica in vast numbers each winter to feed on the berries of the myrtle and arbutus, with which the mountains are covered. In the month of December they become very fat and the flavour and the perfume given to their flesh by their food causes them to be much esteemed by the *gourmets* of Paris. A *pâté de foie de merle* is a great delicacy.

Prevention of spina bifida—the parents' choice

THE problem of prevention and treatment of the congenital malformation spina bifida is in the news again. An all-party motion in the British House of Commons to make prenatal screening for the condition available to all expectant mothers as soon as possible has been signed by over 200 MPs. The screening would involve a blood test, followed, if positive, by amniocentesis (drawing off amniotic fluid) to provide a more sensitive test, followed by offer of abortion if the foetus were found to have spina bifida. Amniocentesis is also of value in the detection of chromosome anomalies such as Down's syndrome and a number of other disorders. Some strong views and some incorrect statistics have been flying around this past month; maybe it will be of value first simply to record some of the basic facts.

The incidence of the neural tube defects, anencephaly and spina bifida varies with race and place. In south-east England the incidences are one in 800 births for anencephaly and one in 600 for spina bifida. But in Wales, Scotland and Ireland the incidence is roughly double this, whereas in African and Mongoloid races the incidence can be less than half that in south-east England. The reasons for this variation are unknown—a different gene pool, soft water or the consumption of blighted potatoes have all been suggested as causes, but so far without confirmation.

If parents have had an affected child the incidence in future siblings is around 4%. There is evidence that both genetic and environmental influences are at work; in most series, consanguinity in the parents is found to be commoner than in the average marriage, monozygotic twins show a higher concordance rate than dizygotic twins and incidence is higher in lower socio-economic groups.

The proposed screening test is an assessment of the level of alpha-fetoprotein in maternal serum. This alpha-immunoglobulin, of uncertain function, is synthesised by some foetal cells and the concentration in foetal serum rises from the 6th to the 14th embryonic week, after which it declines to zero at birth. In neural tube defects the amniotic fluid level is considerably greater than normal and this is reflected in a significant but lesser elevation of the level in the maternal serum. Unfortunately a number of other conditions can give unusually high alpha-fetoprotein levels in the amniotic fluid, such as twinning, foetal death, rhesus immunisation and some other congenital deformities, although it has recently been

shown that study of the cells in the amniotic fluid can discriminate between neural tube defects and other causes of raised alpha-fetoprotein. Other tests such as X-rays, ultrasonics and foetoscopy (direct inspection of the foetus through a fibre-optic instrument) can add to the accuracy of diagnosis, so the likelihood of a false positive result in experienced centres is small. The risk to the mother also seems to be very small, apart from the possibility of rhesus sensitisation. There is a risk estimated at 1–2% to the foetus, mainly of induced abortion, though a recent study showed no significantly increased incidence of abortion.

The outlook for a child born with a neural tube defect varies from certain death in anencephaly to mild weakness of the lower limbs when the defect is minimal. A typical case, if left untreated, will die of infection in due course (though there is occasional survival). With surgery, survival is usual, which is why this was undertaken for most cases from the late 1950s. But there is usually considerable handicap (paralysis of legs, incontinence and deformity—sometimes hydrocephalus and mental deterioration). Most parents who have struggled to look after such a child are prepared to have a prophylactic abortion rather than repeat the experience. The often gloomy outlook has led some doctors to advocate non-treatment of all except mild cases, and Robert Zachary, Professor of Paediatric Surgery at Sheffield University, has recently alleged in the *British Medical Journal* that some are going further than this and practising a mild form of euthanasia. He considers, and an unknown proportion of sufferers from the condition and their parents would agree, that even a restricted life is decidedly better than no life at all.

There thus seems every reason for supporting a much wider availability of screening programmes, not just to restrict the potential for suspicions of euthanasia and not just to reduce unnecessary suffering, but also to give parents a chance to make a calmer and more rational decision at an early stage. Screening is expensive and needs staff training; it will therefore need to be provided on a selective basis, and parents will have to realise that a decision to undergo amniocentesis should not be taken unless they are prepared to go through with an induced abortion if the indications are unfavourable. Association by the Roman Catholic Archbishop of Glasgow of screening programmes with Nazi sterilisation programmes is one way of ensuring that decisions are not taken calmly. □

Benefit-cost analysis and the linear hypothesis

Alvin M. Weinberg, Director of the Institute for Energy Analysis at Oak Ridge, Tennessee warns against a common pitfall of administrators when trying to make cost/benefit analyses of new technologies

ECONOMICS is indeed the dismal science. This was brought home to me as I read the recent report (BEIR-II) of the US National Academy of Sciences, 'Considerations of Health Benefit-Cost Analysis for Activities Involving Ionising Radiation Exposure and Alternatives'. This is a sequel to the 1972 report on Biological Effects of Ionising Radiation (BEIR-I), a study that has been as widely misinterpreted and misused as any the National Academy has issued.

Benefit-cost analysis is simple in principle. In judging whether mass x-ray screening or nuclear power or therapeutic x-rays are worthwhile, one tots up the benefits—early detection of cancers, cheaper electricity, extended life span—and the costs: higher incidence of cancer or genetic disease induced by radiation. If the benefits exceed the costs, the technology is acceptable; if not it is unacceptable—QED.

Unfortunately the measures of cost (human health) and benefit (electricity) are not the same; or much worse, where the exposures are very small, the very question of estimating costs becomes essentially trans-scientific. At least at our present stage of scientific knowledge, and possibly forever, we cannot estimate the carcinogenic or genetic effect of 1 mrem of ionising radiation.

But the economists, not to say administrators, demand a neat cost/benefit calculus. This requires that a common measure, dollars per life, be used for costs and benefits; and this further requires that the vast uncertainties, even uncertainties in principle, as to the effects of low levels of ionising radiation, be obliterated by a stroke of administrative science.

That stroke of administrative scientific ingenuity is the assumption that the linear hypothesis holds down to zero dose (in other words that the biological effect is proportional to dose regardless of the size of dose or the rate of exposure), and the inevitable introduction of the unit 'person-rem'—the product of the number of individuals exposed and the dose in rems to each individual. Having brushed aside the profound illogicalities in the use of the person-rem as an estimator of actual biological damage, the economists and administrators have made the problem tractable: assign so many dollars per person-rem as the cost, so many dollars per life saved, and the cost/benefit calculus is saved.

That nonsense, of course, lies in the use of the person-rem as an estimator of damage. Curiously, the body of the BEIR-I report cautions against so using the person-rem; but the summary, possibly written by someone other than the authors of BEIR-I, in effect uses the person-rem to place bounds on the number of cancers induced by very low level exposure of large populations. BEIR-II takes up where BEIR-I left off, and unfortunately does not re-examine the validity of the original assumption concerning the use of the person-rem as an estimator of damage.

Nevertheless, in a perceptive paragraph in what I thought was the report's best chapter 'Legal and institutional aspects of using benefit-cost analysis to control ionising radiation', one reads "Serious question should be given to the adoption of alternatives to traditional economic benefit-cost analysis for such regulatory decision-making . . . One possible alternative is an appropriately comprehensive cost-effectiveness analysis . . . (that) requires the articulation of objectives, the weighing of the alternative means to achieve these objectives, and the

selection of the least costly approach". Thus, instead of performing magical balancing acts with largely indeterminate costs weighed against incommensurable and equally indeterminate benefits, concede the arbitrary, political nature of the objective at the outset—agree on an appropriately small level of radiation insult that is tolerable, and then go about devising a technology that will meet that objective as cheaply as possible.

A hint as to what the "appropriately small level of insult" should be was given in the 1958 report of the Ad Hoc Committee of the National Committee on Radiation Protection (The Friedell Report *Science*, **131**, 482; 1960). Since the biosphere has evolved in the presence of a natural background of radiation, Friedell asked whether man-made radiation ought to be judged tolerable if it were 'small' compared to this background. This very sensible suggestion was never followed up—instead, we introduced the nonsensical person-rem and strict linear hypothesis, and continued to juggle indeterminate costs and benefits.

To be sure, the definition of 'small' compared to natural background is arbitrary, but at least the arbitrariness is explicit. H. I. Adler, the former director of the Biology Division of Oak Ridge National Laboratory, has suggested (*Health Physics*, in press) that 'small' be taken as the standard deviation of the population-weighted natural background. This amounts, in the United States, to about 20 mrad per year of gamma radiation, and somewhat miraculously, is close both to the EPA emission standard for the nuclear fuel cycle and the NRC standard for emissions from nuclear power plants. The suggestion has been taken up by the American Physical Society's Committee on the Nuclear Fuel Cycle; they point out that if Adler's standard were adopted, then the actual exposures will average to something small compared to the variability in background.

Adler's suggestion amounts to cutting the Gordian knot: proving or disproving the linear hypothesis at very low exposure. The observed incidence of leukemia at Nagasaki persuades me that linearity, with slope determined by the incidence of leukemia at high dose, is inconsistent with the data. Others have looked at various bits of data and insist they see straight lines that go through the origin. But the bald fact is that linearity, upon which the apparatus of cost/benefit analysis for ionising radiation now largely rests, is, for low doses, simply an unproven, probably unprovable hypothesis. I think something like Adler's idea is a far more logical approach to standard setting.

I wax rather vehement because the use of person-rem as an estimator of damage at low dose has badly warped the nuclear debate, and it may have the same effect on the debate over the use of diagnostic x-rays. Thus most of the estimated casualties from a bad nuclear accident are found in the large dispersed population exposed to small doses of radiation. In the original Rasmussen report on reactor safety, credit was therefore given for low doses and dose rates (the strict linear hypothesis was rejected), but the critics insist on using the strict linear hypothesis. BEIR-II, despite the disclaimer previously quoted, recommends that "national policies involving activities such as nuclear power production and medical uses of radiation should be guided to the extent possible by health benefit-cost analysis"; and throughout the report strict linearity is assumed. Why could not this second BEIR report help undo the vast damage caused by the widespread misunderstanding of the first BEIR report, and state, clearly and explicitly, that the use of the person-rem as an estimator of damage is bad science, and this leads to bad policy? I believe BEIR-II must be judged a failure in not having taken the opportunity to correct this unfortunate and widespread misuse of its predecessor report. □

Seafloor spreading in the western Gulf of Aden

R. W. Girdler & P. Styles

School of Physics, The University, Newcastle upon Tyne, UK

Interpretation of a new magnetic survey suggests that the evolution of the Gulf of Aden involved at least two phases of seafloor spreading. A recent phase from about 5 Myr ago to the present is well established and an early phase from about 30–15 Myr ago seems most likely.

A DETAILED geophysical survey was carried out in the western Gulf of Aden in 1975 aboard RRS Shackleton, mainly to discover more about the seafloor spreading history of this region¹⁻⁷. Satellite navigation was used throughout. Here we report the main results of the magnetic survey and conclude that there were at least two spreading phases. We also give a tentative location for the Arabia–Danakil–Somalia triple junction.

The survey

Sixteen profiles were obtained (Fig. 1) about 10 km apart along the direction N32°E. This direction is presumed to be the most likely spreading direction between the Somalia and Arabia plates and is computed from the best fit of the shorelines. All the seismic refraction profiles⁸ show oceanic structures. These are shown in Fig. 1 and will be used in the interpretation.

Two profiles (Fig. 2) illustrate the nature of the anomalies and their relationship to bathymetry. Note that (1) the anomalies over the axial rift and ridge contrast with those over the rest of the Gulf. The former reach more than 2,000 nT, whereas the latter typically reach only 400 nT. (2) Profile *F* shows anomalies symmetrically disposed about the axial rift valley. (3) Profile *B* shows more anomalies to the south of the axial rift than to the north.

Interpretation

Laughton *et al.*⁷ tentatively identified anomaly 5 and suggested continuous spreading over the past 10 Myr. In contrast, it has been difficult to identify anomalies over the Red Sea and establish continuous spreading beyond 3 to 4 Myr ago^{4,5,10,11}. We suggested^{12,13} at least two stages of Red Sea spreading, the first in the Oligocene, the second in the Plio–Pleistocene. As the Gulf of Aden and Red Sea are considered to result from the anticlockwise rotation of Arabia with respect to Nubia and Somalia^{3-5,14-16} and there is no evidence to a first order for shear between Nubia and Somalia, the spreading histories of the Gulf of Aden and Red Sea should be similar. The two interpretations of the magnetic anomalies are, therefore, in conflict.

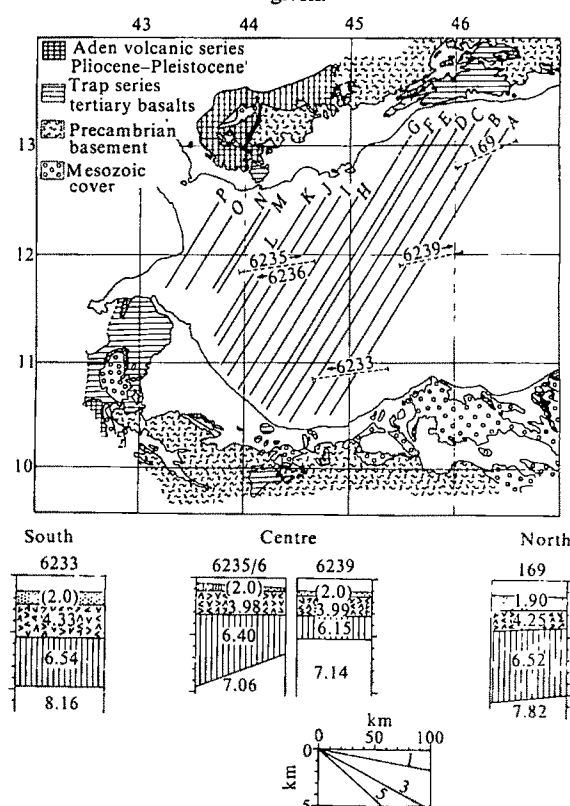

The continuous spreading model of Laughton *et al.*⁷ for the western Gulf of Aden is shown in Fig. 3. It is difficult to correlate the anomalies beyond 3–4 Myr both in number of anomalies and in their amplitudes. We therefore consider an alternative interpretation involving discontinuous rather than continuous spreading.

The correlation of the anomalies back into the Pliocene is good. At the end of the Miocene there was a spectacular change in the conditions of sedimentation in the Red Sea, probably because of some major tectonic event. Possibly, therefore, the most recent phase of spreading started at the time of the

Miocene–Pliocene boundary (about 4.9 Myr ago). Before this there seems to have been a relatively quiet period during which the main trough of the Gulf of Aden accumulated up to 1.5 km of sediment according to the seismic refraction data. For the earlier history, we may look at the geology of neighbouring Somalia and Arabia⁶. The stratigraphy of the northern and southern sides can be closely correlated up to the end of the middle Eocene. After this, sediments are confined to the littoral zones. The main trough could thus have formed between the beginning of the Upper Eocene and the end of the Miocene. The magnetic profiles were therefore compared with synthetic profiles generated for the period from 40–5 Myr.

Figure 4 shows the interpretation for the symmetrical profile *F*. A remarkably good fit can be obtained when the period 30–17 Myr is chosen for the early spreading phase. For the recent phase of spreading, a dipping layer 2 model is used in accordance with the cooling law for new oceanic crust¹⁸. For the older phase the dip is considered negligible, but a much better agreement is obtained if the magnetisation is assumed to reside in layer 3. If layer 2 is included there is too much high

Fig. 1 The locations of the sixteen total intensity magnetic profiles (A–P) in the western Gulf of Aden. The dashed lines with numbers are seismic refraction profiles⁸, the sections for which are also shown (velocities in km s⁻¹). Neighbouring geology is given.

Fig. 2 Two examples of the total intensity magnetic profiles. The regional field removed was the International Geomagnetic Reference Field 1975 (ref. 9) for 1975.25 (the date of the survey) and corrections (upper profiles) for time-variations of the Earth's field were applied using base station records from Djibouti supplemented by magnetograms for H from Addis Ababa. Note the change in character of the anomalies on both sides of the axial rough zone. Vertical exaggeration 23:1.

Fig. 3 The continuous spreading model of Laughton *et al.*⁷ for the western Gulf of Aden together with (a) an observed profile (F) for comparison with (b), the synthetic anomalies, spreading rate 1 cm yr⁻¹ generated using the reversal timescale of ref. 17.

frequency signal on the synthetic profile when the depth constraints of the seismic refraction lines are used. This suggests that the magnetisation of layer 2 decays with age and layer 3 takes over in importance. This has also been noticed by Roeser¹⁹. Alternatively, the model may be too simple; for example, Blakeley²⁰ has proposed an age dependent two layer model for marine magnetic anomalies. This will be discussed further elsewhere.

For profile B (Fig. 5) there are more anomalies to the south of the axial ridge than to the north. When the contrasting amplitudes of the anomalies for the new and old phases of spreading are considered, it seems that the new phase did not start in exactly the same place as the old one stopped. The anomalies can be interpreted in harmony with the interpretation for profile F, provided the former spreading axis is some distance south of the new spreading axis. It seems that the first phase of spreading stopped about 15 Myr ago, that is at the end of the Lower Miocene.

Consideration of all the profiles shows that there are two transform faults between profiles B and F. Interpretation of B and F suggest that spreading to the west of the transform between profiles D and E stopped and started in the same place but spreading to the east of this transform restarted some distance to the north of where it stopped (Fig. 6).

Fig. 4 Seafloor spreading model to explain the magnetic anomalies for profile F. (b) Shows the observed anomalies and (a) the upward continued anomalies (1.83 km). The latter is helpful in identifying various marker features. (c) Shows synthetic anomalies considered to give the best fit. Spreading rates: centre 1 cm yr⁻¹; S limb 1 cm yr⁻¹; N limb 1.13 cm yr⁻¹. These have been computed using the usual simplifying assumption of vertically sided blocks. The seismic refraction profiles (Fig. 1) have been used for the depths and thicknesses of the magnetised layers.

Discussion

The evidence suggests the following history of the Gulf of Aden. First, major movements probably occurred 40 Myr ago; by the end of the Upper Eocene the Gulf of Aden downwarp was in existence and the first major phase of seafloor spreading began 30 Myr ago (beginning of Upper Oligocene). This phase continued until about 15 Myr ago (end of Lower Miocene). There was then a quiet period during which up to 1.5 km of sediment accumulated. At the end of the Miocene, spreading recommenced continuing to the present. We emphasise that this interpretation is the simplest which fits the observations; the possibility of more than two spreading phases cannot be excluded.

The dates for the early stage of seafloor spreading (30–15 Myr) agree well with the dates of basaltic activity in neighbouring regions²¹. They differ from the dates (41–34 Myr) deduced for the Red Sea¹². At that time, the choice of model was constrained by the dates (36.4 ± 2, 36.7 ± 2, 30 Myr) for rocks in

Fig. 5 Interpretation of profile B. Note the smaller amplitude of the observed anomalies on the northern side due to the proximity of a transform fault. (a) Shows the anomalies upward continued to 1.83 km, (b), observed anomalies at sealevel and (c), synthetic anomalies with spreading rate 1 cm yr^{-1} .

Red Sea boreholes²². These are now known to be in error (Nelson, personal communication) and a re-examination of the Red Sea magnetic data (to be published) shows that the magnetic anomalies for the Red Sea can be interpreted in harmony with the seafloor spreading history of the western Gulf of Aden.

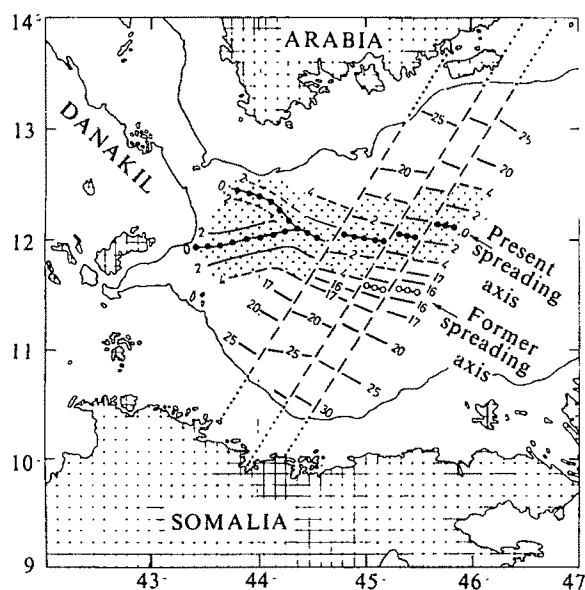

Fig. 6 Isochrons (Myr) deduced from magnetic anomalies for the western Gulf of Aden. The present spreading axis (zero isochron) is shown by a chain of solid circles and the former spreading axis (~ 15 Myr isochron) is shown by a chain of open circles. The three transforms are shown by dotted lines. Land over 3,000 feet (914 m) is cross-hatched.

This has several features in common with an early interpretation by Laughton² who suggested that the development of the Gulf of Aden was a consequence of two distinct phases of continental drift. In phase 1, the continental crust was envisaged to be stretched, thinned and intruded by basaltic dykes. After this there was a period of 'reduced movement' during which the main trough accumulated 0.5 to 1.5 km of sediment. This was followed by phase 2 in which new oceanic crust formed the central rough zone. The new interpretation replaces Laughton's phase 1 by a major period of seafloor spreading over a period of some 15 Myr through the Upper Oligocene and Lower Miocene.

Plate geometry

Figure 6 summarises the magnetic interpretations. From most of the magnetic profiles, it is possible to identify the positions of the 2 and 4 Myr isochrons and these are shown. The region between the 0 and 4 Myr isochrons is stippled, illustrating the minimum extent of the new phase of spreading. The strike of the spreading axis is $N110^\circ E$. Previously⁷, the transforms and offsets had not been recognised and the spreading axis was considered to be continuous with a strike of $N80^\circ E$. The new interpretation is consistent with the ridge-transform pattern further east⁷ and with the direction of separation determined from the fit of the coastlines^{15,16}. In the west, the present spreading axis bifurcates, one branch going towards the Straits of Bab-el-Mandeb and the other towards the Gulf of Tadjura. The bifurcation marks the present location of the triple junction for the Somalia-Arabia-Danakil plates.

For the older spreading phase, the 16, 17, 20 and 25 Myr isochrons are shown. In the extreme south, it is possible to identify tentatively the 30 Myr isochron (close to the Somali shore). This implies that the minimum separation between the Somalia and Arabia plates is 380 km and that a considerable proportion of the Arabia and Somalia coastal plains to the west of $45^\circ E$ must be underlain by 20–30-Myr-old oceanic crust.

In the east of the survey area, the new spreading axis is about 75 km north of the old spreading axis. The transforms associated with the old and new spreading phases are approximately collinear and the isochrons are all approximately parallel. This implies that within the limits of accuracy of navigation, the poles of rotation for the two phases of movement must be very similar and close to the pole of rotation for the total movement, that is $26.5^\circ N$, $21.5^\circ E$ ^{14,16,23}.

We thank Captain P. Warner and the officers and crew of the RRS Shackleton, also Dr J. C. Lepine (Djibouti) and P. Gouin (Addis Ababa) for help with base station magnetometer records; and A. S. Laughton and R. B. Whitmarsh (I.O.S. Wormley) for interest and encouragement. The work was financed by Natural Environment Research Council Grant GR/3/2467.

Structural evidence for gene duplication in the evolution of the acid proteases

X-ray studies of acid proteases indicate a bilobal structure with a well defined active site cleft. An intramolecular two-fold symmetry axis relates two topologically similar domains and the active site residues. A possible mechanism for evolution by gene duplication, divergence and gene fusion is presented.

X-RAY crystallographic studies have shown that proteins are organised into globular domains. Those proteins of molecular weights <25,000 have domains comprising between 100 and 200 amino acid residues. Generally the amino acids in one domain fold individually and are then organised together to give the native tertiary structure¹. Further it is possible that the proteins evolved from smaller functional units by gene fusion; thus lactate, alcohol and glyceraldehyde phosphate dehydrogenases have nucleotide binding domains strongly resembling each other linked to quite different domains which contribute towards substrate specificity^{2,3}. A more primitive nucleotide binding protein may have been a common ancestor³. In other proteins where gene duplication had occurred, it may have been selectively advantageous to follow this by gene fusion leading to a protein with two similar globular domains. We present here evidence for such a mechanism in the evolution of acid proteases leading to a bilobal structure in which an approximate twofold symmetry axis relates two topologically similar domains and the active site aspartate residues.

Acid proteases are so called because they have an optimal catalytic activity at acid pH (for a general review, see ref. 4.) They include mammalian digestive enzymes such as pepsin, chymosin and cathepsin D, microbial proteases such as those produced by *Penicillium janthinellum* (penicillopepsin)^{5,6}, *Rhizopus chinensis* (rhizopuspepsin)⁷, and *Endothia parasitica* (endothiapepsin)^{7,8} and probably certain enzymes involved in mammalian control processes, for example renin, which acts on angiotensinogen.

These acid proteases are characterised by two active site aspartates and most are inhibited by the microbial peptide analogue, pepstatin. They tend to cleave between hydrophobic amino acids but secondary interactions are important in determining specificity⁹. The sequence of porcine pepsin¹⁰ shows that the enzyme has 327 amino acids with the active site aspartates at residues 32 and 215 (see Fig. 1). Pepsin, penicillopepsin⁶ (Fig. 1) and chymosin¹¹ are closely homologous structures and fragments of the sequences of other microbial enzymes¹¹ strongly indicate an homologous series. Medium resolution X-ray analyses of rhizopuspepsin⁷, endothiapepsin^{7,8} and penicillopepsin^{5,6} confirm this structural homology. Preliminary comparisons of the three structures show root mean square deviations between topologically equivalent α carbons^{12,13} (about 200 of each enzyme) of the order of 1.35 Å (data not shown). A stereo drawing of the α -carbon positions of one of these, penicillopepsin, is shown in Fig. 2. The numbering of the

residues is chosen to facilitate comparison with the sequence of pepsin and is given in Fig. 1. The bilobal structure defines an extensive cleft in which the active site residues Asp 32 and Asp 215 are positioned. The two lobes comprise residues -4 to 171, and 177 to 327, connected by a short length of peptide, 172-176. The secondary structure is predominantly β sheet and the general folding is illustrated schematically in Fig. 3. The identity of the residues in the strands is indicated in Fig. 1, and this nomenclature is derived from that described by Hsu *et al.*⁶. It should be noted that Fig. 3 does not indicate the lengths of the β -sheet strands nor of the connecting loops. Furthermore, the extensive sheet is sharply twisted at several points, for example at strands c and m, and this is more clearly illustrated in Fig. 4. The sequences of pepsin and chymosin strongly suggest that they also have similar secondary and tertiary structures.

Internal structural homology

Tang *et al.*¹⁴ noted the remarkable similarity between the residues 30-42 and 213-225 (see Fig. 1) of pepsin. These two stretches of polypeptide include the two active site aspartyl residues at positions 32 and 215. They suggested that this may have been a consequence of gene duplication and fusion, but the pepsin sequence gave no further indications to support this hypothesis. However, consideration of the secondary structure now shows that these residues form similar β structures (c_2 -d and m_2 -n in Fig. 4) and in each case are crossed by a strand (h_1 parallel to c_2 and p_1 parallel to m_2) which gives rise to a psi (ψ) shaped structure. These parallel strands h_1 and p_1 (see Fig. 1) also have some sequence homology and in each case are about 90 residues towards the C terminus from the active site aspartates. In fact, the similarity is considerably more extensive than this as can be seen from Fig. 3. A twofold symmetry axis positioned between antiparallel strands i and q relates the structure in the N-terminal lobe to that in the C-terminal lobe. In particular the active site aspartates, the parallel pairs of strands in the otherwise antiparallel β sheet, the small sections of helix (h_2 and p_2) and the interstrand connectivities in the lobes are equivalent. This striking symmetry is carried over to a large extent into the tertiary structure, as can be seen from Figs 2 and 4. However, the tryptophan residues thought to be equivalent on the basis of the primary structure¹⁴ are not in symmetry related positions.

In order to quantify this symmetry relationship we have compared the two lobes using a least-squares refinement programme for 'topologically equivalent' residues^{12,13}. This evaluates the symmetry in runs of contiguous sequence using a progression rule. In penicillopepsin 61 residues of each lobe are topologically equivalent, and the root mean square deviation for these is 2.01 Å. The two lobes are shown superposed in Fig. 5. The rotation angle is close to that of a twofold but not exact; it is 174.6° and there is a translation of 1.0 Å along this rotation axis relating the two lobes.

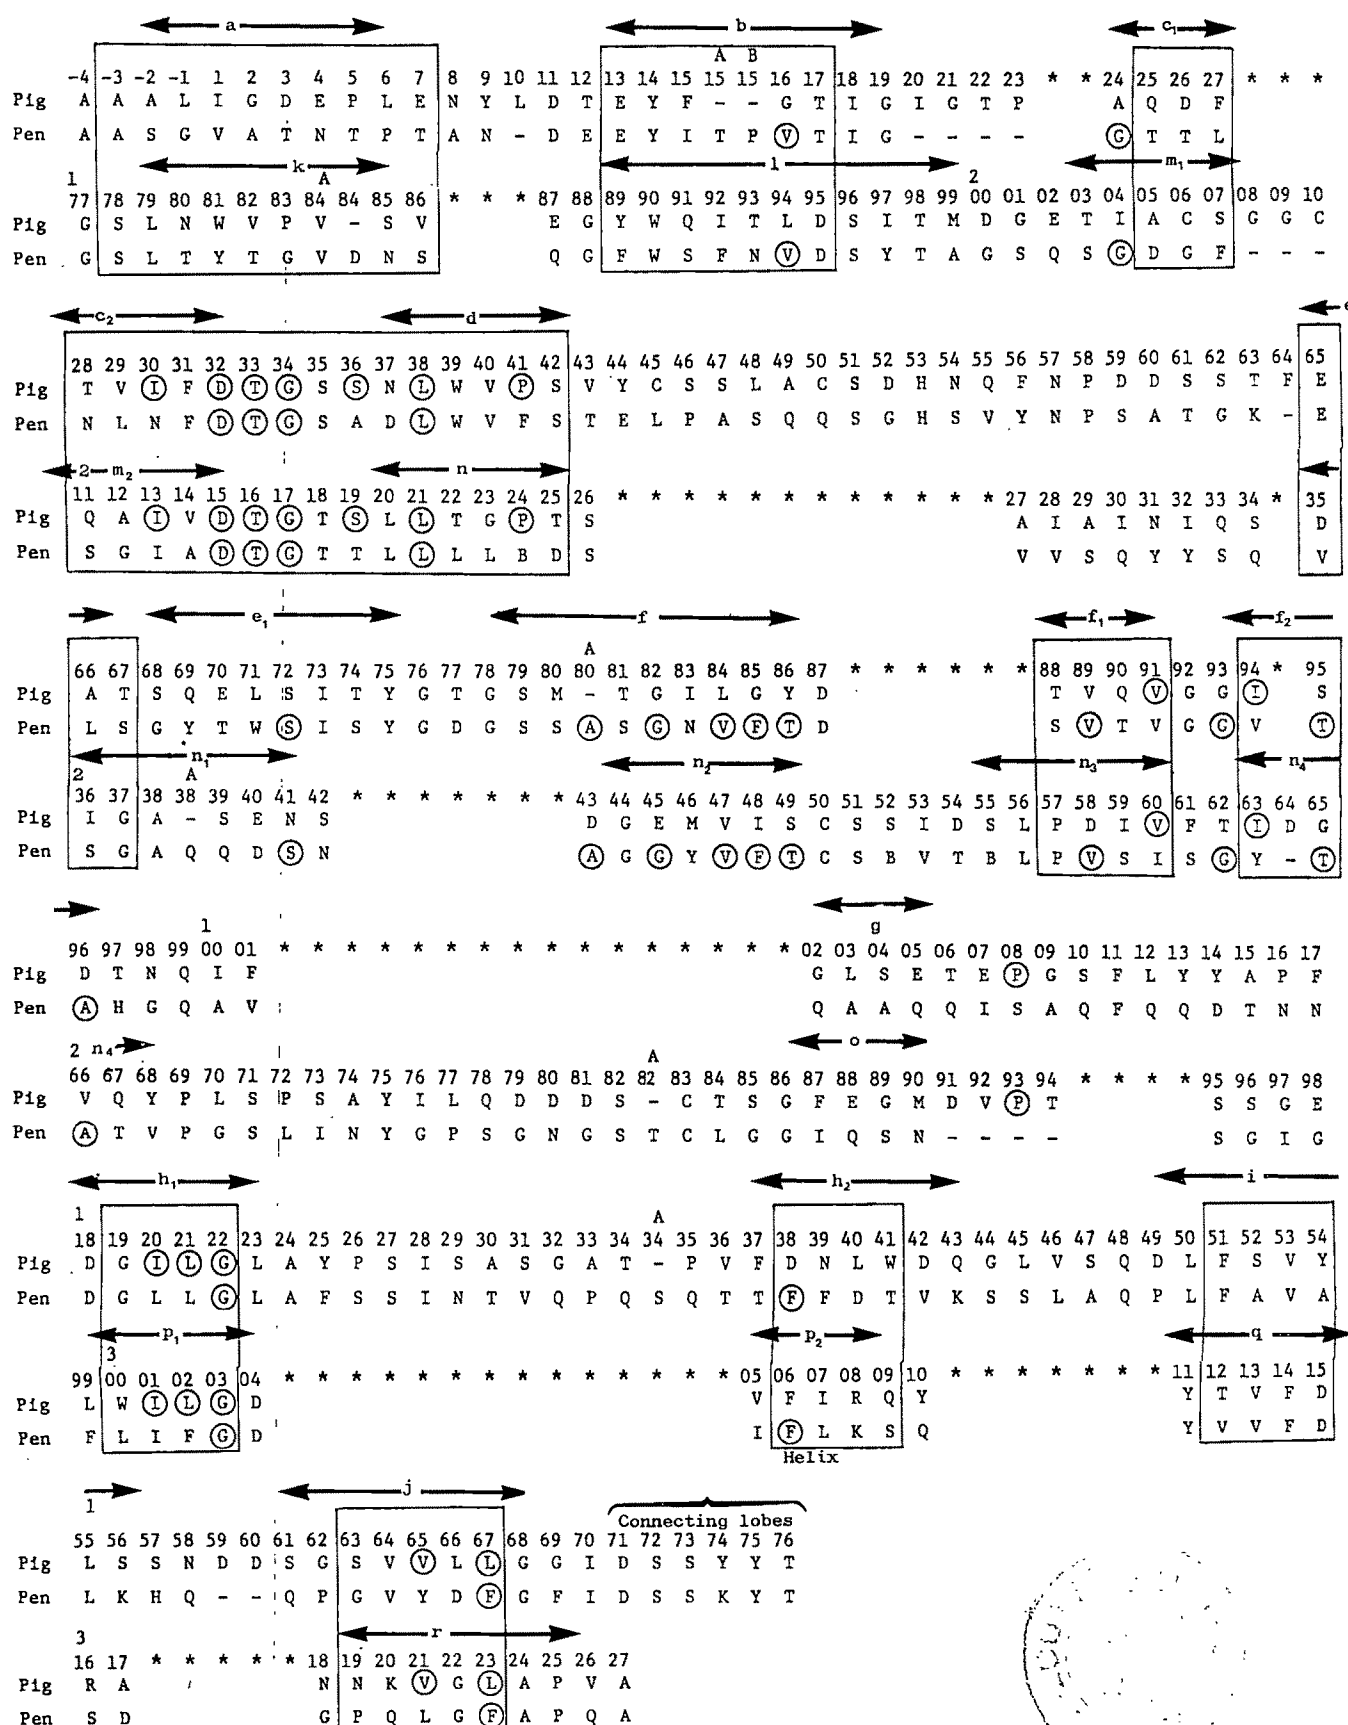

Fig. 1 The sequences of the acid proteases, porcine pepsin and penicillopepsin, aligned to maximise the internal structural homology. Residues in boxes are 'topologically equivalent residues'. Circles indicate residues which are identical in the two lobes. Asterisks identify positions where there is no topologically equivalent residue. The residue numbering is that of porcine pepsin and the strands are lettered to facilitate discussion in the text and identification in the schematic Figs 3 and 4.

Fig. 2 Stereo drawing of the α -carbon positions of the acid protease, penicillopepsin. The residue numbering given in Fig. 1 is designed to facilitate comparison with the homologous pepsin structure. Structures of the acid proteases, endotheiapepsin and rhizopuspepsin, are very closely related. The enzyme is viewed along the approximate twofold symmetry axis relating the two lobes of the enzyme as described in the text.

Fig. 3 A schematic drawing of the secondary structure found in the acid proteases. The strand labels are defined in Fig. 1. Strands a-j are in the N-terminal of Fig. 2 and related by an approximate twofold symmetry axis to the strand k-r in the C-terminal lobe. There are rather large angles between some strands such as d and g, n and o; strands c and m bend in the centre as shown in Fig. 4.

Fig. 4 A schematic drawing of the tertiary structure of the acid protease, endotheiapepsin, viewed along the twofold axis. The strand labels are defined in Fig. 1.

The 61 topologically equivalent residues are indicated in Fig. 1 by inclusion in boxes. Assuming porcine pepsin is homologous there are 58 such residues in this enzyme. The sequences are aligned to optimise the topological equivalence. This inevitably leads to gaps which are indicated by asterisks in Fig. 1. These correspond to loops of polypeptide which are present in one lobe but absent in the other.

Several of the differences between the lobes correspond to extensions or deletions of β loops connecting two adjacent antiparallel strands of the β sheet. Thus the loop k-l is a few residues shorter than a-b, and b-c₁ is much less extended than l-m₁, and q-r is less extended than i-j. A more striking example is the loop n₁-n₂ which is seven residues shorter than e₁-f. In other places, for example d-e compared to n-n₁, the chain folds across several strands of sheet and a larger length of less tightly folded polypeptide is inserted on one side (residues 43-55 between d and e). Similar additions and deletions occur in the strands connecting h₁-h₂-i and p₁-p₂-q; in this example rather long stretches of polypeptide are inserted between h₁-h₂ and h₂-i compared to p₁-p₂ and p₂-q, but the two helices h₂ and p₂ nevertheless partially overlap (see Fig. 1).

The insertions which give rise to difference between the lobes are on the surface or available to the surface of the enzyme and do not interfere with the general tertiary fold. Indeed, deletions or additions occur often between penicillopepsin and pepsin in positions which are topologically inequivalent between the lobes; for example the deletion of residues 20-23 (between b and c₁) of pepsin in penicillopepsin. Further, the loop e₁-f which differs from n₁-n₂, is completely on the surface, and these residues in penicillopepsin differ from the equivalent loop in endotheiapepsin and rhizopuspepsin.

Evolution by gene duplication

The two lobes of the acid proteases thus have approximately 35% of the residues in topologically equivalent positions. These results are similar to those observed for the bacterial and pancreatic serine proteases with an important difference. It was first pointed out by Shotton and Watson¹⁵ that in elastase the two domains have a similar fold, but the twofold relationship is such that the polypeptide chain of the C-terminal domain has the opposite polarity to that in the N-terminal domain. This has subsequently been observed in the bacterial serine proteases where the twofold relationship between domains is more exact^{16,17}. It can be concluded, therefore, that the similarity of conformation in the two domains of the serine proteases is a

result of specific structural requirements rather than a gene duplication event. This may not be the case for the acid proteases for the twofold relationship between the two lobes leaves the chains with the same polarity. However, the lack of sequence homology is striking. Of the 61 topologically equivalent residues there are only 10 identical residues in penicillopepsin and 14 in porcine pepsin. This may be taken to support the view that the acid protease fold has evolved convergently in the two lobes. Alternatively it indicates that the secondary and tertiary structure is conserved in evolution to a greater extent than the primary structure of a protein.

The acid protease fold described here involves the stacking of β sheets together. If divergent evolution has occurred in the two lobes, complementary changes must have occurred in residues

fusion would be selectively advantageous in assuring the correct association of dissimilar subunits. These steps are shown schematically in Fig. 6. In fact the connecting peptide between subunits is in a surface position and probably could be cleaved without denaturing the enzyme. Indeed, Rajagopalan *et al.*²⁵ have shown that porcine pepsin carrying various cleavage sites is still catalytically active and it is fascinating that this may be a reflection of the evolution of the enzyme from two smaller globular proteins.

This outline for the evolution of the acid protease structure is supported by analogous observations made in several other protein structures. Crystallographic studies of the ferredoxin from *Clostridium pasteurianum* show that the iron and labile sulphur atoms are arranged in two clusters each of which is

Fig. 5 A stereo drawing of the α carbons of the N-terminal lobe (open virtual bonds) superposed on the α carbons of the C-terminal lobe (closed virtual bonds) after rotation by the approximate twofold symmetry operation described in the text.

contributing to the core between these sheets, possibly in a protein formed by gene duplication and not under selective pressure¹⁸. Although changes may occur in one of a complementary pair of amino acid side groups which give a poorly folded or unfoldable structure, the same fold may later be optimised by further changes.

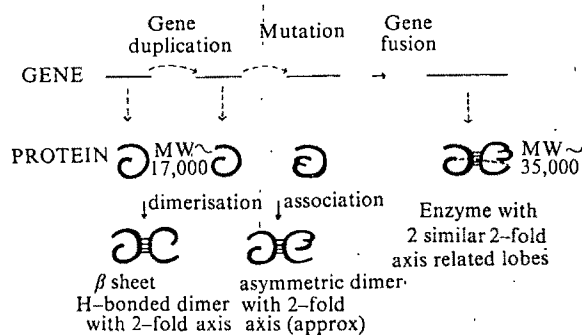

Thus it seems possible that acid proteases evolved by gene duplication of an ancestral protein of about 150 residues having a fold similar to that of one lobe of pepsin. Even before duplication a dimer of two identical subunits may have existed. The extensive hydrophobic interactions and the antiparallel pleated sheet between the two lobes of the acid protease (strands q and i) are reminiscent of similar quaternary interactions involving antiparallel sheet in insulin¹⁹ and liver alcohol dehydrogenase dimers²⁰, and in concanavalin^{21,22} and prealbumin tetramers²³. After the gene duplication event the two subunits evolved divergently so that the carboxyl groups of the two aspartyl residues developed different *pK*s and a mechanism of hydrolytic cleavage, as described recently²⁴. Finally, gene

enclosed by a similar folding of the polypeptide chain²⁶. In the bacterial ferredoxins, however, the sequences of the two similar folding units are more homologous than that which we report here for the acid protease folding domains. Rhodanese, the sulphur-transferring enzyme from bovine liver, consists of a single polypeptide chain which folds into two nearly identical domains, but only 14 of the 109 topologically equivalent residue pairs are identical in sequence²⁷. This latter figure is equivalent to the lack of homology between the two domains of the acid proteases, and indicates that a homologous amino acid sequence is not a necessary condition for similar tertiary structures. This phenomenon of folding domains that are similar in conformation but with widely differing primary structure would seem to be a rather common one.

We thank Mrs E. Wood for drawing Figs 3 and 4. J.A.J. and T.L.B. thank the SRC for support.

Received 3 October; accepted 16 December 1977.

Purification of mouse interferon by sequential affinity chromatography on poly(U)- and antibody-agarose columns

Jaqueline De Maeyer-Guignard

Institut du Radium, Université de Paris-Sud,

M. G. Tovey and I. Gresser

Institut de Recherches Scientifiques sur le Cancer, 94800 Villejuif, France

E. De Maeyer

Institut du Radium, Bâtiment 110, Université de Paris-Sud, Orsay 91405, France

Mouse interferon has been purified to homogeneity by two-step affinity chromatography. Two polypeptide bands were obtained on sodium dodecyl sulphate-polyacrylamide gel electrophoresis migrating at molecular weights 35,000 and 22,000, both having antiviral activity. The 35,000 but not the 22,000 band, also stained with periodic acid-Schiff. The specific activity was 8×10^6 of our laboratory units, corresponding to 2.4×10^6 NIH reference units.

COMPLETE purification of interferon will make it possible to determine whether the varied biological effects attributable to interferon preparations are due to the interferon itself. Furthermore, analysis of the structure of interferon may reveal its active site(s) and eventually lead to its synthesis *in vitro*; also by labelling the molecule, it will be possible to investigate the initial interaction of interferon with the cell. Although techniques have been developed for the large-scale production¹ and purification of mouse interferon by affinity chromatography²⁻⁷, total purification has not been achieved. Knight, using gel filtration and ion-exchange chromatography, reported that purified mouse L cell interferon still had "10 to 11 polypeptide" bands after sodium dodecyl sulphate polyacrylamide gel electrophoresis (SDS-PAGE)⁸. We now report the purification of mouse C-243 cell interferon with a high final recovery of

biologically active and pure material by SDS-PAGE.

Interferon titrations were performed using either a microtitre assay in L cells or a plaque reduction assay in 5-d-old secondary cultures of mouse embryo fibroblasts (MEF), with vesicular stomatitis virus (Indiana strain) as challenge virus. One microtitre unit per 0.2 ml corresponds to 10 MEF units per ml. All titres are expressed in MEF units. One MEF unit equals 0.3 NIH reference units.

Electrophoresis on acrylamide slab gels

Either plain 13% or 15% gels or exponential 10–20% gradient gels were prepared in slabs 0.075 cm thick, 11 cm long and 16 cm wide. A 5% stacking gel 1 cm high was prepared with sample wells of either 0.025 or 0.05 ml. The discontinuous buffer system using SDS has been described by Laemmli⁹. Before electrophoresis, samples were dialysed for 18 h at room temperature against 0.125 M Tris-HCl, pH 6.8, 1% SDS and 10% glycerol. β -Mercaptoethanol (1%) was added sometimes. After dialysis, some samples were concentrated 10- or 15-fold with a Minicon-B concentrator, with 15,000 molecular weight cutoff (Amicon, Lexington). Gels were run for 5–7 h depending on the concentration of the acrylamide at a constant current of 10 mA per gel, and 20 μ l of sample was usually applied per slot. After electrophoresis, gels were stained for 15 min in a solution of 0.1% Coomassie brilliant blue in a mixture

Fig. 1 Electrophoretic profile of interferon activity recovered from 10–20% acrylamide gradient gels. The starting material for (a) was 20 μ l crude interferon, concentrated tenfold, and containing 2.6×10^6 U; for (b) it was 20 μ l of interferon purified on an immunosorbent column (Fig. 2) and containing 3×10^6 U; and (c) it was 20 μ l of interferon purified on poly (U)-Sepharose and containing 5×10^6 U. Crude interferon was used as starting material both for the chromatography on anti-interferon globulin bound to Affigel-10 and on poly (U)-Sepharose. ---●---, Migration of molecular weight markers. For the elution of interferon from acrylamide gels, they were fractionated into 2-mm slices. Optimal results were obtained consistently when slices were eluted for at least 18 h at 4°C in electrode buffer (0.025 M Tris, 0.2 M glycine and 0.1% SDS) using 0.2 ml per slice. Total recovery of interferon activity was obtained in these conditions. The form of the gel changed as a result of staining and drying and it was not possible to correlate precisely the antiviral activity eluted from the slices obtained from a fresh gel with the stained bands of a dried preparation. This difficulty was circumvented as follows. Two aliquots of the same gel were deposited into each of two slots, with an empty slot in between. At the end of the run, before staining, the gel was cut longitudinally along a line centred on the empty slot, and care was taken not to displace the two parts of the gel with respect to each other. Another longitudinal cut, parallel to the first, was made at the other side of the sample run to be eluted; this gave a slice 1 cm wide. The latter was cut transversely every 2 mm, and each cut was prolonged a few millimetres every 2 mm, and each cut was prolonged a few millimetres into the gel reserved for staining. It was thus possible, after staining and drying, to correlate the antiviral activity of each fraction with protein bands by counting the notches.

of 50% methanol, 10% acetic acid and 40% distilled water; they were destained overnight in a solution of 7% acetic acid and 5% methanol in distilled water and then dried.

Crude interferon preparation

Mouse interferon was prepared from suspension cultures of Swiss mouse C-243 cells induced with Newcastle disease virus (NDV) and titred 1.3×10^8 U ml⁻¹; its protein content was 0.1 mg ml⁻¹ and its specific activity was 1.3×10^7 U per mg of protein.

The crude starting interferon preparation, when electrophoresed in the presence of SDS in non-reducing conditions, contained two peaks of activity, one migrating at 35,000 molecular weight (MW), representing about 80% of total activity, the other migrating at 22,000 MW and representing about 15% of the activity (Fig. 1a). These findings are in good agreement with those reported by Stewart *et al.* for NDV-induced L-929¹⁰ and C-243 cell¹¹ interferons (for the latter interferon they reported a molecular weight of 38,000 rather than 35,000). Likewise, we have found that treatment of interferon in reducing conditions (buffer supplemented with 1% β -mercaptoethanol) resulted in a 90% or more reduction of the antiviral activity of the 22,000 MW peak, whereas the activity of the 35,000 MW fraction was unaffected.

Interferon obtained from poly(U)-agarose and antibody-agarose

Affinity chromatography of C-243 cell interferon on poly(U)-Sephacrose 4B (Pharmacia) has been described before¹². Briefly, an interferon sample, predialysed for 24 h in 10 mM Tris-HCl, pH 7.5, is applied to the gel and desorption is obtained by adding 1 M NaCl to the Tris buffer. By this simple procedure,

we obtained mouse interferon preparations with specific activities of up to 10^8 U per mg of protein. Furthermore, recovery was total with both peaks of activity (35,000 and

Fig. 2 Affinity chromatography of C-243 cell interferon on an anti-interferon globulin Affigel column. Anti-interferon serum was prepared and partially purified as before¹³. The partially purified anti-mouse interferon serum used had a neutralising titre of 2.4×10^6 U when assayed against 16 U of interferon. One ml of serum neutralised 6.4×10^8 interferon reference units. Immunoglobulins were precipitated with 2.1 M ammonium sulphate, processed as before² and coupled to an agarose matrix with a spacer arm, Affigel-10 (Bio-Rad). The globulin fraction obtained from 15 ml of the anti-interferon serum was fixed to 1 g of Affigel-10. A crude interferon preparation (240 ml) containing a total of 3.12×10^8 U was applied to the column. The loaded column was washed with 10 bed volumes of phosphate-buffered saline (60 ml) and desorbed with citrate buffer (1 M NaCl, 0.1 M Na citrate, pH 2.2); 3.0-ml fractions were collected. Total recovery was 3.7×10^8 U, that is 119% of input, and the specific activity of the pooled peak fractions was 2×10^8 U per mg of protein. An aliquot of the peak fraction with the highest titre was dialysed against sample buffer, concentrated 10-fold, and analysed on a 15% acrylamide gel (Fig. 3a, channel 3). Protein content was determined by the fluorometric assay described by Boehlen *et al.*¹⁴. In some instances the protein content was estimated after PAGE from the intensity of the staining of the bands with Coomassie brilliant blue. This was done by comparison with bands obtained after electrophoresis of known amounts of bovine serum albumin and ovalbumin. — — —, Absorbance at 260 nm; —●—, interferon titre.

Table 1 Summary of two-step purification procedure

	Volume (ml)	Titre (U ml ⁻¹)	Total U	Specific activity (U per mg of protein)
Starting material	200	1.3×10^6	2.6×10^8	1.3×10^7
Peak fractions from poly(U)-Sephacrose column	(1) 5 (2) 5 (3) 5 (4) 5	1.0×10^7 4.0×10^7 1.0×10^7 1.3×10^6	3.0×10^8 (115% of starting material)	1.2×10^8 (pool 1-4)
Peak fractions from solid phase immuno-adsorbent column	(1) 2.5 (2) 2.5 (3) 2.5 (4) 2.5 (5) 2.5	4.0×10^7 4.0×10^7 2.0×10^7 2.5×10^8 1.3×10^6	1.0×10^8 * (38% of starting material) 1.5×10^8 † (52% of starting material)	ND 8.0×10^8 8.0×10^8 ND ND

Crude starting material (200 ml) was dialysed overnight against 10 mM Tris-HCl buffer, pH 7.5, and was applied to a poly(U)-Sephacrose column (total bed volume 10 ml). The column was then rinsed with 10 bed volumes of Tris-HCl and desorption was carried out by adding 1 M NaCl to the buffer. The four 5-ml desorption fractions were pooled and diluted fivefold in 10 mM Tris to decrease the molarity of the preparation to be applied to the solid phase immuno-adsorbent. Thus 100 ml was applied to the anti-interferon globulin-agarose column (bed volume 4 ml). After absorption, the column was rinsed with 10 bed volumes of phosphate-buffered saline and desorption was carried out in 0.1 M citrate buffer, pH 2.2, supplemented with 1 M NaCl. Fractions (2.5 ml) were collected and the bulk of interferon activity was recovered in fractions 1-3. These fractions were concentrated 15-fold and analysed electrophoretically. Fraction 1 still contained some contaminating polypeptide bands in the low molecular weight range (<20,000) but fractions 2 and 3 showed only the two bands corresponding to interferon activity.

*This material was still slightly contaminated with other polypeptides.

†This material was electrophoretically pure. (Fig. 3a, channel 4.)

22,000 MW) being recovered (Fig. 1c). As Fig. 3a shows (channel 2), the two bands corresponding to interferon can be seen after staining. In addition to the two polypeptide bands corresponding to interferon, there are many other contaminating polypeptides.

Purification of C-243 cell interferon on antibodies covalently bound to agarose through a spacer arm (Affigel-10) is described in Fig. 2 and the product is illustrated in Fig. 3. Interferon recovery was complete and, on electrophoresis a migration pattern comparable with that of the starting material was obtained (Fig. 1b). Again, although an extensive degree of purification was achieved (230-fold to yield a product with specific activity about 3×10^8 U per mg of protein), contaminating polypeptides were still present in the preparation (Fig. 3a, channel 3). Because the polypeptide contaminants retained by the affinity chromatography of the crude interferon preparation on poly(U)-agarose were different from those retained by the antibody-agarose column, we decided to combine the two techniques.

Sequential affinity chromatography

The crude interferon preparation was first purified on poly (U)-Sephacrose and the product was applied to an anti-interferon globulin column. Experimental details and results are given in Table 1 and illustrated in Fig. 3a, channel 4. After concentration and electrophoresis of an aliquot of fractions 2 or 3,

Fig. 3 SDS-PAGE in a 15% gel of interferon (IF) preparations of different degrees of purity. *a*, Input per channel was 20 μ l in each case. Channel 1, molecular weight markers; channel 2, after purification on poly (U)-agarose; input was 1×10^7 U; channel 3, after purification on antibody-agarose; input was 1.3×10^7 U; channel 4, after combination of the two methods; input was 1.2×10^7 U. *b*, Migration of interferon after boiling in denaturing conditions. Channel 1, molecular weight markers; channel 2, purified preparation containing 6×10^6 U in 10 μ l. Molecular weight markers from top to bottom: bovine serum albumin, ovalbumin, chymotrypsinogen and cytochrome *c*.

only two protein bands migrating at 35,000 and 22,000 MW were observed. When slices of the uncoloured gel corresponding to these two bands were eluted for biological activity, there was excellent correlation between interferon activity and the stained bands (Fig. 4). As Fig. 3a, channel 4, and Fig. 3b, channel 2 show, this preparation can be considered pure because no other bands were detected (the limits of detection with the method in our hands was 0.07 μ g of either bovine serum albumin (BSA) or ovalbumin). In one experiment we put 2.5 times as much material on the gel as was used for Fig. 3a, channel 4, by starting the electrophoresis with 20 μ l and refeeding twice, each time with 15 μ l (using a higher stacking gel). The two interferon bands were more diffuse than those obtained in normal conditions, which was expected in view of the way the material was placed on the gel, but again no contaminating bands were observed. In addition to electrophoresis on a 15% gel, the pure material was run in a 13% gel and in a 10–20% gradient gel, and each time antiviral activity was present in gel slices corresponding to the two stained bands.

For the interferon band to be quite distinct, it was necessary to put a minimum of 20 μ l per slot of a preparation of titre 3×10^8 U ml⁻¹ (that is 6×10^6 U per slot). In these conditions the intensity of the stain with Coomassie brilliant blue corresponded roughly to 0.75 μ g of protein, for the two bands combined, using BSA as standard. This represents 37.5 μ g of

interferon per ml for a preparation of titre 3×10^8 U ml⁻¹, which means that the specific activity was 8×10^6 U per mg of protein. The 35,000 MW band was rather broad, but such dispersion is not unusual for glycoproteins and there is evidence that at least some interferons are glycoproteins^{15,16}.

To determine whether the purified product contained sugar we stained the gel with periodic acid-Schiff (PAS) after PAGE in a 15% gel. We used 15 μ l of the same concentrated preparation used to stain the polypeptide bands with Coomassie brilliant blue as shown in Fig. 3. While the 35,000 band stained almost as intensely with Schiff's reagent as with Coomassie brilliant blue, the 22,000 band hardly stained at all. No other bands were visible. Thus there was more sugar present in the 35,000 MW fraction than in the 22,000 MW fraction.

To exclude the possibility that the 35,000 MW component was a dimer of the 22,000 MW component, an aliquot of the preparation that had been electrophoresed for activity (Fig. 3a, channel 4 and Fig. 4) was supplemented with 1% β -mercaptoethanol and boiled for 1.5 min before electrophoresis. This treatment did not affect migration of either band (Fig. 3b, channel 2).

Correlation between antiviral and cell multiplication inhibitory activities

Individual fractions, after SDS-PAGE, of the 35,000 band purified interferon were tested for antiviral activity on L cells

Fig. 4 Profile of interferon activity recovered after electrophoresis of the pure preparation. An aliquot of fraction 2 obtained after desorption of the anti-interferon globulin-agarose column (Table 1) was dialysed and concentrated 15-fold before electrophoresis (see legend to Fig. 1). A 20- μ l sample was electrophoresed in a 15% acrylamide gel for staining (Fig. 3), and in an adjacent channel another 20- μ l sample was electrophoresed to recover activity. The theoretical input was 1.2×10^7 U per channel. The total recovery of interferon activity after electrophoresis was 1.9×10^7 U (158% of input); 79% of this activity was recovered from the three slices corresponding to the 6-mm area of the stained 35,000 molecular weight band, and 19% from the two slices corresponding to the 4-mm area of the 22,000 band. The remaining 6% was recovered from the area in between and adjacent to the bands. Comparable results were obtained when the electrophoresis was carried out either in a 13% or in a 10–20% acrylamide gradient gel. —●—, Migration of molecular weight markers.

and cell multiplication inhibitory activity on murine leukaemia L1210 cells, as described before^{11,17}. As Fig. 5 shows, there was an excellent quantitative correlation between the two activities.

We conclude therefore that mouse interferon can be purified considerably by affinity chromatography using poly (U)-Sephacrose¹² or anti-interferon globulin columns². Combining both techniques, we obtained interferon that seemed pure after SDS-PAGE—we consistently obtained only two bands after staining either with Coomassie brilliant blue or PAS.

The fact that both the 35,000 and 22,000 MW components were purified together on the antibody-agarose column does not imply that they are antigenically identical, for immunisation had been carried out with the crude starting material containing both components. They were also purified together on the poly (U)-agarose column, indicating that each of them has a polynucleotide attachment site¹². By comparing the intensity of coloration of each band with a known BSA standard, we estimate that this interferon has a specific activity of at least 8×10^9 U (2.4×10^9 NIH reference units).

Our results differ in several important respects from those obtained by Knight who reported the purification of mouse interferon from L cells induced with MM virus⁸. His purified interferon preparation contained 10–11 different bands, whereas ours contained only two bands when stained with

Our results suggest, in agreement with Knight's findings⁸, that the 35,000 MW component is not a dimer of the 22,000 MW component because the electrophoretic profile did not change after boiling in denaturing conditions. Possibly the two components are different gene products, and there are some data to suggest this may be so for human leukocyte interferon¹⁸. If the two polypeptides were different gene products, the proportion in which they are produced could well depend on the cell and also on the inducer used. It is also possible that the 22,000 MW component corresponds to the polypeptide part of the 35,000 MW component from which the sugar moiety has been removed. In addition, the low biological activity found between the two stained bands may correspond to the interferon peptide with intermediate degrees of glycosylation.

We have presented evidence that interferon can inhibit cell multiplication^{11,17} and have suggested that interferon has an important role in the regulation of cell division and function¹⁹. Although this has been a subject of some controversy (see ref. 11 for references), the results presented here show that there is excellent correlation between the antiviral and cell multiplication inhibitory activities of our pure mouse interferon. Knight⁸ has reported that purified human fibroblast interferon also inhibited the multiplication of human fibroblasts. Now that mouse and human interferon have been purified it will be important to determine whether other biological effects (see refs in ref. 19) observed with crude or semipurified preparations are due to interferon.

The specific activity of purified mouse C-243 cell interferon is 2.4×10^9 NIH reference units per mg of protein, which means that for a molecular weight of 22,000 interferon is active at a concentration of 1.9×10^{-15} molar. Interferon would thus seem to be one of the most biologically active of all polypeptides.

We thank A. Cachard, M. C. Hoyez, P. Nicolas, M. T. Bandu, J. Begon-Lours and J. Buwyid for technical assistance, and Drs D. Brouty-Boyé, D. Buffe, E. Knight, E. Mogensen, R. Monier, F. Pochon, C. Rimbaud, M. N. Thang and J. P. Waller for discussions and help. Some of the interferon was from Laboratoire Roger Bellon. This study was aided by La Fondation pour la Recherche Médicale Française, the Délégation Générale à la Recherche Scientifique et Technique (contracts 76.7.1481 and 75.71670), Direction des Recherches Etudes Techniques, Direction Ministérielle pour l'Armement (contract 76/342) and CNRS (grants ATP 3174 and AI 00031858). We dedicate this article to the memory of our friend and colleague Ikuya Nagata.

Fig. 5 Anticellular activity after elution of pure interferon from a 13% gel (with 1% β -mercaptoethanol). *a*, Antiviral activity as assayed on mouse L cells challenged with vesicular stomatitis virus. *b*, Cell multiplication inhibitory activity as assayed on mouse leukaemia L1210 cells^{11,17}. All gel eluates were incubated with 6×10^4 L1210 cells per ml in 2 ml of RPMI 1640 medium containing 10% foetal calf serum, and cell multiplication was determined after 3 d of incubation by counting viable cells in a haemocytometer and using the Trypan blue dye exclusion test. All eluates were tested at a 1:10 dilution. All points are averages of duplicate determinations. \blacktriangle , Migration of molecular weight markers: ovalbumin, chymotrypsinogen and cytochrome c.

Coomassie brilliant blue or PAS, and the interferon peaks were more pronounced and with much less dispersion of biological activity than in his study. Our 22,000 MW peak represented only 15% of total activity and stained less with PAS than did the 35,000 MW peak, in contrast to Knight's results in which the low molecular weight peak was the major component and also stained more intensely with PAS. The possibility that we have selected interferon molecules at both extremes of the molecular weight range during purification, and lost the intermediate ones, can be ruled out, because recovery from chromatography on both antibody and poly (U) was close to 100%, and in addition we showed that the interferon activity of the crude starting material had an electrophoretic profile identical to that of the purified product. These differences between Knight's results⁸ and those reported here may stem from either a greater degree of purity of our final product or differences in the characteristics of the interferon produced in the two virus-cell systems.

Structure of pyruvate kinase and similarities with other enzymes: possible implications for protein taxonomy and evolution

Michael Levine*, Hilary Muirhead†, David K. Stammers‡ & David I. Stuart

Molecular Enzymology Laboratory, Department of Biochemistry, University of Bristol, Bristol, UK

The structure determination of pyruvate kinase shows that each subunit of the tetrameric molecule consists of three domains. The largest of these domains has a remarkable similarity to the structure of triosephosphate isomerase. Another domain shows similarities to many other nucleotide binding proteins. We discuss these similarities and their implications for current arguments on protein taxonomy and evolution.

We present here results from our X-ray determination of the three-dimensional structure of cat muscle pyruvate kinase (PK) at 2.6 Å resolution which may bear on questions of protein taxonomy and evolution. The X-ray data were collected photographically using an Arndt-Wonacott rotation camera¹, and phase angles were estimated by the method of isomorphous replacement with anomalous scattering measurements using three derivatives. Full experimental details will be published elsewhere.

The high resolution structures are known for about 50 proteins and certain patterns of structural similarity have appeared in a large proportion of these. Their close correlation with functional similarities has led some workers to propose evolutionary schemes for these proteins^{2,3}, although others have suggested that there are only a limited number of stable structures from which proteins are constructed^{4,5}. In the globins and some serine proteases close correspondence in tertiary and primary structure, as well as function, strongly suggests divergence from an ancestral gene^{2,3}. Amongst the dehydrogenases the sequences differ, but the dinucleotide binding domain forms a common structural feature^{6,7} and divergence has been suggested here too. The observation that the 'mononucleotide binding fold' (mnbf) defined as one half of the dehydrogenase NAD binding domain, namely three parallel strands of β sheet and two interconnecting α helices (see Fig. 2e), is common to many other nucleotide binding proteins led Eventoff and Rossmann to propose that this may be an important evolutionarily conserved unit in the kinases⁸. (We shall use the term mnbf to designate this structure without implying any binding properties).

Our studies on PK have shown that the part of the structure involved in the binding of substrates and cofactors bears a striking similarity to the structure of triosephosphate isomerase (TIM)^{9,10}, an enzyme which does not require nucleotides, and is quite unlike the known structures of the other kinases¹¹⁻¹⁴. Another part of the molecule resembles the mnbf and nucleotides bind here but in a novel fashion.

Structure of pyruvate kinase

Details of the structure of one subunit of the PK molecule are shown in Fig. 1. Each subunit comprises some 500 amino acid residues and the molecular weight of the complete molecule, consisting of four identical subunits related by twofold axes as shown, is about 240,000. The polypeptide chain is folded into three distinct domains which are shown schematically in Fig. 1. Domain A is the largest, composed of about 220 residues, and contains a cylindrical β sheet of eight parallel strands. Adjacent strands are connected by α helices which form an outer cylinder coaxial with the first. This is shown in stereo in Fig. 2a and differs from the interpretation of the 3.1-Å map in that an extra strand of β sheet has been located¹⁵. This folding pattern has been observed previously in TIM⁹. To compare these two structures a computer search procedure similar to that of Rossmann and Argos¹⁶ was carried out (Table 1 columns 5-10). A detailed comparison of the arrangement of β sheet and α helix in the two structures is shown in Fig. 2 a-d. To represent this on a two dimensional surface the α -carbon coordinates have been expressed in cylindrical polar form thereby effectively 'unwrapping' the barrel (Fig. 2 c, d). Between the third strand of β sheet and third helix of domain A the chain folds up into domain B, where about 100 residues have been located so far. As can be seen in Fig. 2, domain B occurs in the same position as the largest loop in TIM. Domain B does not seem to consist of α/β structure¹⁷, the main secondary structural feature being anti-parallel β sheet. In TIM the chain terminates at the end of the final helix of the barrel whereas in PK the chain continues for about another 120 residues forming domain C. The first section of domain C comprises two long anti-parallel α helices. The rest of the chain is folded up into a five-stranded β sheet flanked by α helices. The first three strands of sheet and two inter-connecting α helices form the well known mnbf. The third helix leads to the fourth strand of sheet and the last strand lies between strands 1 and 4 and anti-parallel to them. The remarkable similarity of part of domain C to the first mnbf of lactate dehydrogenase (LDH) is illustrated in Fig. 2e.

Comparisons of structure and function

The comparisons of these folding patterns were quantified using the computer search procedure referred to above and the results are given in Table 1 columns 5-10. This shows that the similarity in fold between TIM and domain A of PK is more significant than that between the dehydrogenases. A part of domain C agrees as well with the mnbf of LDH as does phosphoglycerate kinase (PGK), but, the mnbf's of the dehydrogenases LDH and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) agree rather better amongst themselves.

Substrate and cofactor difference maps have been published at 6-Å resolution previously for PK¹⁸. Phosphoenolpyruvate (PEP) lies at the carboxyl end of the barrel close to its axis and interacts with several large side chains. The

Fig. 1 Exploded diagram of the pyruvate kinase subunit. *a-d* Are all drawn from the same viewpoint. *a*, Schematic representation of the domain structure of the subunit. The three domains are labelled A, B and C. The three intersecting dyad axes relating the four subunits of the tetramer are labelled *x*, *y* and *z*. S1 marks the active site and S2 the secondary nucleotide binding site. *b-d*, Simplified representations of the course of the polypeptide backbone in domains A, B and C respectively. I and II are the connections between domains A and B while III links A and C. In (*b*) and (*d*) α helices are shown as cylinders and the strands of β sheet as arrows (pointing towards the carboxy end of the strand). Since the electron density for domain B is weaker than that for the other domains the structure shown in (*c*) should be regarded as provisional. Most of the elements of secondary structure (almost exclusively β sheet) are clear but the connections are uncertain and hence the strands are not shown as arrows.

Columns (3) and (4): these measures are limited by being based on the extant structures and do not consider the significance that, for instance, 2 structures are eight-stranded α/β barrels, whatever the connections. However, since this measure has been used before in assessing the significance of structural similarities the numbers allow our results to be related to previous discussions, on the basis of simple, explicit assumptions. Col. (3), Schulz & Schirmer²² calculated the number of distinct topologies which could be obtained by re-connecting the helices and β sheet strands of a given α/β structure. In their treatment the 'topology' is fully described by strand sequence in the sheet and the above below pattern of connections. For n strands of sheet there are $n!$ arrangements and 2^{n-1} ways of arranging the interconnecting helices above or below the sheet. Of these topologies half are superimposable on the other half by twofold rotation. Thus there are $n! \times 2^{n-2}$ distinct topologies. Col. (4), Sternberg and Thornton⁶, and Richardson⁴ have pointed out that sheet and helix in α/β structure are nearly always connected in such a way as to form a right-handed spiral. This reduces the number to approximately $n!/2$. For an eightfold barrel, assuming that the helices, for steric reasons, cannot be on the inside, we can choose the first strand anywhere. There are then seven choices for the second and so on. There are thus $(n-1)!$ distinct topologies. Since the barrel is a closed structure the restriction of Sternberg and Thornton does not affect this total. Cols (5)–(10), structure 2 is rotated through all possible angles and compared to structure 1 for each position (Rossmann and Argos¹⁰). The likelihood that residue i in structure 1 is equivalent to residue j in structure 2 is expressed as the probability $P_{ij} = \exp(d_{ij}^2/E_1^2) \exp(S_{ij}^2/E_2^2)$. d_{ij} = the distance between $c_{\alpha(i)}$ and $c_{\alpha(j)}$ in the current orientations of the molecules $S_{ij}^2 = (d_{ij} - d_{i+1,j+1})^2 + (d_{ij} - d_{i-1,j-1})^2$ and gives a measure of how similar the shapes of the chains are on either side of $c_{\alpha(i)}$ and $c_{\alpha(j)}$. By varying the values of E_1 and E_2 we can adjust the relative weights attached to each of these two measures in assessing the overall similarity of two stretches of polypeptide chain. P_{ij} is calculated for all values of i and j (ref. 23). We choose that set of (i,j) for which the sum $\sum P_{ij}$ ($P > 0.05$) is maximum and i and j both increase from one pair to the next along the chains. Equivalent residues are then those residues which have $P_{ij} > 0.05$, the physical significance of this cut off being determined by the particular values that are used for E_1 and E_2 . Orientation and translation parameters are found for which the number of equivalences is largest²⁴. These numbers are in Col. (5) and expressed as percentages of each structure in Col. (8) and (9). The rotation matrix which brings TIM (protein data bank coordinates) into the same orientation as PK is:

$$\begin{array}{ccc} -0.7376 & 0.5956 & -0.3182 \\ -0.5214 & -0.2029 & 0.8288 \\ 0.4291 & 0.7773 & 0.4602 \end{array}$$

Fig. 2 Stereo diagrams showing the results of structural comparisons of pyruvate kinase with other enzymes. The α -carbon backbone is represented. The pyruvate kinase coordinates are as measured from a 1 cm/ \AA skeletal model. *a*, Domain A of PK. *b*, TIM, rotated so as to give the overall 'best fit' as defined in Table 1 when superimposed on domain A of PK. Note that the cross section of the barrel is more elliptical than in PK. *c*, Domain A of PK unwrapped. The cartesian coordinates of the α carbons have been transformed into cylindrical polar coordinates r , z and Φ where the cylindrical polar axes are as shown in (*a*). r is the distance along the azimuthal vector, Φ is the azimuthal angle and z is the distance along the cylinder axis. R is the approximate radius of the β sheet cylinder. $R = 8.5 \text{ \AA}$. *d*, TIM unwrapped as in (*c*). $R = 8.0 \text{ \AA}$. This shows clearly any small differences in the orientation of the structure elements. *e*, The mnbf LDH (dotted line) compared to part of domain C of PK (full line).

density for Mn-ATP lies radially perpendicular to the barrel axis so that the end of the density interpreted as the terminal phosphate overlaps the PEP binding site and the other end is between strands 3 and 4 of the barrel β sheet. This is unlike PGK where the 3-phosphoglycerate (N. Walker, personal communication) and nucleotide^{11,12} lie along the end of the β sheet. However, the PEP density is in a similar position to that of the substrate dihydroxyacetone phosphate (DHAP) in TIM⁹ (see Fig. 4). In suitable conditions ADP can be bound at a site between domains A and C in such a position that it interacts with the amino ends of β strands of the barrel and the carboxy end of the second helix of the mnbf in domain C. Surprisingly it is not at the carboxy end of the β sheet of this structure (Fig. 1).

Since kinases are grouped together on the basis of phosphoryl transfer from ATP the similarity between domain A of PK and TIM is at first sight unexpected. However, there are in fact similarities in the reactions of the two enzymes if we consider enolisation of the 2-keto-triose substrates. In PK, PEP is produced by deprotonating and phosphorylating pyruvate, while in TIM the formation of glyceraldehyde-3-phosphate is accomplished through deprotonation of dihydroxyacetone phosphate. It has been proposed that in each case a base on the enzyme participates in the deprotonation reactions. The existence of a *cis*-enediol intermediate has been demonstrated for TIM^{19,20}. Rose has shown that in the reaction catalysed by PK, enolisation of pyruvate may be decoupled from phosphorylation²¹. Figure 3 illustrates the similarity in this part of the proposed mechanisms.

We have already noted that the substrate binding sites are similarly located on the axis of the barrel in both PK and TIM. The next question to ask is are the active sites of the two proteins similar? Since the primary structure of PK is unknown we cannot identify the side chains with any certainty. We present the side chains which appear in the electron density map in the region where substrates bind, together with the corresponding region of the TIM model (Fig. 4). From this diagram it seems that there are side chains in the active sites of both PK and TIM that are associated with corresponding β -sheet elements. As far as can be seen the sizes and orientations are similar. Thus, as well as comparing PK with the other kinases, it may be useful to include consideration of the fine differences between PK and TIM in studies of the mechanisms of these two enzymes.

Fig. 3 The proton transfer reactions catalysed by pyruvate kinase and triose phosphate isomerase. In each case B is a base on the enzyme. Enol-pyruvate can be considered to be an enzyme-bound intermediate in the PK reaction²⁶ and a *cis*-enediol intermediate has been implicated in the TIM reaction²⁰.

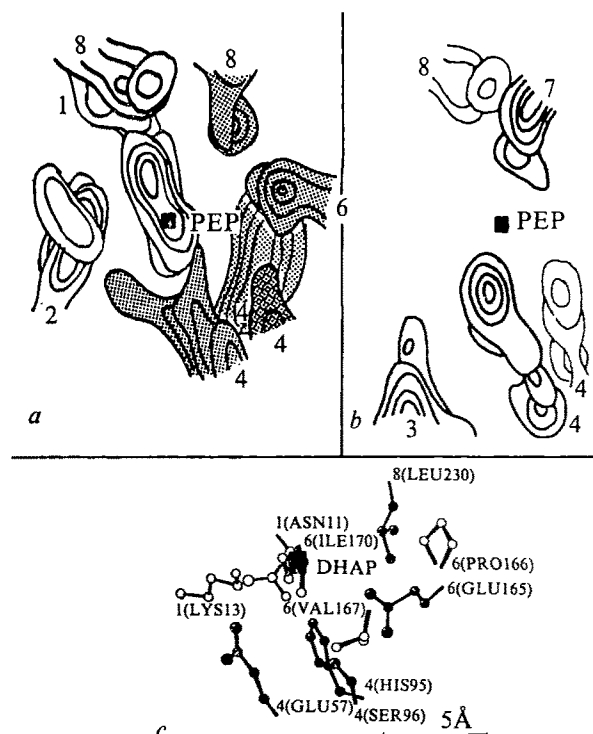

Fig. 4 *a, b*, Pyruvate kinase active site. The electron density corresponding to side chains close to the binding site of PEP is shown, this is the area marked S1 in Fig. 1. The direction of view is along the axis marked y in Fig. 1 with the z axis horizontal. Each side chain is numbered to indicate which element of the β -sheet barrel it is attached to. The n th element of the barrel is defined as containing all residues between the beginning of the n th strand and the end of the n th helix. In the electron density map, the unit cell of the crystal is sectioned perpendicular to the y -axis. The thickness of each section is 1.25 Å. The PEP site is centred on section 38 and is marked ■. (*a*) Shows a composite of sections 32 to 38 and *b*, of sections 38 to 42. The side chains only are shown, the main chain having been left out for clarity. *c*, Triosephosphate isomerase active site. The orientation corresponds to that of (*a*) and (*b*) and the atomic coordinates for the side chains of the residues close to the DHAP position are shown. C₂ of DHAP is marked ■. The labels show the element of barrel to which each residue is attached with the residue type and number given in parenthesis. The scale of this diagram is the same as (*a*) and (*b*). The residues shaded in (*a*) seem to occupy analogous positions to those with filled atoms in (*c*) and it will be seen that the secondary structural elements that they are attached to correspond. Phillips *et al.*²⁶ have shown that the proposal, based on the X-ray diffraction results, that Glu 165 is the base implicated in the mechanism (Fig. 3) is consistent with other biochemical evidence. In comparing the two diagrams note that the barrels are not exactly the same shape in TIM and PK (Fig. 2*a, b*) and consequently groups attached to different strands are displaced relative to each other. Note also that three of the residues of the fourth sheet-helix element seem to be in similar relative positions in the two structures. These three residues in TIM²⁶, His 95, Ser 96, Glu 97, are all members of the group of residues implicated in the active site.

Pyruvate kinase and evolution

Our results suggest that domain A of PK and TIM may have evolved from a common ancestor but contradict the idea⁵ that the appearance of the mnbf in an enzyme implies the binding of a nucleotide in the same fashion as in the dehydrogenases and its evolutionary conservation for this function alone. Thus if one considers that any three consecutive strands of the eightfold barrel comprise a mnbf⁹ then the two nucleotide binding sites in PK are both associated with a mnbf. However, the manner of binding is quite different to that found in the dehydrogenases. At the active site the nucleotide is bound at the carboxy end of the β sheet as in the dehydrogenases but is orientated along a radius instead of along the edge of the sheet. At the secondary site it is not even near to the β sheet. It could be

argued^{4,5} that a structure like the mnbf is likely to form in PK if only because it is so highly probable in such a large α/β structure. We feel that although this may be true it tends to divert attention from interesting considerations of structure and function and their possible relation to evolution. It may be that proposals for simple evolutionary relationships between structures should at present be confined to functional domains as in the dehydrogenases or domain A of PK and not applied to stable substructures such as the mnbf which could conceivably be dissected out from them. If the similarities between domain A and TIM do imply a divergent evolutionary relationship rather than convergent evolution then it would seem that either PK is a composite of parts which had separate evolutionary histories before their joining together to make the modern enzyme or TIM is derived from a fragment of an ancestral protein. We would still have to account for the derivations of domains B and C in PK. It is also apparent that the kinases do not form such a closely related group of structures as the dehydrogenases. All known kinase structures consist of α/β units¹¹⁻¹⁴. PGK^{11,12} possesses the 'dinucleotide binding fold' of LDH and apparently binds the nucleotide in a similar manner. PK, hexokinase¹⁴ and adenyl kinase¹³ all differ.

The basic difference between the PK/TIM homology and those observed previously is that whereas for, say, the dehydrogenases the function of the postulated conserved gene is characteristic of a group of enzymes accepted as belonging to a single class, in the PK/TIM case, the function conserved would cut across the two categories 'kinase' and 'isomerase'. As more protein structures are revealed the present categories may therefore be found

inadequate and other groupings may emerge which reflect both similarities of domain structure and the different aspects of the function. The problem posed by the structural diversity of the enzymes now classed as kinases may then disappear.

We thank Dr John Williams for helpful discussions, Dr I. A. Wilson and Professor D. C. Phillips for use of unpublished results, the Protein Data Bank for atomic coordinates of proteins and the SRC for support.

letters to nature

Dual character of the rapid burster and a classification of X-ray bursts

DIFFERENT kinds of X-ray bursts, as observed from the rapid burster (MXB1730-335) (refs 1, 2) and from other sources³⁻⁵, can be classified into two types which, as we will show, may have different origins and production mechanisms. Type I bursts occur at intervals of hours, days or longer. Their spectra almost always soften during burst decay, and their average spectrum during the first few seconds of a burst is generally harder than the spectrum of the associated persistent X-ray emission (if present). Type II bursts occur at intervals of several seconds to minutes, and their spectra do not soften during burst decay. The rapid burster¹⁻⁶ can produce up to several thousand type II bursts per day. Type II bursts may perhaps also be produced by other X-ray sources such as Cyg X-1 (ref. 7). Type I bursts are produced by all other burst sources reported so far³⁻⁵. Here we will show that the rapid burster also produces type I bursts.

Between 1977 September 27.27 and October 2.76 UT we observed the rapid burster (MXB1730-335) (ref. 1) with the y -axis detectors of the SAS-3 observatory⁸. The burst rate varied from $\sim 50 \text{ h}^{-1}$ to $\sim 250 \text{ h}^{-1}$, the burst durations from $\sim 3 \text{ s}$ to $\sim 10 \text{ s}$ (ref. 9).

In addition to the rapidly repetitive bursts (up to several thousand per day), henceforth called 'rapid' bursts, we detected 19 bursts which have a different appearance: (1) they

last longer ($\sim 30 \text{ s}$) than the rapid bursts; (2) they occur out of sequence of the rapid burst pattern, grossly violating the $E-\Delta t$ relations for rapid bursts^{1,4,6}; (3) their spectra soften during burst decay unlike the spectra of the rapid bursts; and (4) their time-averaged spectra during the first $\sim 10 \text{ s}$ are often harder than those of the rapid bursts.

Figure 1 shows, in addition to many rapid bursts, three of the 19 'special' bursts which were recorded in the horizontal tube system⁸ (1.3-12 keV). In several cases we detected a rapid burst coincident with a special burst (Fig. 1b and c), as would be expected (chance coincidence) if the two are unrelated. This may indicate separate origins and possibly different mechanisms for the two types of bursts.

Based on the similarity of the relative counting rates in the independent y -axis detectors for the special and rapid bursts, the 19 special bursts must have come from within $\sim 10 \text{ arc min}$ of MXB1730-335. We believe that they actually came from MXB1730-335. They did not come from MXB1728-34 (at $\sim 0.5^\circ$ distance)¹⁰ as we detected 11 bursts from this source with markedly different ratios of the counting rates in the y -axis detectors than the special bursts.

Figure 2 shows the data from five energy channels of the bursts shown in Fig. 1a. The softening of the spectrum during the decay of the special burst is clearly visible, but it is absent in the five rapid bursts. Also, unlike the rapid bursts, the special burst is very distinct in the 8-19 keV channel.

Table 1 lists the times when the 19 bursts were detected. The burst intervals between the detected bursts are plotted in Fig. 3.

Fig. 1 Three sections of SAS-3 data from the horizontal tube detectors (sum of three channels, 1.3–12 keV). Each section contains a 'special' burst: *a*, burst 6; *b*, burst 4; *c*, burst 12 (see Table 1). The counting rates would have been somewhat higher if the rapid burster had been exactly in the centre of the field of view. Correction factors for the burst data are 1.11 (*a*), 1.05 (*b*) and 1.18 (*c*). The special bursts (type I) arrive out of sequence of the rapidly repetitive bursts (type II), which are independently numbered. They have approximately the same height as the 'rapid' bursts, but they last considerably longer (~30–40 s). In (*b*) and (*c*) a rapid burst occurs simultaneously with a special burst. Note in (*c*) that the special burst (12) is followed by a large rapid burst (no. 12) ~45 s later. Such a coincidence was observed four times (see text).

The minimum detected interval was 2.9h, the maximum was 20.4h. Some bursts were almost certainly missed due to Earth occultation.

There are no obvious regularities in the burst intervals (Fig. 3), but it is possible that a few semi-regular series were present with intervals near 3–4h (see dashed lines in Fig. 3). The regularity was clearly broken at times. We should point out that the burst intervals can, during certain periods, become synchronised (in phase) with the 30 min occulted portion of each 95 min orbit. For example, the mean burst intervals between bursts 8 and 13 (day 416–417 in Fig. 3) may have been ~3.1h (r.m.s. jitter 15%), which is almost exactly twice the orbital period (1.57h). Therefore, the probability of missing four bursts in a row (near day 418; Fig. 3) is not necessarily low. Nevertheless, to fit all 19 bursts in one semi-regular series with intervals of ~3–4h, spanning the entire 5.5d observing period, would require at least 18 bursts to have been blocked by the Earth; this probability is negligibly small.

Between September 30.0 and 30.8 (UT) 1977, the rapid burst rate was very high, ~160–220 bursts h^{-1} , compared to ~95 bursts h^{-1} averaged over the rest of the observation. During this period, the bursts were nearly equal in size, except that in every orbit, 1–4 larger rapid bursts were emitted (average ~2.6 h^{-1}) with 3–5 times more energy than the other bursts. Such large bursts were occasionally detected during the rest of the observation, but only in ~10% of the orbits. Of 45 such large rapid bursts detected in the entire 5.5 day observation, 25 were detected in the September 30.0 to 30.8 period. During this ~19 h period (~12.7 h of unocculted data on the rapid burster) we detected four special bursts (10–13 in Table 1), each of which was followed within ~80 s by such a large rapid burst (Fig. 1c). Given the observed rate of special bursts (~0.32 h^{-1}) and of large rapid bursts (~2.6 h^{-1}) during this interval, the expected number of such close coincidences is ~0.02 h^{-1} , or ~0.25 during the entire interval. The probability of observing four such close coincidences is thus ~ 10^{-4} . We therefore conclude that there is some causal connection between the special bursts and the rapid burst, and thus that the special bursts came from MXB1730–335.

The rapid bursts from the rapid burster are of type II, and are different from type I bursts in that they occur at a much higher

rate and do not show spectral softening during burst decay. The 19 special bursts are type I bursts. They resemble the bursts observed from many other sources^{3–5} in that: the time intervals between bursts (hours) are comparable; the burst recurrence patterns are similar (refs 5, 11, 12 and SAS-3 unpublished results); and the softening of the spectra during burst decay observed in the special bursts is characteristic of X-ray bursts from almost all sources^{3–5}.

The detection of type I bursts from the rapid burster may indicate that the rapid burster, in spite of its unique behaviour, is physically similar to other burst sources.

We have examined our March–April 1976 data from the rapid burster for the presence of special bursts. We found none in the March data but we found six bursts in the April data that are very similar to special bursts. They were in a semi-regular sequence with average burst intervals of ~3.8h (r.m.s. jitter 10%), and the spectral softening during burst decay was very clear in at least two cases. The horizontal tube xenon detectors⁸ were turned off at the time; we therefore cannot tell whether the spectra of the six bursts were harder than that of the rapid bursts.

The rapid burst pattern was very similar in April 1976 and September–October 1977 (regular burst intervals) but very different in March 1976 (intervals differed by a factor of ~100) (refs 1–4). This may well be why special bursts were detected

Table 1 Times that special (type I) bursts were observed from MXB1730–335 between 1977 September 27.267 and October 2.760 (UT).

Julian Day—2443400 days			

A type I burst occurring at 18.9854 UT was discovered in the data after this letter was submitted. This is not included in this table or in Fig. 3.

Fig. 2 Spectral information (five energy channels) for the data shown in Fig. 1a: a, 1.3–3 keV; b, 3–6 keV; c, 6–12 keV; d, 8–19 keV; e, 19–27 keV. Notice that the spectrum during burst decay of the special (type I) burst softens. This softening is very common in bursts from other sources, but it is absent in the rapid (type II) bursts. The special burst is clearly visible in the range 8–19 keV, and thus its mean spectrum (first ~ 10 s) is harder than that of the rapid bursts.

in April 1976 and September–October 1977 but not in March 1976. We did, however, detect 23 unusual bursts in March 1976 of which 17 were previously reported as ‘anomalous’ bursts by Ulmer *et al.*². They occurred at irregular intervals and all were preceded by a very energetic rapid burst. This established that the anomalous bursts came from the rapid burster and that there is a causal relation between the rapid and the anomalous bursts². The anomalous bursts have some features in common with the special bursts, and there are some differences. Both have durations of ~ 30 s, and both occur out of sequence of the rapid burst pattern, grossly violating the $E-\Delta t$ relations for rapid bursts^{1,4,6}. The ratio of the time-averaged flux of rapid bursts and special bursts was ~ 120 . This is similar to the ratio of ~ 140 for rapid bursts and anomalous bursts. The main differences between anomalous and special bursts are that anomalous bursts have lower peak luminosity compared to the most energetic rapid bursts, longer rise times, a softer mean spectrum,

Fig. 3 Intervals between detected bursts are shown as black dots. \circ , Indicate the observed intervals divided by two, three, four and so on (bursts can be missed as a result of Earth blocking). The numbers next to the open circles indicate the number of possibly missing bursts. Semi-regular burst series may have occurred near day 415 (dashed line), between day 416 and 417, and near day 419 (dashed line) (see text).

and they probably lack the spectral softening during burst decay (although, because anomalous bursts are relatively weak, this latter point is not certain). We do not know whether anomalous and special bursts are related in that they are caused by the same phenomenon but we suspect that they are.

White *et al.*⁶ have discussed the previously well known breakdown of the linearity in the $E-\Delta t$ relation of rapid bursts (first reported by Lewin in December 1976) (ref. 4). They show four days of data of the rapid burster as observed in April 1977 with Ariel V. There are no special bursts in their data. Anomalous bursts might be present in the Ariel V data. But, the sensitivity of the Ariel V observations is probably too low to recognise them as the peak luminosity of anomalous bursts is $\sim 1/3$ that of rapid bursts² (but see note added in proof).

The rapid burster seems to have a dual character. On one hand, it can produce type I bursts similar to those observed from other burst sources. On the other hand, quite independently, it can produce type II bursts in rapid succession (up to $\sim 4,000$ per day). Bursts of type I and type II can occur simultaneously (Fig. 1b and c) which may indicate separate origins and possibly different mechanisms for their production. The two types of bursts can influence one another, however.

In order to find out whether there are times when the rapid burster produces only type I bursts, we examined several weeks of data from the nearby source MXB1728–34, during times that no rapidly repetitive bursts were observed from MXB1730–335 (refs 13–15 and SAS-3 unpublished results). We did not find any. This, of course, does not prove that it never happens, and we plan to observe the rapid burster frequently after the rapidly repetitive type II bursts have ceased. This is expected some time in November 1977, if the duration of rapid burster activity is the same as was observed in the springs of 1976 and 1977 (refs 1, 6, 15–17).

The ratio of the time-averaged luminosity of rapid bursts

(type II) to that of both 'special' bursts and 'anomalous' bursts (type I) was ~ 130 . This is comparable to the ratio of time-averaged persistent X-ray emission and time-averaged type I burst emission for many burst sources³⁻⁵. This opens up the interesting possibility (suggested by J. Doty, personal communication) that in MXB1730-335 the persistent X-ray emission as observed from many burst sources manifests itself in the form of rapidly repetitive type II bursts. In support of this, we point out that the mean burst spectra of rapid bursts are similar to the spectra of the persistent emission from most sources that produce bursts³⁻⁵. Also, the mean spectra (first ~ 10 s) of special (type I) bursts are harder than those of the rapid (type II) bursts just as the mean spectra of type I bursts from most sources are harder than that of the persistent emission³⁻⁵.

If this idea is correct, it may remove one of the main problems with thermonuclear flash models of X-ray bursts (ref. 5 and references therein), which predict the ratio of time-averaged steady luminosity to time-averaged burst luminosity to be $\lesssim 10^2$. No persistent X-ray emission has been detected from the rapid burster^{1,6}, and the ratio of steady luminosity to time-averaged type II burst luminosity has been measured to be as low as < 0.2 (ref. 6). But, if the rapidly repetitive type II bursts take the place of the steady emission and type I bursts have a thermonuclear origin, then the equivalent ratio would be ~ 130 for MXB1730-335.

Type II bursts as observed from the rapid burster are probably the result of instabilities in the accretion flow. The more common type I bursts may be the result of thermonuclear flashes or they too could result from some kind of an instability in the accretion flow (ref. 5 and references therein).

The brief flares as observed from the binary sources Cyg X-1 (ref. 7), GX304-1 (ref. 18) and LMCX-4 (ref. 19) meet the phenomenological definition of type II bursts. We do not discount the possibility that those flares are produced by the same mechanism that produces type II bursts in the rapid burster.

We thank Lynn Cominsky, John Doty and Claude Canizares for helpful discussions.

Note added in proof: We are informed by K. Mason (personal communication) that Ariel V would have detected anomalous bursts of the strength reported by Ulmer *et al.*² if they had occurred. Therefore, the rapid burster was producing neither special nor anomalous bursts in April 1977.

The nature of Aquila X-1

THE unusual X-ray source Aquila X-1 (=4U1908+00; =2S1908+005) has been observed for almost a decade, and represents a singular link between the 'steady' galactic X-ray stars and the flaring and transient sources. Although this object normally has an X-ray flux of the order 1-10% of the Crab Nebula¹⁻³, approximately once per year it undergoes an intense outburst to a level comparable to the Crab²⁻⁴. A 1.3-d X-ray periodicity during the outburst has also been suggested⁵. A recent very accurate X-ray position for Aql X-1⁶ has permitted the optical identification of the source⁷ using primarily the extensive plate material described by Davidsen *et al.*². We report here photometry and spectroscopy of the counterpart and the stars in the immediately surrounding field, and use these data to arrive at some inferences regarding the nature of this unusual X-ray system.

Photoelectric photometry of nine stars in a 1 arc min field about Aql X-1 was obtained in July and August 1976, using the 2.1 m reflector of the Kitt Peak National Observatory with the Cassegrain computer-photometer. Standardisation of these *UBV* data was achieved through observations of standard stars from the compilation of Landolt⁸; the objects observed were in the range $12.4 < V < 17.1$, $13.1 < B < 18.3$. Spectroscopy of nine stars in the field, partially overlapping with the photometric sample and ranging $12.4 < V < 15.2$, was obtained in November 1975 using the Mk I multichannel spectrometer⁹ at the 1.3 m reflector of the McGraw Hill Observatory. Spectral types were derived for these stars through comparison with spectral standards¹⁰ and through H α equivalent widths¹¹.

We have also obtained photographic photometry of the optical counterpart in quiescence and outburst. The quiescent data consist of direct photographic plates obtained with the 0.9 m Crossley reflector of the Lick Observatory in August and October 1977. These plates were calibrated through iris photometry of the stars in the photoelectric sequence described above, providing a direct comparison sequence extending to $V=17$, $B=18$, and through a transfer from the M15 field described by Sandage¹², which is photoelectrically calibrated to $V=22$, $B=23$. This combined photoelectric-photographic calibration of the Aql X-1 field is considerably more accurate than a standard photographic transfer, judging from the scatter in the magnitudes derived for the standard stars, which is of the order 0.10-0.15 mag even for the faintest objects. The outburst data consist of the Palomar Observatory Sky Survey prints which remarkably show Aql X-1 near maximum light on the date (August 23-24 1951) they were exposed. The *B* and *R* magnitudes of Aql X-1 on these prints were determined by measuring on a 2-axis Mann measuring engine image diameters of the comparison stars discussed above.

We find that for the Aql X-1 counterpart in quiescence, $V=19.4 \pm 0.15$, and $(B-V) \gtrsim 1.0$; a *B* image is only barely detectable on our plate material. During outburst we find $B=18.41 \pm 0.04$, $R=17.37 \pm 0.24$. Using a colour equation applicable to the Sky Survey¹³, we infer $(B-V)=0.7 \pm 0.2$. An uncalibrated outburst plate described by Thorstensen¹⁴ indicates that the full range of variability may in fact be slightly larger, as in the *B* band the counterpart reached a brightness comparable to star no. 3 in the chart of ref. 6. For that star our photoelectric data yield $B=17.8$. Assuming a reasonably constant colour near the outburst peak, we adopt $V=17.1$, $(B-V)=0.7$ for the outburst state. The large range of inferred photometric variability, together with the simultaneity of two X-ray and optical outbursts⁷ makes the identification of the optical counterpart (star 5 in ref. 6) secure.

Our photometry and spectroscopy of the stars in the immediately surrounding field yield information on the interstellar extinction in this direction. For the stars with spectroscopy, we used our photoelectric or photographic magnitudes and colours to estimate colour excesses and distances; six of

these objects prove to be foreground K stars and thus not distant enough to provide a useful probe. For three additional stars with photoelectric *UBV* data but no spectra, the 'Q' method¹⁵ indicates *B* spectral types, again permitting extinction and distance estimates. The six stars for which we have useful data span a range in distance of 0.3–5 kpc and in A_V of 1.5–4.4 mag. We find these data to be consistent with an exponential model¹⁶ for the distribution of dust perpendicular to the galactic plane, and with the parameters given by Allen¹⁷ of $A_V/d = 1.9 \text{ mag kpc}^{-1}$ in the plane and scale height $H = 130\text{--}190$ pc. The line of sight to Aql X-1 breaks out of the dust layer at a distance of 1.9–2.7 kpc and has a limiting visual extinction A_V of 4–5 mag in this model.

Using this model for the interstellar extinction, we have transformed our observed brightness and colour of Aql X-1 during quiescence and outburst to luminosity and intrinsic colour as a function of assumed distance. The spectral observations¹⁴ suggest a quiescent spectral class near K0. Our quiescent brightness data place dwarf stars of this approximate spectral class at distances between 1 and 2 kpc. Giant stars of the observed spectral class are ruled out by the colours and our reddening against distance relation. In particular, a K0 dwarf at a distance of 1.6 kpc is in good agreement with all the data, and implies an outburst X-ray luminosity far below the Eddington limit.

The existing data, though fragmentary, have interesting implications. The absence of emission lines in the quiescent spectrum¹⁴, despite the detection of an absorption feature, emphasises the difference between Aql X-1 and the dwarf novae, which have emission spectra at all times. This is in contrast to the suggestion⁴ that Aql X-1 may be similar to the dwarf novae. Most striking, however, is the high ratio of X-ray to optical intensity. At maximum light, using our *V* magnitudes and the observed X-ray fluxes of Kaluzienski *et al.*⁴, we find for this ratio a value of about 5,000; in the quiescent state, the ratio is lower but still at least 500. These values should be compared to other identified X-ray sources; the largest value is probably that of Sco X-1, which has a ratio of about 1,000 (see ref. 18). Aql X-1 is even more outstanding than this extra factor of 5 indicates, because in Sco X-1 the visible light source has a temperature $\sim 30,000$ K and a bolometric correction of several magnitudes, probably reducing the bolometric X-ray to optical ratio to $\sim 10^2$. Our colour measured for Aql X-1, together with the indication¹⁴ of a late G or early K type spectrum when quiescent, suggests a reddening $E(B-V)$ of a few tenths of a magnitude and a small bolometric correction during outburst. Correction for extinction decreases the outburst X-ray to optical ratio, but probably not below 500.

The fact that the quiescent spectrum¹⁴ is a late-type absorption spectrum implies that most of the observed optical luminosity is generated within the star. The photospheric opacity of a K dwarf, for example, is about $0.1 \text{ cm}^2 \text{ g}^{-1}$, less than the opacity of matter to any X-rays. Therefore X-ray heating sufficient to substantially affect the atmospheric heat balance during quiescence would produce a strong chromosphere and an emission spectrum, as in Sco X-1^{18,19}; the absence of these implies that the atmosphere is heated from within the star. This is consistent with the fact that the X-ray brightness increases an order of magnitude more than the visible brightness from quiescence to flare.

An X-ray to optical luminosity ratio of 500 implies, in the conventional semidetached Roche binary model, that the companion's radius is about 0.1 of the separation²⁰; equivalently, the X-ray source is about 100 times more massive than its companion. This conclusion is independent of the distance, except through the extinction, but requires that the X-ray radiation should not be highly anisotropic. Three possible solutions to the problem posed by the small size of the companion are a companion of less than stellar mass, a supermassive X-ray source, or abandonment of the assumption that the system is semidetached. The first is ruled out by the fact that in quiescence the companion's luminosity comes

from within, and the second is possible, but will be thought speculative by most. The third explanation, which we favour, poses the problem of how mass transfer is brought about. Oke²¹ argues that the X-ray transient A0620–00 (=V616 Mon; =Nova Mon 1975) is also a K dwarf and presents a similar problem.

If our suggested model for Aql X-1 is correct, it should show (for favourable inclination) a strong photometric periodicity during outburst, perhaps resembling HZ Her, but not when quiescent. During outburst, there may also be an emission spectrum, as in Sco X-1 and A0620–00. There could be a detectable spectroscopic orbit. With our estimated binary separation, a total system mass of $2M_\odot$ and a dwarf companion, an orbital period of about 2 d is implied, possibly consistent with the 1.3-d X-ray period reported by Watson⁵.

Thus, perhaps the most important implication of the data is that Aql X-1 may be the second known case of a low mass galactic X-ray source where the semi-detached Roche model, previously widely used for these systems, is not applicable. We also have strong evidence that the primary is a dwarf and that X-ray heating is the source of the optical outbursts.

We are indebted to E. A. Harlan for photographic observations. J.I.K. is an Alfred P. Sloan Research Fellow. This work was supported in part by the U.S. National Aeronautics and Space Administration.

γ -Rays from γ Geminorum?

THE γ -ray source CG195 + 4 (Geminga) discovered by SAS 2 and further observed by COS B has a period of 59 s which is increasing at a rate $\dot{P} = 2 \times 10^{-9}$ (refs 1,2). If the periodicity is produced by a neutron star which is spinning down at the observed rate, then the rate at which rotational energy is being lost is $L \sim 3 \times 10^{32} \text{ erg s}^{-1}$ (ref. 3). The observed γ -ray flux of $3 \times 10^{-6} \text{ photon cm}^{-2} \text{ s}^{-1}$ with energy $E > 100 \text{ MeV}$ implies that the distance, d , to the source is given by $d \approx 73 f^{1/2} \text{ pc}$ where $f (\geq 1)$ is the fraction of the total energy output which is emitted as γ -rays. Theoretical studies

of the evolution of binary systems which give rise to the binary X-ray sources have led to the suggestion that, before the neutron star starts to accrete and spin up (that is, before the X-ray source turns on) it spends a comparatively long time being spun down in the weak stellar wind of its companion⁴. This leads us to seek a candidate companion for the γ -ray source which is an early type star at a distance of $\gtrsim 70$ pc. As we report here, the only object which satisfies these constraints is γ Geminorum.

The star γ Gem has $m_v = 1.9$ mag and has been classified as A0IV (ref. 5) and A1III (ref. 6). Parallax measurements yield a distance estimate of $d \sim 30$ pc (ref. 7). We therefore require $f \sim 0.17$. We assume the star to have a bolometric luminosity $L_{\text{bol}} \sim 6 \times 10^{35}$ erg s⁻¹, a mass $M_1 \sim 3M_{\odot}$ and a radius $R_1 \sim 3.5 \times 10^{11}$ cm. If we consider a neutron star orbiting γ Gem at a distance comparable to R_1 then a substantial fraction ($\sim 1/4$) of the primary's stellar wind will be accreted towards the companion at a rate \dot{M}_A .

We assume that the neutron star is strongly magnetic and that its corotation radius ($R_{\Omega} \sim 2.3 \times 10^9$ cm) is roughly equal to the Alfvén radius of its magnetosphere, R_M . The neutron star is in its 'sleeping phase': that is, material is not accreted down to the stellar surface but is, rather, expelled from the vicinity of the Alfvén surface. The energy to do this comes from the rotational energy of the neutron star, and if the material is thrown off at about the escape velocity from the region of the Alfvén radius, $V_M \simeq (2GM/R_M)^{1/2}$, we may write $L \sim GM\dot{M}_A/R_M$. This implies that $\dot{M}_A \simeq 5 \times 10^{15}$ g s⁻¹, so that $\dot{M}_W \sim 2 \times 10^{16}$ g s⁻¹. Considering that mass loss will be enhanced by the presence of a close companion this is a reasonable value for the mass loss rate of a star like γ Gem (ref. 8). Making use of the definition of the Alfvén radius, $B^2(R_M)/8\pi \sim 1/2 \rho_M V_M^2$ where $\rho_M = \dot{M}_A/(4\pi R_M^2 V_M)$ is the density of the gas at R_M , we obtain the surface field (assumed dipolar) of the neutron star to be $B \approx 7 \times 10^{12}$ gauss. We have taken the neutron star to have mass $1 M_{\odot}$ and radius 10^6 cm.

Despite the assumed equality of R_M and R_{Ω} material does not accrete down to the stellar surface because at the low density and the high temperature to which the matter is heated ($T \sim 1/2 m_p v_M^2/k \sim 7 \times 10^8$ K) it cannot cool sufficiently by bremsstrahlung to accrete^{9,10}. The energy loss rate due to bremsstrahlung radiation is about 10^{30} erg s⁻¹ which is much less than L , the rate of energy generation at the magnetosphere. This energy must take the form of bulk motion of the gas and hence the gas is expelled.

To produce the γ -rays we suggest that a fraction of the energy released in the interaction between the gas and magnetic field at R_M is in the form of relativistic electrons with $\gamma \sim 2 \times 10^3$. If about a half of these penetrate the magnetosphere, where they radiate by synchrotron in the extreme ultraviolet (~ 400 Å), the dominant loss process for the remainder is inverse Compton scattering on these ultraviolet photons, resulting in the production of the observed 100 MeV γ -rays. The electron energy-loss timescale for this process, t_{IC} , is less than half the pulse period if the electrons are accelerated only over a fraction $\gtrsim 1/4$ of the magnetosphere. This seems likely, given a non-axisymmetric magnetosphere and, together with asymmetries in the initial velocity distribution of the electrons producing the γ -rays, could give rise to a variation in the γ -ray flux with a period equal to (or half) the rotation period of the neutron star. We may expect the ultraviolet synchrotron radiation to have a luminosity and periodic variation similar to those of the γ -rays. The timescale for γ -ray production by scattering of stellar photons, $t'_{\text{IC}} \sim 10^3$ s $\gg t_{\text{IC}}$.

Taking the binary separation $a \sim 2R_1 \sim 7 \times 10^{11}$ cm, a rough estimate of the orbital period is $P_{\text{orb}} \sim 1.5$ d. Our estimate of the radial velocity of γ Gem would be $\sim 70 \sin i$ km s⁻¹, where i is the orbital inclination. To be consistent with radial velocity observations^{6,7,11}, we may require i to be small. This would also tend to make detection of the doppler shift of the γ -ray pulse difficult. We note that when γ Gem has evolved to fill its Roche lobe and starts to transfer material at a higher rate, the neutron star will turn on as an X-ray source with properties very similar to those of Her X-1 (which consists of a neutron star orbiting an F subgiant with an orbital period of 1.7 d).

Evidence that cosmic γ -ray bursts are galactic

OBSERVATIONS from our latest balloon flight and a burst observed by Nishimura *et al.* combined with our previous results and the observations of Bewick *et al.* provide strong evidence that cosmic γ -ray bursts are galactic. It also seems that the recently discovered X-ray bursts and γ -ray bursts have a common origin. A further 41 h of balloon flight time with the University of California, Riverside (UCR) double Compton scatter γ -ray telescope gave no additional γ -ray bursts. This flight time is added to the earlier 24 h observation of Herzo *et al.*¹ who found three bursts with total energy greater than 1×10^{-6} erg cm⁻² and one burst with total energy greater than 4×10^{-6} erg cm⁻² to give lower values for the number of bursts of

$$\left(8 \begin{smallmatrix} +8 \\ -3 \end{smallmatrix}\right) \times 10^2 \text{ and } \left(3 \begin{smallmatrix} +7 \\ -1 \end{smallmatrix}\right) \times 10^2 \text{ d}^{-1}, \text{ respectively.}$$

Our new observations were carried out on a flight launched from Muskogee, Oklahoma on 24 May 1976 at 0100 UT. The altitude of the observations varied from 3.1 to 7.5 g cm⁻² of residual atmosphere. The γ -ray telescope is described elsewhere^{2,3}. The γ rays were detected in three different modes: first, total neutral counts in the large upper liquid scintillator tank (S1) that is $1 \text{ m} \times 1 \text{ m} \times 12.5 \text{ cm}$; and second, total neutral coincidences between S1 and the lower scintillator tank (S2), $1 \text{ m} \times 1 \text{ m} \times 20 \text{ cm}$. Third, γ rays whose energy and angle were identified by scatters in one of the 28 cells in S1 followed by a scatter in one of the 28 cells in S2. For each of these events the cell identification, energy deposit in S1 and S2 and the time of flight from S1 to S2 were recorded. S1 and S2 were each completely surrounded by plastic scintillator and charged particle events were vetoed with an efficiency of better than 99.99%.

The new UCR cosmic γ -ray burst frequencies are given in Fig. 1 along with other satellite and balloon values. The satellites, Vela, IMP 7 and SAS II report observations mainly for larger bursts of 10^{-5} to 10^{-4} erg cm⁻² because of the small sizes and sensitivities of their detectors. The reported Vela burst frequencies^{4,5} bend over at the lower burst sizes presumably because their trigger mechanism is size dependent. Their burst detection frequency then drops rapidly for the smaller bursts. But, the balloon observations with large areas and high sensitivities are able to observe burst sizes as low as $\sim 10^{-7}$ erg cm⁻². Some balloon observations, limited to times of less than about 24 h, have given upper limits only^{6–8}. The 1σ confidence

upper limit of Carter *et al.*⁸, shown in Fig. 1, falls much lower than the other 2σ upper limits. The 2σ confidence upper limit would be higher than the plotted value by a factor of 3. Cline and Schmidt⁹ argue that it should be plotted at a different position (solid rectangle). However, Carter *et al.*¹⁰ insist that their original position is correct. γ -Ray bursts with energies greater than about 10^{-6} and 10^{-7} erg cm⁻² have been observed over a few days and a few hours, respectively. Bewick *et al.*¹¹ pointed out that their point is compatible with a galactic source distribution. Nishimura *et al.*¹² published information about their burst but its contribution to the burst size distribution is reported here for the first time.

If the sources of the bursts are isotropic, either very close, less than a few hundred pc away, or very far—extragalactic—the burst distributions in size (S) should vary as $S^{-3/2}$. On the other hand, if the bursts are galactic and limited to a disk, they should vary as S^{-1} .

Fig. 1 γ -ray burst frequency distribution. Our points, those of Bewick *et al.*¹¹ and Nishimura *et al.*¹² have error bars of one standard deviation based on a Poisson distribution. The upper limit values are all two standard deviations (95% confidence level) of Gaussian distributions of the backgrounds except for the point of Carter *et al.*⁸ which is 1σ .

The five bursts observed by detectors on balloons along with the observations from satellites at larger burst sizes strongly suggest that the γ -ray bursts are galactic. The larger bursts, seen by satellites, are probably near, within a few hundred pc, and the smaller ones seen by balloons are probably much further away, perhaps thousands of pc.

It is of considerable astrophysical interest to determine whether the recently discovered X-ray bursts¹³ and the γ -ray bursts have a common origin. Their rise times of a fraction of a second and durations of a few seconds seem similar. Although a recent attempt to measure coincidences between the two types of events on the same satellite gave inconclusive results¹⁴, it seems that the evidence supports the same source for the two types of bursts. The γ -ray bursts are then the high energy tails of the low energy X-ray bursts.

We thank the National Scientific Balloon Facility for its balloon launch and NASA, NSF and ONR for their support.

Statistical investigation of compact emitting regions in extragalactic radio sources

EXTRAGALACTIC radio sources of high total luminosity usually contain compact emitting regions. These may be coincident with the optical galaxy or quasar, or they may be situated at the outer edges of extended double structures. Radio interferometers sensitive to structures with an angular scale ≤ 1 arc s have been used at Jodrell Bank to investigate the frequency of occurrence of such compact regions. Large samples of sources, covering a wide range of flux densities, were studied. This work extends to lower flux densities than previous investigations based on observations of sources showing interplanetary scintillations^{1,2}. The frequency of occurrence of compact regions varies as a function of flux density. This is best explained as a cosmological effect involving the strong evolution of source properties with redshift. Several forms of this evolution, similar to those deduced from the radio source counts (see ref. 3), and the relationship between largest angular size and flux density^{4,5} are discussed elsewhere⁶.

This study is based on observations made with the Jodrell Bank-Defford interferometer (127 km baseline) at 408 MHz using two techniques. The instrument has been used as a drift interferometer to observe sources from the Bologna Catalogue^{7,8} in the declination range $29^\circ 30' - 33^\circ$. A total of 713 sources were observed near meridian transit for approximately 3 min each as they moved through the aerial beams. The fringe visibility (γ_T) in position angle $\approx 180^\circ$ was thereby determined for each source. Although γ_T for any source will depend on its detailed structure, the fraction $p(\gamma_T)$ of sources which have $\gamma_T > 0.5$ indicates the frequency of occurrence of compact regions (≤ 1 arc s) emitting over 50% of the flux density. The results of this survey have been examined as a function of flux density by dividing the sources into five samples which have median values of flux density ranging from 2.95 Jy to 0.45 Jy

Table 1 Drift observations of 713 radio sources from the B2 catalogue^{7,8} at 408 MHz

Median flux density (Jy)	Range of flux density (Jy)	No. of sources	Percentage with $\gamma_T \geq 0.5$
2.95	$2 \leq S < 5$	46	17.4 ± 5.6
1.2	$1 \leq S < 2$	126	19.0 ± 3.5
0.83	$0.7 \leq S < 1$	118	24.0 ± 5.0
0.59	$0.5 \leq S < 0.7$	247	19.4 ± 2.5
0.45	$0.4 \leq S < 0.5$	176	21.0 ± 3.1

as indicated in Table 1; errors of one standard deviation arising from counting errors (and from noise in the two lowest ranges of flux density) are shown. Within the errors, $p(\gamma_T)$ is constant at $\sim 20\%$ over this range at flux density.

Results have been obtained over a much wider flux density range by making tracking observations with the same interferometer. Studies have been made of 385 sources selected without bias from catalogues compiled at 408 MHz. Most of the sources were observed for a 9–12 h period within the hour angle range 1400–0900 h. During such a period the resolving power of this interferometer varies by less than a factor of two, but its position angle changes by more than 120° . The maximum fringe visibility (γ_m) from such observations then gives a better value for the fraction of the flux density coming from regions ≤ 1 arc s as it is largely independent of the effects of any double structure in the source or of elongation of the compact components.

These 385 sources have been divided into nine samples with median values of flux density ranging from 29 Jy to 0.047 Jy as indicated in Table 2. Far more information is available about the structures of intense sources than those of the fainter ones, but in order to search for any trend of compactness with flux density it is desirable to use a statistic which can be extracted, with equal reliability and objectivity, for all the sources being studied. The quantity $p(\gamma_m)$ (fraction of sample with $\gamma_m > 0.5$) is suitable and is plotted in Fig. 1. The values of $p(\gamma_m)$ increase from $11.5\% \pm 8\%$ for the most intense sources to $39\% \pm 10\%$ at 1.6 Jy, but then at lower fluxes remain constant at $\sim 30\%$ or possibly show a slow decrease. For the range of flux densities where the results for the drift and tracking

from 0.12 at 20 Jy (408 MHz) to 0.4 at 2.7 Jy (408 MHz) (the flux densities being converted to 408 MHz using a spectral index of -0.7). These results are clearly consistent with our observations above 1 Jy.

A detailed discussion of the present results will be published elsewhere⁶. Using a standard cosmological model and available data on a sample of sources from the 3CR catalogue as a basis for calculation, it is found that the observed relation, an increase in $p(\gamma_m)$ down to 1 Jy, and a constant value or decrease at lower fluxes, is difficult to explain unless there is a strong evolution of source properties with red shift. The calculations give the best agreement with the observations when a strong evolution of source density³ is coupled with a linear size evolution⁶ of the type $l \propto l_0 (1+z)^{-1}$. Linear size evolution has previously been used to explain the observed form of the largest angular size/red shift relation for QSOs¹⁷ and the largest angular size/flux density relation for radio sources in general⁵. This work suggests that it occurs within the compact emitting regions as well.

Fig. 1 The fraction of radio sources observed to emit more than half their flux from regions smaller than 1 arc s, as a function of flux density. Errors of 1σ are shown; these are determined from the numbers of sources in the samples and the distribution of individual values of γ_m within each sample.

Further interferometric observations of weak radio sources are in progress in an attempt to reduce the errors in Fig. 1 for the points below 1 Jy.

We thank many colleagues for help with these observations, and H. Darrah, J. Clarke and T. Muxlow for allowing us to use unpublished data. P. J. R., B. S. and R. S. W. all acknowledge support from an SRC maintenance grant during some part of the above observations.

Carbon and M-type giant stars in the Magellanic Clouds

THE late M- and C-type giant stars are of special interest in studies of stellar and galactic evolution as they are found at the extreme low temperature limit which stars first reach after evolving away from the main sequence, and also because they show remarkably different galactic distribution. Because of the pronounced strength of absorption bands of molecular oxides and of the carbon and cyanogen molecules in the spectra of these stars, extremely small dispersions can be used. Modern large telescopes equipped with Ritchey-Cretien optics allow relatively large fields to be surveyed to faint limiting magnitudes. Thus stars can be segregated and classified whose distance moduli are 22 mag and more. Now stellar populations can be sampled and surveys made of the distribution of the stars in space in the Magellanic Clouds and in the less obscured regions near the galactic centre. Three such surveys are described here. They indicate that unsuspected differences in the mixture of C and late M giant stars exist in the nuclear bulge of the galaxy and in various regions of the Magellanic Clouds. Such studies also yield new information concerning the intrinsic luminosities of C and M giant stars in these three galactic systems.

Nassau and Van Albada¹ showed in 1949 how red giant stars could be recognised and classified spectroscopically in the near-infrared region with a dispersion of $1,700 \text{ \AA mm}^{-1}$ at the atmospheric A band. Their findings were used to determine the galactic distribution of C- and M-type giants. While these two spectral types show strong concentration towards the galactic equator, the M-giants are found in large numbers toward the galactic nucleus and the C stars towards the anticentre². This suggests that within the galactic nuclear bulge a large concentration of M giants must exist and but few carbon stars.

We have, with Hoag's unpublished data, surveyed the clear nuclear bulge region near the globular cluster

NGC6522 known as Baade's Window. The survey was carried out at the prime focus of the Cerro Tololo Inter-American Observatory's 4-m telescope with the aid of a grating-prism combination of the kind described by Bowen and Vaughan³, and by Hoag⁴. A spectral dispersion of $2,300 \text{ \AA mm}^{-1}$ at the A band was achieved. On hypersensitised Kodak IV-N plates, exposed for 60 min, spectra as faint in the near infrared as $m_1 \text{ mag} = 18.5$ in the photometric system of Kron, Gascoigne and White⁵ were recorded; this limiting magnitude exceeds by three magnitudes the faintest red giant star found in the survey. The M giants found are so numerous that if one counts only stars of type M6 or later, one reaches a surface density of 2,400 stars per deg^2 . By contrast, C stars are virtually non-existent in the galactic bulge since only one such star appeared in the search area whose diameter is 23 arc min.

In the present investigation, the same observational instrumentation and techniques were used to study the distribution of red giant stars in the large and small Magellanic Clouds (LMC and SMC). In the LMC seven sample 0.12 deg^2 areas were investigated. Of these, three are found within the LMC Bar, including one in the optical centre, one in the so-called 'radio' centre which marks the centre of the LMC neutral hydrogen distribution and one in the western sector of the Bar; the remainder are at various outlying points up to 3.5° away from the optical centre in the northern, northeastern, eastern and southern directions. For the positions of the optical and radio centres, the coordinates published by Bok⁶ were used. The SMC centres will be described later.

The LMC survey is an extension to a fainter apparent magnitude of the earlier survey carried out by Blanco and McCarthy⁷, who used a thin objective prism with the Curtis Schmidt telescope at Cerro Tololo to study the distribution of late M giants over an 8.75 deg^2 area of the LMC. The spectroscopic dispersion of $6,700 \text{ \AA mm}^{-1}$ in that study allowed the classification of late M giants into a natural group of stars of about M6.5 and later. In the present survey, it was possible to classify each M star to the nearest half subclass. When stars of type M6.5 and later are segregated they show surface densities that are somewhat higher but still in reasonable agreement with the ones found previously; the differences are probably caused by a different cut-off in spectral types near class M6.5, a problem caused by the extremely small spectroscopic dispersion of the thin-prism survey. As will be discussed later, many C type stars are found in the LMC. These were not detected in the

Table 1 Carbon and late type M Stars in selected regions of the Small and Large Magellanic Clouds and in a central region of the Galaxy

*Photoelectric sequence has been established in this region.

previous survey although, *a posteriori*, it is possible to recognise them on the thin-prism plates and, in fact, a small fraction (less than 5%) of such C stars were erroneously included in the natural group of late type M giants. Again this is not surprising considering the small dispersion used. An important result of the survey described here is that it confirms the main features of the LMC M-giant distribution by surface density and by brightness found by Blanco and McCarthy, namely, the late M giants are more frequently found in the central regions of the LMC than in the peripheral ones and their magnitude distribution shows a well defined frequency maximum at $m_1 = 14.0$ with a dispersion of ± 0.6 mag. In interpreting their result, Blanco and McCarthy assumed that the late M giants in the solar neighbourhood have an absolute visual magnitude of about -1.0 which, with known $(V-I)$ colours, represents a near infrared luminosity $m_1 = -4.6$, similar to that found for the LMC M giants. However, the previous survey made in Baade's Window suggests strongly that the galactic disk late type giants are actually two or more magnitudes fainter than $M_v = -1.0$. Thus there is a marked luminosity difference between M giants in the LMC and in the galactic nuclear bulge. LMC giants of type M seem to be quite comparable to the red giants found in globular clusters in the Galaxy. Although this result is consistent with early theoretical expectations of Hoyle and Schwarzschild⁸, the precise luminosity to be expected of the red M giants in the LMC cannot now be estimated because we lack precise knowledge of metal abundances of late type stars even in the nuclear bulge of our own galaxy. Now we are for the first time detecting the giant branch of late type stars in nearby galaxies. Abundance data must come later from photometric and higher dispersion spectral surveys in the future.

Three SMC sample areas were also included in the current investigation. One is located in the SMC Bar, another in the Wing and the third in an outlying region near the cluster NGC 121. Table 1 shows the results of the present survey for both Magellanic Clouds. By way of comparison our previous results for Baade's Window are also listed. While C stars are extremely rare in the galactic nuclear bulge, they are found frequently in the Magellanic Clouds especially in the central regions. Ordered according to decreasing metallicity, these regions would be as follows: galactic nuclear bulge, LMC, and SMC. Table 1 reflects the same ordering in the ratio of the number of C stars to the number of late M giant stars but in a reversed sense: almost no C stars are seen in the nuclear bulge where late type M giants abound; C stars outnumber M stars about 2 : 1 in the LMC central areas, while in the SMC practically no M stars are found and the C stars are most frequent in occurrence.

From previous knowledge, the peripheral regions of our galaxy could also be included in this ranking somewhere between the nuclear bulge and the LMC. Although this suggests that chemical composition may be an important determinant of the ratio of C to M giants, age differences must also be taken into account. Some C and M type giant stars have been found⁹ in globular clusters in the Clouds but their number is too small to allow one to make reliable correlations with the metal abundances of the parent globular clusters. Improved theoretical knowledge of cool giant stars will be required before these results can be better interpreted. Nevertheless the present study indicates that if having a C type spectrum is but a stage in the evolution of red giants, as suggested by Wallerstein¹⁰, then the galactic bulge M giants, numerous as they are, must all be approximately coeval and have similar masses and chemical compositions.

Near infrared (m_1) photometry of the C stars was done in the present study, using Kodak I-N plates exposed through a Schott RG 695 filter and newly established photoelectric

near-infrared magnitude sequences. The mean m_1 value for the LMC C stars is 14.0 for the field which contains the photoelectric sequence, LMC Bar-west; for the SMC the corresponding value is 14.6 m_1 (in the SMC Wing region which also has a photoelectrically determined magnitude sequence). The difference is that to be expected from the distance moduli of the two Magellanic Clouds. In both clouds, then, the near infrared luminosities for C stars is $M_1 = -4.6$, similar to the M giants as found above. Earlier reliable estimates of the luminosities of C stars are lacking, but Gordon's study¹¹ suggests that no marked difference exists with the luminosity of the carbon stars in the solar neighbourhood.

The frequency of C stars in the central or bar regions of the two clouds is remarkably high, about 600 stars per deg.². This is another indicator that the clouds have had rather different evolutionary histories from the galaxy.

Comparing the Table 1 data for the LMC and SMC late type giants one finds the SMC extremely deficient in late type M giants. Also, stars as late as M9 are found in the direction of the galactic centre, stars as late as M8 are found in the LMC but in the SMC no M star later than M6 has been found. Detailed lists of the stars found in this study including photometric and positional data will be published elsewhere.

Earlier studies of the red giants in the LMC but to a much brighter limiting magnitude were made by Westerlund and coworkers^{12,13}; these did not apparently detect the main features of the distribution of red giants outlined here, although undoubtedly the very brightest of the C stars and the M supergiants were recognised and recorded. More recently Sanduleak and Davis Philip¹⁴ have surveyed the C stars in the SMC with objective prism spectra obtained in the spectral region of the C₂ Swan band using the Curtis Schmidt telescope. The overall distribution found by them seems to be correct but their survey shows only a small fraction of the stars detected in the current investigation. Sanduleak provided us with a list of the positions of his SMC carbon stars so that we could compare results.

We thank the USNSF for the operation of the Cerro Tololo Inter-American Observatory. M.F.M. thanks the Foundation for support during a stay in Chile as visiting scientist at CTIO. We also thank Dr P. J. Treanor, Director of the Vatican Observatory who enabled us to meet and analyse our observations, and finally, Dr A. Hoag, Director of Lowell Observatory, who helped us to develop the observational technique used in this study.

How to locate the electrically conducting fluid core of a planet from external magnetic observations

A NEW method is proposed here for locating the electrically conducting fluid core of a planet from external magnetic observations. When tested with the aid of geomagnetic data, the method gives for the radius of the Earth's liquid metallic core a value which differs insignificantly from the accepted value (based on seismic data). These findings have important implications for future investigations of the magnetic fields and internal structure and dynamics of the Earth, Jupiter, and other magnetic planets.

Consider, as a good first approximation to a real planet in the present context, an isolated spherical planet of radius r_s consisting of an electrically conducting spherical fluid core of conductivity σ and radius r_c surrounded by a non-conducting mantle of thickness $r_s - r_c$. Suppose that the planet is embedded in a non-conducting atmosphere which extends to infinity and that the whole of space $r > 0$ is pervaded by a magnetic field $\mathbf{B}(\mathbf{r}, t)$ due entirely to electric currents of density \mathbf{j} flowing in the conducting core. Any effects due to permanent magnetism are assumed negligible so that the magnetic permeability μ is everywhere equal to that of free space. (Here t denotes time and \mathbf{r} is the vector distance of a general point from the centre of the planet.)

Specifying \mathbf{j} in $0 < r < r_c$ suffices to determine \mathbf{B} throughout the whole of the planet and the surrounding space, but the inverse problem of determining \mathbf{j} in $0 < r < r_c$ from a full description of \mathbf{B} outside the core has no unique solution. Nevertheless, as we shall argue later, measurements at any epoch t of $\mathbf{B}(\mathbf{r}, t)$ and also of its time rate of change $\partial\mathbf{B}/\partial t$ over any closed surface that encloses the planet can be used to determine the radius r_c of the core of the planet in a simple and straightforward way. This is so provided that measurable fluctuations in \mathbf{B} occur on time scales τ that are so short in comparison with the time scales on which effects due to ohmic decay make themselves felt that the fluctuations can, with sufficient accuracy, be ascribed largely to the rearrangement of lines of magnetic force by fluid motions in the core.

The last condition requires that

$$\tau \equiv \overline{B/\partial B/\partial t} < \mu \sigma \alpha^2 r_c^2 \quad (1)$$

where \overline{B} and $\overline{\partial B/\partial t}$ are typical magnitudes of \mathbf{B} and $\partial\mathbf{B}/\partial t$, respectively, and αr_c is a length-scale characteristic of the spatial distribution of \mathbf{j} in $r < r_c$, α being typically ≤ 1 . Over time intervals satisfying equation (1) (which are, of course, very much less than the time scale associated with the generation of the magnetic field by the dynamo process) we can, to a first approximation, treat the core as a perfect electrical conductor, for which it is impossible, by Faraday's law of electromagnetic induction, to change the magnetic flux linkage $N(r = r_c)$ (ref. 1, for further details and references see refs 2 and 3). (Fluctuations in $N(r = r_c)$ when σ is infinite would generate electric currents of infinite strength, requiring an infinitely powerful source of energy.) For any fixed closed (but not necessarily spherical) surface Σ given by $r = R$ which encloses the origin $r = 0$ we can define a quantity $N(t; r = R)$ equal to the total number of intersections of lines of magnetic force with Σ ; thus

$$N(t; r = R) \equiv \iint_{\Sigma} |\mathbf{B} \cdot d\mathbf{A}| \quad (2)$$

$d\mathbf{A}$ denotes the vector element of area of Σ , over the whole of which the area-integral is taken. At the bounding surface of a perfect conductor, N is independent of t , so that $\delta N/\delta t$ vanishes and so do all higher derivatives $\delta^2 N/\delta t^2$ and so on.

The quantity N can be calculated quite simply (in principle) for all surfaces Σ that lie outside the core, as $\mathbf{j} = 0$ in $r > r_c$ and \mathbf{B} in $r > r_c$ can therefore be expressed as the gradient of a scalar V (say) satisfying Laplace's equation $\nabla^2 V = 0$. This property enables \mathbf{B} to be determined everywhere in $r > r_c$ from measurements of \mathbf{B} over any single closed surface in that region, such as the accessible surface of the planet in $r = r_s$ or a closed surface effectively covered by an orbiting satellite carrying a magnetometer. Thus, this new method for determining the radius r_c of the electrically conducting core of a planet from measurements of \mathbf{B} in $r \geq r_s$ involves, in principle, taking such measurements for two epochs $t = t_1$ and $t = t_2$ separated by a time interval $t_2 - t_1$ satisfying the inequality expressed by equation (1), and calculating from these measurements the quantity

$$\Delta N(t_1, t_2; r = r_s - p \Delta r) \equiv N(t_2; r = r_s - p \Delta r) - N(t_1; r = r_s - p \Delta r) \quad (3)$$

at successive levels $r = r_s - p \Delta r$ within the planet, where $p = 0, 1, 2, 3, 4$, and so on, marching downwards from the surface in conveniently short steps of length Δr . In general, ΔN will be non-zero when $p = 0$ (corresponding to the surface of the planet $r = r_s$) and also at successive values of p , if Δr is small enough, until p reaches that value p_c (say), at which ΔN effectively vanishes. The value of r_c is then given by

$$r_c = r_s - p_c \Delta r \quad (4)$$

To avoid ambiguity, it is necessary to find all values of p at which ΔN is equal to zero and then select the correct value of p_c by requiring also that higher time-derivatives of N should vanish.

Further details of the method, including the systematic analysis of the physical and mathematical approximations upon which it is based, and the treatment of errors will be reported elsewhere (R.H., F. J. Lowes & S. R. C. Malin, in preparation). It is enough to remark here that the first practical result based on the new method is encouraging (if it is not fortuitous), for when applied to the Earth, for which $r_s = 6,371$ km, the method gives for r_c a value which differs insignificantly, by less than 2%, from the accepted value $3,486 \pm 5$ based on seismological data. (This calculation was kindly carried out by S. R. C. Malin and colleagues at the Geomagnetism Unit of the Institute of Geological Sciences, NERC, using one of the best available models of the geomagnetic secular variation, where determinations of the main geomagnetic field—namely that field obtained when contributions due to ionospheric and magnetospheric currents have been removed by taking annual mean values of the observations—for the period 1965 to 1975 were fitted by a spherical harmonic series up to and including terms of degree 8.) The method should prove valuable in the investigation of the internal structure of other magnetic planets, such as Jupiter⁴, Saturn and Mercury (for which the sizes of the electrically conducting fluid cores are not yet known), provided that sufficiently detailed measurements of their main magnetic fields and secular changes can be made in future work with space-probes. If the pressure at the level $r = r_c$ in Jupiter is equal to the critical pressure P at which molecular hydrogen changes to its metallic form, which is several megabars and well above the range of operation of high pressure laboratory apparatus, then the determination of r_c by the proposed new method will lead directly to an estimate of P which would serve as a check on estimates⁴ based on shock wave experiments and quantum mechanical calculations. On the other hand, if r_c is so close to r_s that the corresponding pressure at $r = r_c$ is well below present estimates of P (even allowing for the large uncertainties in these estimates, more than a factor of two), then it would be necessary to take seriously the possibility (see refs 4 and 5) that impurities render the molecular hydrogen layer in Jupiter sufficiently conducting to support dynamo action within it.

I thank Dr C. T. Russell for correspondence and a preprint⁷ that prompted the publication of this note.

ULF tree potentials and geomagnetic pulsations

HIGH-SENSITIVITY measurements of ultra-low-frequency (ULF; frequencies less than 5 Hz) geomagnetic pulsations¹ usually require elaborate receiving antennas ranging from large air-cored coils² through multi-turn steel, or mumetal-cored solenoids^{3–5} to small superconducting loops immersed in liquid helium⁶. Pairs of electrodes inserted in the ground have also been used as antennas^{7,8}. The need for a large spacing between the electrodes (varying from hundreds to thousands of metres) and the difficulty of calibrating the measurements absolutely have resulted in the almost universal use of the more compact and easily calibrated coil-type antennas in recent years. I describe here a new method for measuring ULF geomagnetic pulsations, which requires a minimum of elaborate equipment. The method is based on the use of trees, or, more specifically, on the use of pairs of electrodes inserted into trees, as ULF receiving antennas.

There are several reasons that this new method of measurement may be of interest. The equipment is simple and thus the method could lead to more widespread observations of ULF geomagnetic pulsation phenomena. The method of measurement also provides new information about tree potentials, that is, it shows that some, and perhaps all, of the ULF components of these potentials are induced by ULF geomagnetic field fluctuations and do not originate in the trees themselves. Finally, although it is not clear at present what effect induced ULF electric fields may have on the growth and other vital processes in a tree, the link between these ULF electric fields and geomagnetic field fluctuations suggests that some environment-related changes in trees could also be influenced by changes in geomagnetic activity. These changes may have a natural origin (for example, the changes that occur during a solar cycle⁹) or they may be caused by a variety of human activities (by modern d.c.-powered mass transit systems, which can produce large amplitude ULF electromagnetic fields¹⁰).

The ULF measurements reported here were stimulated by the work of Burr on relatively steady-state tree potentials¹¹. Burr recorded these potentials for more than a decade using a pair of specially-designed non-polarisable electrodes inserted in the cambium of an unspecified tree (which was probably a maple). The electrodes were about a metre apart along the long axis of the tree and Burr observed diurnal, 27-d, and seasonal variations, as well as a suggestion of a correlation with sunspot activity, in their potential difference.

Most of Burr's observations were at frequencies far below the frequency range for ULF geomagnetic pulsations. One series of measurement obtained, however, during an electrical storm suggested that ULF variations of tree potentials might occur on occasion. I therefore began a search for variations with frequencies predominantly in the

Pc 1 geomagnetic pulsation range (0.2–5 Hz). These frequencies correspond approximately to the delta regime for human brain waves.

The measurements were made using a large native oak, *Quercus lobata*, that was located near conventional ULF recording equipment at a site on the Stanford University campus. This latter equipment uses 20,000 turn steel-cored solenoids as ULF antennas and it operated continuously throughout the interval during which the tree measurements were made. Thus, simultaneous measurements of ULF geomagnetic pulsations using both conventional loop antennas and a tree 'antenna' were obtained at the one location.

Two steel nails were used as electrodes. Following Burr's configuration, they were inserted about 0.05 m into the tree along the long axis, with a spacing of 0.76 m. The lower electrode was approximately 1 m above the ground, and the two electrodes faced toward the geomagnetic west. Because the tree was not completely vertical, a line joining the two electrodes would have been inclined approximately 20° toward the geomagnetic east. The diameter of the tree midway between the two electrodes was 0.65 m.

A resistance of about 5 k Ω was typically observed between the electrodes, increasing to about 10 k Ω if polarisation was allowed to occur. A d.c. potential difference was also observed that varied from day to day but whose absolute value was usually in the range 10 to 100 mV, with the upper electrode positive. The electrodes were connected to a low-frequency high-gain amplifier through an RC filter ($R=22\text{ M}\Omega$, $C=50\text{ }\mu\text{F}$). The amplifier was usually set for 50 db gain, and its output was filtered (0.02–7 Hz) before being recorded, generally without additional amplification, on a chart record and on analog magnetic tape.

The ULF signals measured by this system were undoubtedly induced in the tree 'antenna' and not in the shielded cabling between the electrodes and the recording system: when the electrodes were disconnected from the tree and connected to an equivalent 5 k Ω resistor, without any other change in the wiring or configuration of the system, only a steady low level of white noise (typical resistor thermal noise) was observed.

Similarities between the ULF signals recorded conventionally and with the tree 'antenna' were immediately apparent on the chart records. More detailed analysis confirmed that Pc 1 pulsation events recorded by the two systems were very nearly identical in all their important characteristics. Figure 1, for example, shows spectrograms of a sequence of four Pc 1 pulsation events that occurred during the interval 1200 to 1500 UT on 17 January 1976, and which were received by the tree 'antenna' (a) and the conventional north-south solenoid antenna (b). With the exception of a lower signal-to-noise ratio for the tree measurements, the two Pc 1 pulsation records are closely alike. It will also be noticed that the lower frequency Pc 2/Pc 3 geomagnetic activity (frequencies in the range 0.02 to 0.2 Hz) is recorded similarly by both systems. The amplitude of the ULF pulsations in the tree potentials is very small. For the Pc 1 pulsations shown in Fig. 1, the maximum amplitude of the potential fluctuations was about 0.1 mV.

The nearly identical occurrence and spectral characteristics of ULF events measured by the tree electrodes and by the conventional ULF equipment indicated that the tree potentials were largely induced by ULF time variations of the geomagnetic field. To investigate this possibility, a portable planar search coil powered by a 1 Hz signal generator was moved around the tree near the electrodes. It was found that a 1 Hz oscillation of the potential difference between the tree electrodes was produced only when the search coil was orientated with its moment vector in the north-south direction. When the two electrodes were moved to the north face of the tree, a response from the electrodes could be obtained only when the search coil moment vector was orientated in the east-west direction.

Fig. 1 Spectrograms of a series of Pc 1 geomagnetic pulsation events recorded at Stanford, California, using tree potentials (a) and a conventional solenoid antenna (b). Short intervals of a 1 Hz calibration signal appear at the start of each hour. The vertical lines in the upper spectrogram are caused either by local electromagnetic transients or by natural sferics; similar lines occur in the lower spectrogram, but they are not as obvious because the background noise is comparatively suppressed.

These results, and the observations of natural Pc 1 pulsations, can possibly be best understood by considering the tree/electrode pair combination to form a collection of conducting loop antennas in which e.m.f.s may be induced by magnetic field fluctuations in the appropriate direction. The conducting paths are provided by the conducting material of the tree (and the cambium in particular¹¹), and, for field fluctuations in a particular direction, the area of the relevant loop antenna is defined by the intersection of the tree with a vertical plane perpendicular to the particular field direction and passing through the two electrodes. Thus, in the measurements reported here, the Pc 1 pulsation events observed in the tree potentials were produced by Pc 1 pulsations of the north-south component of the geomagnetic field.

Further tests showed that the tree potentials could only be detected in a living tree. Thus, when a tree dies, the potentials gradually disappear as the wood dries and loses its conductivity.

In conclusion, measurements with tree electrodes show that trees may be used as 'antennas' to detect ULF geomagnetic pulsations. The measurements also show that ULF tree potentials are largely produced by ULF fluctuations of the geomagnetic field (the remaining component of the potentials is probably thermal noise). Presman¹² noted that electromagnetic fields usually have an adverse effect on living processes. If the ULF geomagnetic pulsations have any adverse effect on the growth of trees (and, as we have seen, they must induce electric currents in the living material) these effects could possibly be observed in tree ring data. Pc 1 geomagnetic pulsation occurrences vary markedly over a solar cycle⁹ and thus, if these particular pulsations affect tree growth, a solar cycle in tree ring data could occur. LaMarche and Fritts¹³ searched unsuccessfully for a relation between tree ring data and sunspot numbers. The phase of the Pc 1 pulsation solar cycle, however, differs by several years from the sunspot cycle and, assuming the two cycles affect tree ring data, they may tend to obscure each other's effects. Furthermore, other geomagnetic pulsations and higher-frequency electromagnetic signals have their own cycles of occurrence, and their effects on tree ring formation, if any, could add further to the complexity of the tree ring data. Studies of these possible effects are desirable, because the tree ring data could provide a unique

record of past ULF and higher-frequency geomagnetic activity.

Mass spectrometric measurement of the positive ion composition in the stratosphere

THE ion composition of the upper atmosphere has been the subject of many experiments. Early mass spectrometer measurements have been primarily concerned with the ion composition at altitudes between 60 and 250 km (refs 1-6). Few data, however, are available on the charged particle composition of the stratosphere. Global ion density measurements using electric probes⁷⁻¹¹ indicate number densities of the order of 100-10,000 cm⁻³ for positive ions in this region. Arnold *et al.*¹² have recently published the first mass spectrometric data of the stratospheric ion composition, obtained on the downleg portion of three rocket flights. Above 40 km they observe the proton hydrates as being the most abundant ions. Below 40 km a change in the predominant ion species is seen, which is explained by Arnold *et al.* by ion molecule reactions between water cluster ions and

formaldehyde. One of the possible dangers, inherent to rocket flights, however, is the alteration of the ion composition, due to shock wave-induced fragmentation. Mass spectrometric measurements on this region using a balloon-borne instrument were suggested¹³ as early as 1969. Here we give the first preliminary results of a successful flight, performed with a balloon-borne quadrupole mass spectrometer on 30 September 1977. A 100,000 m³ Zodiac balloon was flown at mid-latitude (CNES launching site at Aire sur l'Adour, France, 44°N) at 18.27 UT and reached the altitude of 35 km at 20.00 UT. The measurements were started at 20.14 UT, which is after sunset.

The gondola, which will be described in more detail elsewhere, primarily consists of a high-speed helium cryopump, in which is built a quadrupole mass filter, followed by a high gain electron multiplier. The ions were sampled through a 0.2 mm hole in a 0.1 mm thickness stainless steel flange, which can be biased with respect to the gondola structure. Signal detection is realised

Fig. 1 Observed count rate versus mass number measured at 35 km altitude. Both *a* and *b* have been obtained by averaging of the counts observed, during seven scans. The applied draw-in-potential was -13 V.

by both analogue and pulse counting techniques. The mass spectrometer covers the mass range from 0 to 109 AMU. Measuring in mass domains as well as sweeping the complete mass range is possible¹⁴. Sweeping the complete mass range was realised by using discrete steps approximately 1 AMU in size. The integration time for pulse counting was 6 s per step. Thus spectra were obtained in the form of a histogram, as is shown in Figs 1 and 2. A fixed resolution mode was used throughout all scans reported here. Two separate draw-in-potentials were used, -13 and -4.6 V. Figure 1 represents the results obtained at -13 V and Fig. 2 those at -4.6 V. It should be noted that in both figures the number of observed counts per second for masses smaller than 55 AMU have been represented with a different scale factor. The count rate due to noise pulses was smaller than 0.1 s^{-1} during the whole flight.

The mass numbers of the detected ions are listed in Table 1, with the draw-in-potentials and the uncertainty in atomic mass numbers. Counts below mass 10 have not been taken into account, because instabilities have been observed in the power supply of the quadrupole for such low mass values.

As can be seen from Table 1, the uncertainty for lower mass numbers is rather high for two reasons. First, the fixed resolution, chosen rather low in favour of high sensitivity, gives rise to much more broadened peaks at lower masses, than at higher ones. Second, due to the low counting rate at low mass numbers, it was impossible to build up a complete histogram even after several scans and thus a faulty conclusion may be drawn about

Fig. 2 Observed count rate versus mass number at 35 km altitude. *a*, The result of five scans; *b*, two scans. Applied draw-in-potential was -4.6 V.

the exact position of the pass peaks. Above mass 50, however, the signal was strong enough to permit a higher degree of certainty. Furthermore, the mass domain from 50 to 109 AMU has been scanned with a higher resolution and the results confirm those of Table 1. Masses $19 (18 \pm 3)$ and 20 ± 3 , 37, 55, 73 and 109 can be identified with the cluster ions $\text{H}^+(\text{H}_2\text{O})_n$, n ranging from 1 to 6.

In all spectra, mass 73 was the most abundant peak among the water cluster ion peaks. The observed distribution of the $\text{H}^+(\text{H}_2\text{O})_n$ cluster ion peaks is represented in Table 2.

Table 2 does not represent a correct number density distribution of the hydrated hydronium ions, as a correction factor has to be taken into account to convert peak height to number density (even on relative scale). The result of this correction, which is not known exactly and which cancels the effect of lower transmission of the mass filter at higher mass numbers, will be a larger percentage of mass 91. As possible cluster breaking up due to electric fields must also be considered, our results are difficult to compare with the distribution calculated by Mohnen¹⁵.

It is not completely clear why the distribution of $\text{H}^+(\text{H}_2\text{O})_n$ is different at different draw-in-potentials, although again electric field-induced breaking up of the cluster ions may have an important role.

Apart from the water cluster ions, which are expected according to the known reaction schemes¹⁶, additional peaks

have been observed, among which 96 ± 2 was the most abundant. At low draw-in-potentials, this peak was even larger than the one at mass 73. Masses 29, 42, 60 and 80 have also been observed by Arnold *et al.*¹², but they do not mention mass 96 ± 2 , nor do they report that they have observed masses 73, 91 and 109. Because this (96 ± 2) is the most abundant mass peak among the non-proton hydrates which we have observed, it is tempting to conclude that rocket-borne measuring devices are more disturbing than balloon-borne instruments. However, care must be taken, as the ion-molecule reaction channels might be different during night time. The observed mass peaks can be partly fitted into the formaldehyde ion chemistry if 47 ± 3 and 50 ± 3 are tentatively identified as $H^+(CH_2O)H_2O$ and 96 ± 2 as $H^+(CH_2O)_2(H_2O)_2$ or $C_2H_2O^+(H_2O)_3$. But, one should be careful because although the existence of formaldehyde in the stratosphere has been predicted theoretically¹⁷, to our knowledge no experimental observation of it has been published. Furthermore, no reaction rate constants of formaldehyde ions or molecules with proton hydrates have been published. Thus any tentative identification must be regarded as speculative. As an alternative interpretation, however, mass numbers 60, 78 and 96 can be tentatively assigned to the hydrates of N_3^+ , namely $N_3^+(H_2O)$, $N_3(H_2O)_2$ and $N_3^+(H_2O)_3$, respectively, which have already been observed in laboratory air flow discharges by Hayhurst and Padley¹⁸. In view of this, 47 ± 3 and 50 ± 3 may be interpreted as due to O_3^+ .

We need more data, especially higher resolution mass spectra and conclusive laboratory work, before any final conclusions can be made. It is clear, however, from the observations reported here and from those of Arnold¹², that apart from the hydrated hydronium ions some other unknown ionic species are present in the stratosphere. This should give a new motivation for more extended laboratory and *in situ* investigations on the ionic chemistry of the stratosphere.

Chemical interpretation of Viking Lander 1 life detection experiment

PRELIMINARY results of the Viking Lander 1 (VL-1) biology experiments¹ revealed that humidification of the martian soil sample in the gas exchange experiment (GEX) released substantial amounts of carbon dioxide and oxygen, as well as detectable amounts of nitrogen and argon or carbon monoxide. We have reviewed the available flight data and found that, when the amounts of evolved gases were plotted in an adsorption potential plot, the amount of evolved oxygen was anomalously high compared to the other gases. This paper also describes simulation experiments with a model Mars soil provided by the Viking Inorganic Analysis Team (ICAT) and treated with a radiofrequency (RF) glow discharge in a simulated martian atmosphere. The findings indicated that the GEX simulation procedure released oxygen, carbon dioxide, and nitrogen in amounts comparable to that seen in the experiment on Mars.

The design of the GEX and its modes of operation have been described elsewhere². The values first reported¹ have been revised, and the maximum amounts of gases evolved from the entire 1 cm³ of humidified sample in the test cell have been given by Oyama *et al.*³ as 83 nmol N₂, 775 nmol O₂, 9,800 nmol CO₂, and 13 nmol Ar/CO. Ar and CO were not separated in the chromatographic column.

The postulate considered here for the gas evolved in the VL-1 humid mode GEX was that the amount of gas seen could have been physically or chemically adsorbed, or attached in a surface complex, on the martian soil. Using a molecular area of 14.6×10^{-20} m² for O₂ and an estimated bulk density of soil sample of 1.3 g cm⁻³, it can be calculated that the evolved O₂ would cover an area of 0.052 m² g⁻¹ soil. The estimated bulk density was the same value as that used in ref. 3 and was the midpoint of the range estimated in ref. 4 from the observed physical behaviour of the fine-grained materials in the immediate vicinity of VL-1. A similar calculation for the CO₂, using a molecular area of 17×10^{-20} m², gives a surface coverage 0.77 m² g⁻¹. A specific surface area of 1 m² g⁻¹ or greater could, therefore, have accommodated the evolved O₂ and CO₂.

Fig. 1 Adsorption potential plot of gas evolved in VL-1 GEX humid mode experiment. The 'A value' ordinate includes sample temperature, T , in K, molar volume of liquid adsorbate, V_m , in cm³ g⁻¹, and the reciprocal of the relative vapour pressure of the adsorbate, P_0/P where $A = (T/V_m) \log_{10} (P_0/P)$. \diamond , CO; \circ , O₂; \square , CO₂; \triangle , N₂; ∇ , Ar.

Fig. 2 Gas released in the humid mode from the VL-1 GEX (solid line) and from RF glow discharge treated Amboy no. 6 soil (dashed line). RF glow discharge conditions were 33 mm³ STP s⁻¹ O₂ flow, 0.50 mm Hg = 66 Pa O₂ pressure, 50 W RF power at 13.56 MHz, 398 K sample temperature, and 18 h = 65 ks treatment time (d × 86.4 = ks) ●, ○, O₂; ■, □, CO₂; ▲, △, N₂.

Data for the gas composition of the martian atmosphere⁵ and the equilibrium vapour pressures of the pure gases⁶ were used to calculate the relative pressure, P/P_0 , of the gases in the martian atmosphere at a soil acquisition temperature of 190 K (ref. 7). An adsorption potential plot, similar to that used for the prediction of adsorption of trace gas species in spacecraft contaminant control systems⁸, is shown in Fig. 1. The CO₂, N₂, CO, and Ar points approximate a straight line, but the O₂ point is anomalously high. An adsorbed monolayer volume was derived from the potential plot by extending the straight line to the 'A value' range for physical adsorption of nitrogen at the temperature of boiling liquid nitrogen, and plotting the extrapolated adsorption data as a BET plot. A surface area of 17 m² g⁻¹ was calculated for the martian soil, from a nitrogen molecular area of 16.2 × 10⁻²⁰ m².

A simulated martian soil, Amboy no. 6, had been obtained by ICAT from the Amboy volcanic crater in southern California. It was chosen as a simulated martian soil because of its low organic and high iron content. More recently, synthetic mineral mixtures have been made-up as model martian soils, but it is believed that differences between the Amboy soil and later synthetic models would not be consequential to studies described here. The Amboy no. 6 soil sample was first mixed with 0.01% calcium superoxide to test sample handling and analytical techniques for the GEX simulation. The superoxide and soil were mixed to provide a suitable mass of sample for handling in the simulation apparatus, and the amount of superoxide alone was in the microgram range. The model soil had been ground, sieved, and remixed and its BET surface area was 22 m² g⁻¹. The oven-dried (423 K) sample was subjected to a humid atmosphere in the GEX simulation apparatus and released 1,820 nmol O₂, which was 5% more than calculated from reaction stoichiometry.

Because the sample handling and analytical techniques of the GEX simulation seemed adequate to test the release of small quantities of oxygen in a humid atmosphere, the release of oxygen from labile oxygen-containing surface complexes was tested next. A 1 g sample of Amboy no. 6 soil was pretreated to remove adsorbed water and equilibrated with a simulated martian atmosphere. The simulated martian atmosphere was

made and analysed by Matheson Gas, as 2.50 volume % N₂, 0.33 volume % O₂, 95.66 volume % CO₂, 1.35 volume % Ar, and 0.15 volume % CO. The moisture content of the mixture was 48 p.p.m. The Amboy no. 6 soil sample was subjected to a RF glow discharge in conditions chosen to expose the sample to active oxygen species at a high enough concentration level to accelerate the kinds of reactions possible between a soil and the naturally occurring active oxygen species at the surface of Mars⁹. A control sample was carried through the same time, temperature, and oxygen flow regime in the reactor, but without the RF field.

Figure 2 shows results obtained from the GEX humid mode simulation, and comparable results from VL-1 GEX humid mode data. The relative amounts of evolved gas species and their rates of evolution were similar for the GEX data and the simulation experiment, suggesting that the GEX oxygen release could have been the consequence of the long time of interaction of the martian soil with reactive oxygen species produced in the atmosphere by ultraviolet radiation.

The treatment of the VL-1 GEX humid mode data, together with the results of the simulation experiment, leads to several conclusions. First, the quantities of gases released at the temperature and humidity conditions of the GEX test cell were in agreement with a model of physical adsorption from the martian atmosphere on a soil of 17 m² g⁻¹ surface area, except for the anomalously large quantity of oxygen—which must be accounted for by oxygen adsorption in strongly bound or chemisorbed states, or as active oxygen compounds (for example, peroxide, superoxide, hydroperoxide) that decompose in a humid atmosphere.

Second, the results of the simulation of the GEX humid mode with RF glow discharge treated soil supports the possibility that the oxygen release seen in the GEX arose from labile oxygen surface species formed during long exposure of the martian soil to ultraviolet radiation induced active species in the atmosphere.

Energy basis of dielectric relaxation loss

JONSCHER has reviewed the phenomenology of dielectric, mechanical and some magnetic relaxations in a very wide range of materials¹. He found² that a fundamental insight into the physics of such processes may be obtained by considering that the ratio of the energy dissipated to the energy stored in these materials per radian of sinusoidal excitation is a constant which does not change over a very wide range of frequency.

This observation, the so-called 'universal dielectric response', has been derived by examining the behaviour of dielectric loss in the frequency and time domains, and tentatively modelled in terms of a partial screening mechanism²⁻⁴. Here we shall discuss Jonscher's work within the context of earlier work, and it will be shown that the presence of a loss peak in the frequency domain, or a change in the slope of the double logarithmic time-domain graph, need not require the two consecutive processes in the material that have been thought to be necessary^{1,4}. Subsequently, the clarified 'universal dielectric response' is used to interpret various empirical loci on the complex permittivity plane, Cole-Cole⁵, Davidson-Cole⁶ and Williams-Watts⁷⁻⁹ plots, and to compare these loci with the simple Debye form in terms of the behaviour of a single 'storage parameter', s , replacing Jonscher's n and m and the previously physically uninterpreted α of Cole and Cole and β of Davidson and Cole.

The classical Debye theory of dielectric relaxation¹⁰ involves the orientation of polar molecules in an applied field being resisted by the viscous damping of this rotation, as the molecules are considered as spheres in a continuous medium having the macroscopic viscosity of the material. On the complex relative permittivity plane

$$D^*(\omega)/\epsilon_0 E = \epsilon^*(\omega) = \epsilon'(\omega) - i\epsilon''(\omega) = 1 + \chi^*(\omega) \quad (1)$$

where ϵ_0 is the permittivity of free space, $8.845 \times 10^{-12} \text{ F m}^{-1}$, and $\chi^*(\omega) = \chi'(\omega) - i\chi''(\omega)$ is the susceptibility, the locus of ω predicted by the Debye theory is semicircular, with

$$\epsilon^*(\omega) - \epsilon_\infty = (\epsilon_s - \epsilon_\infty)/(1 + i\omega\tau) \\ = (\epsilon_s - \epsilon_\infty)/(1 + \omega^2\tau^2) - i(\epsilon_s - \epsilon_\infty)\omega\tau/(1 + \omega^2\tau^2) \quad (2)$$

In 1941 Cole and Cole⁵ noted that the dispersive mechanisms then used to explain dielectric relaxation loss, namely this Debye viscous damping or alternatively direct current conductivity, had the common characteristic of being wholly dissipative in nature, and that this was represented in the equivalent circuit of the dielectric by a pure resistance (Fig. 1a). However, they also showed that the behaviour of a very large number of dielectrics produced not a semicircle on $\epsilon^*(\omega)$, but a minor arc of a circle having its centre 'below' the real axis, described by

$$\epsilon^*(\omega) - \epsilon_\infty = \frac{(\epsilon_s - \epsilon_\infty)}{1 + (i\omega\tau)^{1-\alpha}} \quad (3)$$

and requiring that the dispersive mechanism producing the loss should not be represented by the purely dissipative Debye resistor, but rather by a complex 'polarisation impedance' $R(i\omega\tau)^{-s}$, Fig. 1b. The loss peak produced in consequence by the Cole-Cole equivalent circuit is described by

$$\epsilon''(\omega) = \chi''(\omega) = \frac{(\epsilon_s - \epsilon_\infty) [\cos(\alpha\pi/2) (\omega\tau)^{1-\alpha}]}{1 + 2 \sin(\alpha\pi/2) (\omega\tau)^{1-\alpha} + (\omega\tau)^{2(1-\alpha)}} \quad (4)$$

which can be compared with the Debye term in equation (2). Both loss peaks are illustrated in Fig. 2.

In the words of Cole and Cole⁵, using the polarisation impedance "implies a conservation or 'storage' of energy in addition to dissipation of energy in the mechanism of molecular interaction responsible for the dispersion". As the vacuum response of the material is accounted for within the small parallel capacitive branch of the equivalent circuit, when

Fig. 1 Equivalent circuits of dielectric relaxation processes: a, Debye; b, Cole-Cole: s is a constant, α ; general: s may be a function of $(\omega\tau)$.

considering the properties of the boxed element in isolation we may write that the dispersive mechanism has

$$\epsilon_0 \epsilon'_b = \epsilon_0 \chi'_b = \epsilon_0 (\epsilon_s - \epsilon_\infty) \sin(\pi/2) (\omega\tau)^{s-1} \quad (5)$$

$$\epsilon_0 \epsilon''_b = \epsilon_0 \chi''_b = \epsilon_0 (\epsilon_s - \epsilon_\infty) \cos(\pi/2) (\omega\tau)^{s-1}$$

$$\text{and hence } \epsilon''_b/\epsilon'_b = \chi''_b/\chi'_b = \cotan(\pi/2) \quad (6)$$

where s is a storage parameter equal in the Cole-Cole dielectric to a constant value, α . Consequently Cole and Cole⁵ concluded that "the ratio of the average energy stored to the average energy dissipated per cycle in the form of heat is a constant independent of frequency". This principle leads to a constant phase-angle, $(-\pi/2)$ in the case of the polarisation impedance, as was first realised according to Cole¹¹ by Irving Wolff in the late 1920s. It also follows^{10,12} from the pioneering nineteenth century time-domain investigations of dielectric loss by Hopkinson, who produced evidence of power-law decay corresponding to parts of Fig. 3, as did Kohlrausch less completely in 1854.

Fig. 2 Frequency domain: the symbols show the slopes of the lines to which the loss peaks are asymptotic. The peaks are vertically separated for clarity. a, Debye; b, Cole-Cole; c, Jonscher; d, general.

Jonscher has discussed the principle in terms of Hilbert transforms¹³, calling it the 'universal dielectric response'¹. He has made^{2,3} the useful extension

$$\varepsilon''_b/\varepsilon'_b = \chi''_b/\chi'_b = (1-p)/p = \cotan(s\pi/2) \quad (7)$$

where p is the proportion of energy stored during a cycle of the field. However, the storage of a constant proportion of energy during each cycle of the field probably results from the storing of a constant proportion of energy during each of the operations of the dispersive mechanism that can take place before the field-reversal at the end of a half-cycle of the applied frequency. It is, therefore, more fundamental to consider each operation of the dispersive mechanism itself. If during this operation a proportion p of the energy is stored (Fig. 4), then equation (7) follows. Of course, if all the energy is dissipated, then the Cole-Cole α is zero, as the polarisation impedance reverts to the Debye resistor when p and s go to zero (cf. ref. 3). The Debye case (Fig. 2a) is the limit of zero energy storage within

Fig. 3 Time domain: the symbols again show the slopes of the lines to which the curves are asymptotic. The non-Debye curves are vertically displaced for clarity. a, Debye; b, Cole-Cole; c, Jonscher; d, general.

the dispersive mechanism. However, unlike the situation in the viscous rotation of the Debye dipole sphere, in most real systems the necessary work will probably be used to separate the moving charge (for example, a pinned dipole^{2,3}) from its counter-charge atmosphere of partial screening, as described by polaron theory^{14,15}, and there will therefore also be some stored energy involved in the system due to the polaronic nature of the moving charge carrier. Although a theoretical investigation of the time course of the local amount of such stored energy might be somewhat difficult, the constant ratio of equation (7) follows

Fig. 4 Schematic diagram of the inferred progress with time of energy storage within an operation of the dispersive mechanism.

when there is inevitably involved, during each dipole jump and operation of the dispersive mechanism, a certain amount of energy storage associated with a certain amount of energy dissipation, and the field has, of course, to supply both. A change in the frequency of the field may affect the numbers jumping, but not the proportionality between the requisite dissipation and storage of energy related to these jumps. If no energy is stored and all is dissipated, we revert to the Debye case, Fig. 2a.

A single and unchanging proportion of storage p corresponding to a single value of s ($= \alpha$) can therefore lead to a definite (and broadened) loss peak, Fig. 2b, without involving two different and consecutive relaxation processes^{1,4}, which thus removes the only apparent enigma hindering the progress of a Jonscher-type interpretation of relaxation loss. The associated change in the exponent of the power-law loss with frequency, equation (4) and Fig. 2b, is both empirically necessary and theoretically acceptable: the Cole-Cole equation (3) has been shown⁵ to obey the Kramers-Kronig relations, modelling the entire necessary equivalent circuit (Fig. 1b) rather than just the polarisation impedance of the particular Hilbert transform demonstration of Jonscher¹³.

In the time domain Cole and Cole¹² further showed that to have not only a finite initial charge as elapsed time t tends to zero, but also a finite total charge transfer as t tends to infinity, the power-law decay of current resulting from step-potential stimulation has to have a knee (Fig. 3). As this occurs for a single value of energy storage p corresponding to a single value of s ($= \alpha$) across the time range, and applies also in the Debye case of $p = s = 0$, again there is no need to postulate two consecutive processes⁴ as, of course, is required to agree with the frequency domain simplification, the loss peak in the frequency domain corresponding to the knee in the time domain.

The asymptotic slopes of the knee, however, are not always those to be expected from the Cole-Cole theory¹ (unless Jonscher's $(n-1)$ equals his m)³. This discrepancy is confirmed by much experimental data^{3,7-9}, and is extremely important as the inference is that p cannot be assumed to be constant in all cases across an arbitrarily wide range of time compared with the time constant τ of the relaxation mechanism. The initial proportion p_i (Fig. 4) and the 'final' proportion p_f correspond through equation (7) with values s_i and s_f of the storage parameter s that are manifested in the time domain as the general slopes of Fig. 3, and in the frequency domain as the asymmetrically broadened loss peak Fig. 2d. This concept will be elaborated quantitatively elsewhere¹⁶, and the required form of decay of p shown to be reasonable.

Meanwhile, let us briefly and qualitatively compare events in the time domain with their results on the permittivity plane, taking t as the reciprocal of the applied frequency $\omega/2\pi$ and assuming the absence of d.c. conductivity, which would mask the dielectric relaxation behaviour. Then if p decays to zero

extremely quickly, before even the time corresponding to t/τ very small ($\omega\tau$ very large), we find Debye results, a semicircle, on $\epsilon^*(\omega)$. If at least p decays to zero by the time corresponding to t/τ very large ($\omega\tau$ very small), then we find Davidson–Cole⁶ results on $\epsilon^*(\omega)$; the Davidson–Cole parameter β will be interpreted elsewhere¹⁶. But if p has not fully decayed to zero by this time corresponding to t/τ very large ($\omega\tau$ very small) we see something like Williams–Watts^{7–9} behaviour on $\epsilon^*(\omega)$, and if p does not decay at all from its initial value by the time that t/τ is very large, then Cole–Cole behaviour is seen on $\epsilon^*(\omega)$. Such effects can either be deduced intuitively by comparing Fig. 2 of ref. 12, with those given here, or derived analytically¹⁶. Thus combining the work of Cole and Cole with Jonscher's effective demonstration of the inconstancy of their parameter α , qualitatively explains all the experimentally observed types of dielectric relaxation. Quantitative results can be expected to advance with polaron theory.

Pressure retardation of vitrinite diagenesis, offshore north-west Europe

PHYSICO-CHEMICAL processes that increase coal rank also increase vitrinite reflectance, or the level of vitrinite diagenesis. The principal physical factors controlling these processes have been identified as geothermal gradient, thermal conductivity of lithological section, duration of heating, and pressure^{1,2}. Interaction of these factors on coalification has not been demonstrated conclusively in nature or by laboratory experiments, but temperature and time have been generally regarded³ as most influential. Although the retarding effect of pressure has been widely recognised, the role of pressure is not clearly understood and has been considered³ negligible. Here the same values of mean vitrinite reflectance in oil ($R_{mo}\%$) have been related to present temperature, (T), and to a function of the present temperature and the ratio of the gradients of normal hydrostatic pressure (P_{NH}) and observed pore pressure (P_p), $T(\gamma P_{NH}/\gamma P_p)$, in Fig. 1a and b respectively. Comparison of correlation coefficients of Fig. 1a and b demonstrates that, for values of R_{mo} less than 1.50%, retardation of vitrinite diagenesis by abnormally high formation pressure, is both significant and predictable. As a corollary, the time factor seems to be of limited significance on a geological scale.

For Fig. 1a and b, values of vitrinite reflectance have been restricted to those from coals and non-calcareous shales from several wells offshore from north-west Europe. Sections sampled in these wells do not show evidence of uplift. The samples range in age from mid-Tertiary to Carboniferous. The wide range of ages might not be considered ideal. It is more important, however that present depths of burial and present temperatures are likely to be the maximum suffered by the samples.

The three types of pressure distinguished in geological sections, pore pressure (P_p), effective overburden pressure

(P_{EO}), and geostatic pressure (P_G), are related according to the simple formula

$$P_G = P_p + P_{EO} \quad (1)$$

Following Gretener⁴, geostatic pressure gradient (γP_G) is taken to be 1.00 psi ft⁻¹ (= 0.231 kg cm⁻² m⁻¹). In offshore north-west Europe, the pore pressure gradient of normally pressured sequences, normal hydrostatic pressure, (γP_{NH}) is generally about 0.45 psi ft⁻¹, and gradient of effective overburden pressure (γP_{EO}) is, therefore, 0.55 psi ft⁻¹. Some samples for vitrinite reflectance have come from normally pressured sequences but others are from abnormal, overpressured intervals. In these intervals, γP_p exceeds γP_{NH} , and is generally greater than 0.50 psi ft⁻¹. Conversely, γP_{EO} in the overpressured intervals is less than 0.50 psi ft⁻¹.

Many techniques for estimating formation pressures are available^{5,6}. Formation tests yield the best pressure information, but not enough have been conducted in the wells studied for composition of a satisfactory pressure profile. Therefore, profiles of sonic transit times in shales (Δt_s) penetrated in the wells have been favoured in this study for estimation of formation pressures^{6–8}. Estimates of pressure by means of this technique, provide sufficient values of pressure for plotting pressure profiles of high precision in individual wells.

Values of present temperature (T), in °F, were estimated by interpolation between control temperatures. Horner-type plots of log recorded, bottom hole temperatures⁹ were used to determine control temperatures. During normal compaction of porous, water saturated shales, geostatic pressure increases as depth of burial increases. Decrease in shale porosity and consequent reduction in pore water content relate to increase in geostatic pressure and effective overburden pressure^{10,11}.

Figure 2, based on data from Lewis and Rose¹¹, shows that the coefficient of thermal conductivity of water saturated, porous shale increases with decrease in water content according to the formula:

$$K_t = (K_s K_r \phi / K_s) \quad (2)$$

where K_t is thermal conductivity of total shale; K_s is thermal conductivity of solid shale (= 1.138 Btu h⁻¹ ft⁻¹ °F⁻¹), K_r is thermal conductivity of fluid (water = 0.363 Btu h⁻¹ ft⁻¹ °F⁻¹), and ϕ is shale porosity (where 1 Btu h⁻¹ ft⁻¹ °F⁻¹ = 1.488 kg cal h⁻¹ m⁻¹ °C⁻¹). It is important that thermal conductivity of water does not change significantly with variations in salinity⁶.

In overpressured section, shale porosity (ϕ), effective overburden pressure, and pore-water content are the same as at shallower depths in normally compacted shale sequences. Thus thermal conductivity will be abnormally low in overpressured sequences, whatever the depth, pressures, and porosity of the overpressured shale-water system.

Reduction in thermal conductivity of overpressured shales causes increase in thermal gradient of the overpressured sequence, according to the equation for heat flow¹¹

$$Q = (k_t/L) a \Delta T \quad (3)$$

where k_t is thermal conductivity of shale section, 'L' is thickness of shale section, and ΔT is temperature change along section of thickness 'L', that is the thermal gradient.

Overpressured shale is a heat insulator and normally pressured shale is a heat conductor¹¹. In a state of thermal equilibrium, however, heat flow in an overpressured sequence (Q_{op}) equals that in normally pressured sequence (Q_{np}) of the same section. For this condition the equation for thermal gradient of the overpressured section (ΔT_{op}) is

$$\Delta T_{op} = (\Delta T_{np} (k_{np}/k_{op})) \quad (4)$$

Therefore, the thermal gradient in the overpressured section will be greater than that of the normally pressured section.

Fig. 1 a, Relationship of vitrinite reflectance ($R_{mo}\%$) to present temperature (T). Temperature in $^{\circ}\text{F}$. Correlation coefficient (r) is 0.716 for the equation $\log_n T = 1.998 + 0.326 R_{mo}\%$. b, Relationship of vitrinite reflectance ($R_{mo}\%$) to the pressure-temperature function ($T(\gamma P_{NH}/\gamma P_P)$). Correlation coefficient (r) is 0.952 for the equation $\log_n (T(\gamma P_{NH}/\gamma P_P)) = 1.838 + 0.433 R_{mo}\%$.

In a subsurface section, the temperature (T_d) at a given depth (D) is determined from the equation

$$T_d = T_s + D \Delta T \quad (5)$$

where T_s is the mean surface temperature. Hence, the temperature at a given depth in an overpressured interval will be greater than the temperature at the same depth in a normally pressured interval for the same type of lithology. Conversely, for a given temperature, heat flow will be lower in an overpressured interval than a normally pressured interval.

The low correlation coefficient ($r = 0.716$) of the relationship of $R_{mo}\%$ to present temperature (T) of Fig. 1a contrasts with the high order of correlation ($r = 0.952$) of the relationship $R_{mo}\%$ to $T(\gamma P_{NH}/\gamma P_P)$ of Fig. 1b. The improved correlation coefficient for the function $T(\gamma P_{NH}/\gamma P_P)$ demonstrates that the influence of abnormal formation pressure must be considered when evaluating the relationship of vitrinite reflectance to natural, subsurface physical conditions.

Coalification has been regarded as a first-order reaction³; the same is probably true of vitrification. In this case, improvement in correlation noted above can be explained readily by reference to the Arrhenius equation

$$k = A \exp(-E/RT) \quad (6)$$

where k is the reaction rate; A is the Arrhenius factor; and $\exp(-E/RT)$ is the Boltzmann factor (= fraction of molecules with energy equal to or greater than the critical activation energy E). From this equation

$$\log_n k = -E/RT + \log_n A \quad (7)$$

where $\log_n A$ is a constant.

By substituting in equation (7) for temperatures T_n (normally pressured) and T_o (overpressured), reaction rates k_n and k_o , at temperatures T_n and T_o , respectively, can be compared according to the formula

$$\log_n (k_o/k_n) = \frac{E}{R} \left(\frac{1}{T_n} - \frac{1}{T_o} \right) \quad (8)$$

where temperatures are expressed in K.

For coeval and identical values of $R_{mo}\%$, one at normal pressure, the other in an overpressured sequence, the tempera-

ture will be higher in the overpressured sequence and (k_o/k_n) will equal 1. However, values of T_n ($\gamma P_{NH}/\gamma P_P$) and T_o ($\gamma P_{NH}/\gamma P_P$) will be the same where T_n and T_o are expressed in $^{\circ}\text{F}$ or in K. This is because ($\gamma P_{NH}/\gamma P_P$)=1 in a normally pressured sequence and ($\gamma P_{NH}/\gamma P_P$)<1 in an overpressured sequence. Therefore from equation 8:

$$\log_n (1.0) = \frac{E}{R} \left(\frac{1}{T_n} \cdot \frac{\gamma P_{Pn}}{\gamma P_{NH}} - \frac{1}{T_n} \cdot \frac{\gamma P_{Pn}}{\gamma P_{NH}} \right) = 0$$

here $T(\gamma P_{NH}/\gamma P_P)$ should be expressed in K.

In Fig. 1b the scatter of points in the gelification stage might indicate a change in the gradient of increase of $R_{mo}\%$. But there are too few points to establish that the rate of increase in $R_{mo}\%$ in the gelification stage is different to that of the vitrification stage, even though physico-chemical processes are different between these stages. In the gelification stage the role of pressure is probably greater than it is in vitrification.

Detailed investigation of the relationship of effective overburden pressure to vitrinite reflectance is still in progress, but

Fig. 2 Relationship of shale water content to thermal conductivity of shale. Increase in thermal conductivity of shale is exponentially related to decrease in water content. Thermal conductivities of 0.724 and 0.905 $\text{Btu h}^{-1} \text{ft}^{-1} \text{ } ^{\circ}\text{F}^{-1}$ relate respectively to shale water contents of 40% and 20%.

preliminary results indicate a closer correlation to $R_{mo}\%$ than that of $T(\gamma P_{NH}/\gamma P_P)$. This may be due to more accurate measure of heating as P_{EO} measures confining pressure, reproducible in closed system laboratory studies. Effective overburden pressure can be determined at the levels of the sample taken for measurement of vitrinite reflectance.

The high coefficient of correlation of Fig. 1b has demonstrated that the combined effect of heat and pressure, especially overpressure, influences increase in vitrinite reflectance for values of R_{mo} less than 1.50%. Pressure has a determinative role in this combination, because of its influence on thermal conductivity of the geological section containing the vitrinite.

Figure 2 and equation (3) indicate that the thermal conductivity of shale in a thick continuous shale section will be the same for a given effective overburden pressure irrespective of its depth. This will be true for any area of uniform heat flow and will be the same whether the shale is overpressured or not.

Heat and time have been related to coalification and increase in vitrinite reflectance. In Fig. 1a and b the values of vitrinite reflectance are for the same samples, so the time-factor does not have to be considered in this comparison. Nevertheless, the comparison has important implications for the significance of time in coalification processes. The amount of time available for heating may influence the final state of maturation of vitrinite, coal or other hydrocarbons. From the excellent correlation of Fig. 1b it can be inferred that the time-factor in relation to precision of vitrinite reflectance estimates for given temperatures and pressures, is of limited significance on a geological scale and is likely to be critical only for a short period.

Further investigation of the combined effect of heat, pressure, thermal conductivity of sediment, and time in natural, geological conditions will improve understanding of the increase in reflectance of vitrinite. The resulting data should also provide a more sound basis for interpretation of the role of natural physical processes in the maturation of all types of organic matter in terms of physical chemistry.

Rejecting evidence of Gothenberg geomagnetic reversal in New Zealand

MORNER and Lanser¹, in 1974, gave evidence that the Gothenberg Geomagnetic Event had been discovered in New Zealand. The report was made prematurely, being based on remarks by Topping² in an address at the INQUA Congress in Christchurch, New Zealand, 1973. Further investigations, detailed here, show that the presumed evidence for the Gothenberg reversal was unsound.

Topping's presumption was based on measurements of palaeomagnetic polarities in 16 andesite boulders taken from two adjacent localities in a lahar. The lahar is between 9,540- and 12,450-yr-old (ref. 2) and is located at Bruce Road on the northwestern side of Mount Ruapehu, National Park, New Zealand. Eleven of the boulders displayed

reversed polarities, and Topping concluded that this was sufficient to prove that the lahar was hot when it flowed, and the boulders had not cooled to below their Curie temperatures until after the lahar had come to rest. The independently determined age of the lahar, based primarily on ¹⁴C measurements³, indicated correlation of the implied reversed geomagnetic field with the Gothenberg Event. If correct, this would have been the first record of the Gothenberg Event in the Southern Hemisphere, and in view of its importance more thorough investigation was obviously needed.

Therefore an additional 16 oriented boulders of andesite were taken from one of Topping's localities. Two, three or four samples, at different distances between the outer surface and centre, were taken from each boulder, and polarities were measured with a spinner magnetometer.

Only a few samples had been magnetically cleaned by Topping. They showed no sign of instability after thermal demagnetisation at 150 °C, and Topping assumed that the magnetisations of all his sample boulders were stable. The following more rigorous cleaning tests confirm that Topping's assumption was correct.

Samples from three of the newly collected boulders were thermally demagnetised step by step at 50° intervals between 100 °C and 600 °C, and samples from two others were a.c. demagnetised at peak field intervals of 10 mT up to 50 mT. Directional changes were negligible up to 500 °C for thermal demagnetisation and up to 50 mT for a.c. demagnetisation. The palaeomagnetic stability index of Briden³ was applied and confirmed these observations. From these stability indices a peak field of 10 mT was chosen as best for a.c. cleaning and a maximum temperature of 300 °C for thermal cleaning. The remaining samples were cleaned at either of the above values, approximately half by each method.

The magnetisation directions of samples from each individual boulder are in good agreement with one another. This shows that the material in each boulder was at rest while cooling from the Curie temperature.

The magnetisation directions of individual boulders seem to be random, showing that their natural remanent magnetisation (NRM) could not have been acquired by cooling after coming to rest in the lahar mound.

After cleaning, the mean inclination for all the boulders was –10° with a standard deviation of 35°, and the mean declination was 132° with a standard deviation of 72°. A *t*-test shows that the inclinations and declinations are randomly distributed at the 95% confidence level.

It is thus concluded that the volcanic material composing the boulders acquired its thermoremanent magnetisation (TRM) by cooling in a stable magnetic field before the boulders were involved in the lahar flow. During the lahar flow the rocks were below their Curie temperature, and when they came to rest were magnetically oriented in random directions. They therefore do not record a geomagnetic field direction and are not suitable for testing the existence in the Southern Hemisphere of the Gothenberg Reversed Event.

Non-biogenic fixed nitrogen in Antarctica and some ecological implications

TOTAL fluxes of nutrients in ecosystems and the biosphere have been estimated¹⁻³, especially for tropical and midlatitude regions, but no study has attempted to estimate the contribution of fixed nitrogen from the Antarctic ice sheet. Using data from analyses of South Pole ice, we estimate here that the mean annual accumulation of fixed nitrogen in the Antarctic ice sheet is 2.73×10^4 tonnes of nitrate (as N) and 1.88×10^4 tonnes of ammonium (as N). If annual snow accumulation approximates annual losses through calving of icebergs, blowing snow and melting of the bottom of ice shelves, then Antarctic Ocean surface waters will be enriched by 4.61×10^4 tonnes of $\text{NO}_3^- + \text{NH}_4^+$ during the austral summer. This contribution of fixed N to circumpolar surface waters may significantly influence productivity.

A total of 364 South Pole ice core samples from various depths were analysed for ammonium ion (phenol-hypochlorite method⁴), nitrate ion (diazotisation method⁵), and nitrate ion (cadmium reduction method⁵). These methods do not detect other reduced NH_x species which might be present in trace amounts. Details of corehandling and analytical methods are reported in Parker *et al.*⁶

Table 1 summarises our results. Almost no NO_3^- was found except in the upper few metres of snow contaminated by fuel combustion products⁶. Average annual accumulation rate estimates at the South Pole range over 6–10 cm of water⁷⁻¹⁰. Based on estimates of annual accumulation rates at various points, an average value of 10 cm of water per year for the entire ice sheet seems reasonable¹⁰. The continent measures $14\text{--}15 \times 10^6$ km² and is > 95% ice-covered with an estimated mean ice thickness of 2.0 km. Using 14×10^6 km² as the ice sheet area, total glacial ice volume is about 28×10^6 km³ with a mean density of nearly 1.0. The assumption that our measured nitrogen values are representative of the entire mass of ice is probably conservative, because coastal Antarctica receives additional nitrogen input from sources such as birds and coastal nitrogen-fixing biota. We calculate the following, assuming a mean density of 1.0 for glacial ice:

- (1) Mean annual NO_3^- input to the continent,
 $(14 \times 10^6 \text{ km}^2) \times (10^6 \text{ m}^2 \text{ km}^{-2}) \times (19.5 \mu\text{g NO}_3^- \text{ l}^{-1}) =$
 $2.73 \times 10^{10} \text{ g} = 27,300 \text{ tonnes} (= 121,000 \text{ tonnes of NO}_3^-).$
- (2) Mean annual NH_4^+ input to the continent,
 $(14 \times 10^6 \text{ km}^2) \times (10^6 \text{ m}^2 \text{ km}^{-2}) \times (13.4 \mu\text{g NH}_4^+ \text{ l}^{-1}) =$
 $18,800 \text{ tonnes} (= 24,100 \text{ tonnes of NH}_4^+).$
- (3) Mean annual $\text{NO}_3^- + \text{NH}_4^+$ input to the continent,
 $(1) + (2) = 46,100 \text{ tonnes} (= 145,100 \text{ tonnes of NO}_3^- + \text{NH}_4^+).$
- (4) Total $\text{NO}_3^- + \text{NH}_4^+$ contained in the Antarctic ice sheet,
 $922 \times 10^6 \text{ tonnes} (= 2.902 \times 10^9 \text{ tonnes of NO}_3^- + \text{NH}_4^+).$

This total fixed nitrogen in the Antarctic ice sheet is nearly five times Delwiche's³ estimate of annual world production from all sources.

Wilson and House¹¹, based on pooled samples of South Pole snow, calculated an annual infall of N (as NO_3^- plus NO_2^-) of 0.0045 lb per acre ($= 7.06 \times 10^6$ kg per year over the continent). Our calculations, which include NH_4^+ , indicate an average of 27.3×10^6 kg or nearly four times their estimate. Wilson and House¹¹ found no NH_4^+ , but they used the direct

Nezzlerisation method, which does not detect NH_4^+ below about $15 \mu\text{g N l}^{-1}$. We agree with Wilson and House that one probable mechanism for nitrogen fixation at the South Pole involves auroral activity, but we further propose that other stratospheric ionisation processes may add to the total fixed nitrogen in polar regions.

Our calculated NO_3^- and NH_4^+ annual input of 46,100 tonnes to the Antarctic ice sheet is only about 0.37% of Delwiche's³ estimate of 7.4 M tonnes per year for the world's atmospheric N fixation. The nitrate- and ammonia-N in Antarctic ice is probably from natural atmospheric sources, a view strengthened by the fact that our analytical data include > 50 m of the South Pole firn core covering over 400 yr (Parker, unpublished). If the primary mechanism of nitrogen fixation is related to stratospheric ionisation over Antarctica, one must expect that a similar condition prevails in the Arctic, although tropospheric mixing patterns will differ in the two regions. Assuming atmospheric N fixation in both polar regions to be approximately equal, then about 0.74% of Delwiche's³ total is produced in polar regions between lat 70° and 90° and > 99% is produced between lat 70°N and 70°S ; this latter zone includes about 80% of the earth's surface and has appreciably less auroral activity. Also, atmospheric nitrogen fixation by lightning^{12,13} and by photochemical oxidation¹³ is considered to be extremely small. Consequently Delwiche's estimate of 7.4 M tonnes per year for world atmospheric NO_3^- production may be excessive. Delwiche³ has emphasised that appreciable uncertainty may result because of difficulties in correctly estimating the proportions, in rainfall, of fixed nitrogen derived from atmospheric ionisation and from land or sea. Our data largely reflect inputs from purely atmospheric processes, because the South Pole is remote from land, sea, and global human activities, also because much of the ice core examined predates the advent of massive industrialisation, and biota such as nitrogen-fixing organisms are absent at the South Pole.

The contribution by the Antarctic ice sheet to the nitrogen balance of the Southern Ocean seems to be significant. The ice sheet is apparently in volumetric equilibrium. Approximately 1.4×10^6 M tonnes per year of N-laden Antarctic ice, therefore, enters Antarctic circumpolar waters either as icebergs or from blowing snow and melting of the bottom of ice shelves. The icebergs contain $19.5 \mu\text{g NO}_3^-$ and $13.4 \mu\text{g NH}_4^+$ l. Using the sum of these mean values, the annual contribution of inorganic nitrogen to the Southern Ocean is 4.61×10^4 tonnes.

Nitrate $-$ N values for Antarctic circumpolar surface waters vary from 0.02 to $21.4 \mu\text{g l}^{-1}$, with a mean value of 2.7 (refs 14, 15). Icebergs should contain about 7.2 times this concentration of nitrate. Little data on NH_4^+ for the Southern Ocean is available. Icebergs are not randomly distributed in Antarctic circumpolar waters, but follow relatively discrete routes dictated by surface currents¹⁶. As icebergs melt, the fresh, low-density water, enriched in nitrogen, will tend to rise and remain at the surface and within the euphotic zone. Nitrogen is recognised to be a nutrient limiting to productivity in some oceanic regions, but is not generally so in Antarctica where higher inorganic nitrogen concentrations occur relative to other seas^{14,15}. We suggest that N-laden ice originating on the Antarctic continent provides a major contribution to the nitrogen budget of the epipelagic zone of the Southern Ocean.

The area of the Antarctic Circumpolar Ocean, between the continental margin and the Subarctic Convergence, is about 14×10^6 km² (ref. 17). The depth of the mixed layer approximates 50 m, so the volume of the Southern Ocean into which the Antarctic nitrogen is injected is about $50 \text{ m} \times 14 \times 10^6 \text{ km}^2 = 7 \times 10^{14} \text{ m}^3 = 7 \times 10^{17} \text{ l}$. Using the estimate of mean NO_3^- concentration ($2.7 \mu\text{g l}^{-1}$) of Balech *et al.*¹⁴, the mixed layer reservoir of NO_3^- amounts to $(2.7 \mu\text{g l}^{-1}) \times (7 \times 10^{17} \text{ l}) = 19 \times 10^{11} \text{ g}$ or 19×10^6 tonnes of inorganic N (neglecting NO_2^- and NH_4^+). We have calculated above that the average annual input of NO_3^- from Antarctica is 2.73×10^4 tonnes, which is 7% of the total in the reservoir.

In spite of the general agreement that phytoplankton pro-

Table 1 Means, standard errors of the mean, and range of values for the two species of fixed nitrogen

Species	\bar{x}	s.e. \bar{x}	Range
NO_3^- -N	19.57	14.34	0-69
NH_4^+ -N	13.34	22.46	0-260

All values are in $\mu\text{g l}^{-1}$

ductivity is light (not nutrient) limited in the Antarctic, this input may have an effect completely out of proportion to its relative size because it is released into the euphotic zone at the time and place most beneficial to phytoplankton (that is, at the surface, as light begins to increase, both promoting photosynthesis and causing the icebergs to melt more quickly).

We thank the USNSF Division of Polar Programs, the core facility at the State University of New York, Buffalo, for the South Pole ice core, Drs R. Cameron, M. A. McWhinnie, and E. Shulenberger for helpful suggestions, and the Office of Naval Research for partial support of this research through grant no. N00014-77-C-0705.

Note added in proof: We have just confirmed that icebergs have concentrations near our estimates and that a concentration gradient occurs, descending with increasing distance from an iceberg.

Abscisic acid and guard cells of *Commelina communis* L.

THE plant hormone abscisic acid (ABA) is thought to be involved in the regulation of transpiration through its effects on stomatal aperture¹. Application of synthetic ABA causes stomatal closure in whole plants², shoots³ and leaf epidermal strips⁴. During water stress, levels of the hormone increase in plant tissues⁵, including the leaf epidermis⁶, and this is usually associated with stomatal closure⁷. There is evidence that ABA affects the ionic^{8,9} and metabolic⁹ status of the stomatal complex and it has been concluded that ABA acts directly on guard cells in effecting stomatal closure^{8,10,11}. There is, however, little information about the distribution of ABA in specific cells of the epidermis or about the sensitivity of the stomatal complex to ABA. We present here evidence that ABA can accumulate in the stomatal complex of *Commelina communis* L., a species used extensively in studies of stomatal physiology¹². The leaves of this plant yield relatively uncontaminated epidermal strips¹³ and this property has made it possible to calculate the apparent sensitivity of the stomatal complex to ABA. The evidence is based on experiments involving the uptake, distribution and metabolism of exogenous 2-¹⁴C-ABA.

Figure 1 shows that during 1 h when 2-¹⁴C-ABA was supplied through the transpiration stream there was a substantial increase in the radioactivity present in the lower epidermis. Stomatal closure was complete 9 min after application of ABA. These data enable us to calculate an upper limit

Fig. 1 Uptake of radioactivity by the lower epidermis of *Commelina* leaves fed 2-¹⁴C-ABA through the transpiration stream. Plants of *C. communis* were grown from seed and used when about 7 weeks old. Two-leaved shoots from non-flowering plants were pretreated to obtain open stomata by floating on water through which CO₂-reduced air was bubbled. After drying, they were stood in vials containing 2-¹⁴C-ABA solution (3 μ Ci ml⁻¹, 11.7 Ci mol⁻¹) 250 mm from two 60-W incandescent bulbs at ambient temperatures. Shoots were collected at various times and 50-mm² square abaxial epidermis samples were taken for radioassay (●) and autoradiography. The radioactivity present in the corresponding mesophyll plus adaxial epidermis square was also estimated and used to calculate the percentage of whole leaf radioactivity present in the lower epidermis (○). Radioassay was by liquid scintillation spectrometry after extraction for 3 h in 1 ml methanol:ether (1:1, v:v) mixture. Allowance was made for the quenching caused by the leaf material. Each point on the graph is the mean of three samples from one leaf. Estimates from 20 measurements of stomatal aperture from freeze-dried material indicated that closure was complete after 9 min of 2-¹⁴C-ABA uptake.

for the amount of ABA required to cause stomatal closure. Using an estimate of 50 stomata per mm², we calculate that the stomata had closed after receiving no more than 300 amol of ABA per stomatal complex. Because at the time of closure 5% of the total radioactivity was present in the lower epidermis, this represents 300 fmol per mm² leaf area. This figure confirms the data of Raschke¹¹ who calculated that 90–180 fmol of ABA per mm² leaf area was required to give 5% stomatal closure in *Commelina*. Kriedemann *et al.*¹⁴ estimated that 89–349 fmol of ABA per mm² leaf area was required to initiate closure in French bean, rose and *Zea* leaves.

Microautoradiography (Fig. 2a, b) reveals a distinct correlation between the aggregation of silver grains in the film emulsion and the distribution of stomatal complexes in the tissue. This is not restricted to the pattern of 2-¹⁴C-ABA uptake in isolated epidermes, because similar distributions of silver grains were obtained in autoradiograms from epidermes in which the label was applied through the transpiration stream for 1 h. Evidence from thin-layer chromatography suggests that more than 90% of the radioactivity present in methanol: ether extracts of epidermal tissue incubated in 2-¹⁴C-ABA for 1 h was chromatographically identical to ABA. The mobility of the labelled molecules was manifest in the fact that more than 80% of the radioactivity initially present in such tissue had been lost to the efflux medium after 90 min of incubation in 1 mM CaCl₂ solution. This indicated that distribution studies using ABA should be restricted to the techniques of soluble-compound autoradiography. Neither the net uptake nor the distribution pattern of radioactivity in isolated strips incubated for 1 h was significantly affected by pretreatments causing opening or closing of the stomata.

We have shown that radioactivity from labelled ABA becomes localised in the region of the guard cells of *Commelina communis* after two different treatments. It may be argued that the distribution found is commensurate with that expected of a hormone reaching its target cells. Nevertheless, several points need further clarification, particularly the following. (1) The time courses used for the autoradiography were longer than those required to cause stomatal closure; shorter presentation

times necessitating the use of extremely high specific activity labelled ABA are required. (2) The guard cells seem to be metabolically the most active cells in the epidermis¹⁵ and could be acting as metabolic sinks, although this does not necessarily deny a role for ABA in closure. ABA accumulation in guard cells may represent a form of compartmentalisation or sequestration away from active sites¹⁷. (3) There is evidence that ABA

affects solute distribution between epidermal cells and guard cells¹⁸, but the precise intracellular sites of ABA action remain to be elucidated.

Fig. 2 Distribution of radioactivity in lower epidermis tissue of *C. communis* leaves after floating on $2\text{-}^{14}\text{C}$ -ABA solution for 1 h. **a**, Aggregation of silver grains in the photographic emulsion. **b**, Position of guard cells in the associated freeze-dried *Commelina* epidermis (neutral red stained). $50\text{-}\mu\text{m}^2$ squares of abaxial epidermal tissue were taken from mature leaves of non-flowering shoots. These were floated for 1 h, cuticle uppermost, on 1 mM CaCl_2 solution containing $2\text{-}^{14}\text{C}$ -ABA ($4\text{ }\mu\text{Ci ml}^{-1}$, 11.1 Ci mol^{-1}) maintained at 27°C in a water bath. This solution was gently shaken. After incubation the tissue was rinsed five times for 20 s, with agitation, in 1 ml 1 mM CaCl_2 . Optional prestaining in an aqueous neutral red solution was carried out for 1 min before this. Open stomata were obtained as previously described and closed stomata by floating leaves on water in the dark. Thin-layer chromatography in four solvent systems (benzene:acetone:acetic acid, 70:30:1; ethyl acetate:toluene:acetic acid, 1:10:2; chloroform:methanol, 1:1; *n*-hexane:ethyl acetate, 1:1) was used to estimate radiochemical purity of methanol:ether extracts of epidermal tissue incubated in $2\text{-}^{14}\text{C}$ -ABA solution for 1 h. Efflux of radioactivity was estimated by floating such tissue, cuticle uppermost, on 1 ml of 1 mM CaCl_2 solution for 90 min and estimating the radioactivity present in the epidermis and efflux medium. The autoradiographic procedure was a modification of that used by Willmer *et al.*¹³. Epidermal tissue was applied, cuticle uppermost, to a subbed slide and immersed in liquid nitrogen before freeze-drying for approximately 12 h. The emulsion side of Kodak Pan-F film was applied directly to the tissue and held in place with another slide which was then taped to the first. The film was exposed for 3 weeks in a desiccator at -15°C before development. Controls for pressure artefacts and chemography¹⁶ proved negative scale bar, $100\mu\text{m}$.

Effect of abscisic acid on solute transport in epidermal tissue

AN important aspect of the stomatal mechanism in green plants is the transport of solutes into and out of guard cells in response to stimuli such as illumination¹. The effect of abscisic acid (ABA) in causing stomata to close has been ascribed to ABA-promoted solute leakage from guard cells². The experiments reported here show that leakage alone is insufficient to explain stomatal closure caused by ABA. The involvement of live epidermal cells, acting as recipients of solutes from guard cells, is necessary, as Penny and Bowling have suggested, especially when considering intact leaves³.

To test the requirement for live epidermal cells in ABA-mediated stomatal closure, epidermal strips of *Commelina communis* without living epidermal cells were floated on radioactive ABA in solution. The stomata remained open, but autoradiographs of the strips clearly showed that ABA had accumulated in the stomatal complexes as in untreated strips⁴ (Fig. 1).

We used two approaches to examine the effects of ABA on solute distribution between epidermal and guard cells. Neutral red staining of epidermal strips showed that treatment with ABA resulted in a diminished accumulation of stain in guard cells, and increases in both the rate of accumulation and the final concentration in live epidermal cells. Staining showed that where stomata were adjacent to ruptured epidermal cells the guard cells remained open after application of ABA (Fig. 2). If the transport of neutral red can be taken as an indication of solute transport, one can conclude that in ABA-treated tissue epidermal cells function as active(?) sinks for solutes from guard cells.

For a direct assessment of solute concentrations in epidermal cells, epidermal strips were treated or not treated with ABA while turgor was kept at the optimum epidermal water deficit^{5,6} by floating the tissue on mannitol solution.

Fig. 1 *a*, Photomicrograph of an epidermal strip of *Commelina communis* with stomata open. The strip had been illuminated while floating on a buffer solution at pH 4.5 to kill the epidermal cells². When stomata had remained open at a steady state aperture for 20 min the strip was transferred for 60 min to a solution of $1 \mu\text{Ci}$ DL-*cis-trans*-2-¹⁴C-ABA (11.7 Ci mol^{-1}). Stomata remained open although ABA had accumulated in stomatal cells as in (*b*). *b*, Autoradiograph of the strips shown in (*a*). Accumulation of ABA in the stomatal cells did not cause stomatal closure.

Under the influence of ABA there was an increase in the concentration of solutes in the epidermal cells probably functioning as recipients of solutes from guard cells. This resulted in a striking difference in the incidence of plasmolysis. In tissue floating on 0.2 M mannitol without ABA almost all epidermal cells were plasmolysed and stomata opened to the maximum extent. In tissue treated with ABA very few epidermal cells were plasmolysed and stomata were closed. This confirmed the indication, gained from neutral red staining, that solutes from guard cells accumulated in adjacent epidermal cells, and of necessity raised their turgor pressure. It could be concluded, however, that the latter played only a secondary role in ABA-mediated stomatal closure because stomata adjacent to slightly plasmolysed epidermal cells nevertheless closed in the tissue treated with ABA.

Although these experiments have clarified part of the mechanism of ABA action on the stomatal complex as far

Fig. 2 Photomicrograph of a microscope field of view ($\times 250$) of an epidermal strip of *Commelina communis*. Stomata had been opened in illuminated leaves kept in CO_2 -free air. ABA was supplied in the transpiration stream for 10 min. Epidermal strips were then taken and stained for 1 min by floating on neutral red (1:20,000), after which they were mounted in liquid paraffin. From the staining it was clear which epidermal cells had been ruptured and which had remained intact. Measurements were made of the effect of ABA on stomatal aperture, the rate of accumulation of dye in the different cells and the final intensity of stain in epidermal and guard cells. Rate of accumulation was measured by photographic recording on colour film. Intensity of stain was measured by transmittance at 600 nm in a Reichert Zetopan using the colour films obtained. Only those stomata which were adjacent to live (stained) epidermal cells had closed.

as solute distribution is concerned, the precise site of that action remains to be demonstrated. The effect could be restricted to the guard cells or may extend to other epidermal cells, especially the subsidiary cells whose exact role in *Commelina communis* is not fully known.

Characterisation of the surface coat of *Trypanosoma congolense*

THE protozoan parasites *Trypanosoma congolense*, *T. brucei* and *T. vivax* cause extensive disease problems to livestock in Africa¹. In many cases trypanosomiasis results from mixed infections due to all three species². Immunisation has not been successful because of the ability of the parasites to evade the host immune response by changing the antigenic structure of the surface coat³. Chemical and immunochemical characterisation of the surface coat of all three species should give insight into the mechanism of antigenic variation. Recent work on the surface coat of *T. brucei* demonstrates that antigenic variation is the result of a change in structure of a single, variant-specific, surface glycoprotein^{4,5}. No comparable information is available on the structure of the surface coat of *T. congolense* and *T. vivax*. We report here some properties of the surface coat of *T. congolense*.

An isolate⁶ of *T. congolense* (Transmara strain) was supplied by the Kenya Veterinary Laboratories. Clone X4 was derived from the Transmara strain by injecting a single trypanosome into lethally irradiated (900 R) mice. Trypanosomes of this clone were normally grown in irradiated mice and separated from infected blood⁷. Occasionally organisms were collected from normal rats after an additional 3 d passage with no change in surface antigen observable by analytical isoelectrofocusing (IEF), or immunofluorescence using a variant-specific antiserum.

Uncultured or cloned parasites were labelled by lactoperoxidase-catalysed ¹²⁵I iodination or by galactose oxidase oxidation followed by NaBH₄ (³H) reduction. Both enzymes are known to be unable to penetrate the lipid bilayer, and therefore the two methods are commonly used to detect exposed glycoproteins⁸. The adaptation of these labelling procedures to trypanosomes (see legends to Figs 1 and 2) allowed the analyses of surface coat presented here and provided markers for purification of surface material. The labelled coat was extracted by repeated freezing and thawing followed by centrifugation at 230,000g (60 min.). The presence of 1 mM *N*-tosyl-L-lysyl-chloromethane (TLCK) prevented proteolytic breakdown of the labelled material at least during separation into supernatant and pellet fractions at 4°C.

Between 60 and 80% of total radioactivity was present in the soluble supernatant fluid. Most of the remaining radioactivity was solubilised by treating the 230,000g pellet with nonionic detergent NP-40 (Shell) at 0.5% v/v for 30 min at

0 °C and centrifuging at 230,000g (60 min). Total labelled parasites and both aqueous- and detergent-solubilised supernatant fluids were analysed by 7.5–15% gradient polyacrylamide-sodium dodecyl sulphate gel electrophoresis (SDS-PAGE) in reducing and non-reducing conditions¹¹.

Gels were stained with Coomassie blue and destained before detection of radioactive components either by counting 2-mm gel slices or by autoradiography¹². Although a large number of proteins were stained by Coomassie blue throughout the gel length only one major peak containing both ¹²⁵I and ³H was consistently detected by SDS-PAGE of total parasites and soluble or insoluble extracts. The appearance of this peak was unchanged whether the preparations were derived from cloned or uncloned trypanosomes (Figs 1 and 2). The apparent molecular weight of the glycoprotein is 56,000. Gels run in non-reducing conditions gave similar results, and no dimers or oligomers were detectable. A few minor labelled peaks accounting for 1 to 5% of the total radioactivity were also detected by SDS-PAGE and are being analysed. The galactose oxidase catalysed labelling

Fig. 1 Autoradiograph patterns of ¹²⁵I *T. congolense* clone X4 surface proteins. *a*, 10⁷ Parasites solubilised with 2% SDS; *b*, water soluble 230,000g supernatant fluid and *c*, NP-40 soluble 230,000g supernatant fluid from the same number of parasites. The autoradiography shows that the sum of radioactivity in *b* and *c*, does not equal *a*, probably because of loss of material which occurs in separating the major labelled glycoprotein into water soluble and detergent soluble supernatant fluids; in addition a small portion of the radioactivity remains with the detergent insoluble pellet (not shown). The SDS-PAGE slab is 7.5%–15% acrylamide, stabilised with 10% glycerol in the 15% solution. Apparent molecular weights were determined using calibration curves obtained from protein standards subjected to electrophoresis on the same slab gel (see legend to Fig. 2). The method of Marchalonis *et al.*⁸ for enzymatic radioiodination of leukocytes was modified as follows: 2 × 10⁸ washed trypanosomes were resuspended in 50 µl 0.01M phosphate saline buffer, 1% glucose, pH 7.4 (PGS pH 7.4) containing 20 µg of lactoperoxidase (Sigma) and 250 to 500 µCi of Na¹²⁵I (Amersham). The reaction was initiated by the addition of 20 µl of 0.03% H₂O₂ and terminated after 5 min by adding a 100 times excess of PGS pH 8.0 (ref. 7). Two subsequent washes were carried out with the same buffer containing 1% foetal calf serum. Parasite motility was unimpaired at the end of the procedure.

Fig. 2 SDS-PAGE in reducing conditions of 230,000g supernatant fluid from uncloned *T. congolense*. Organisms were labelled on galactose and galactosamine(s) by galactose oxidase oxidation and NaBH₄ (³H) reduction. Molecular weight markers were: albumin (67,000), human IgG heavy chains (57,000), ovalbumin (45,000), human IgG light chains (25,000), bromophenol blue (BPB). ³H labelling of carbohydrates was achieved by modifying the method of Gahmberg⁹. Trypanosomes (2 × 10⁸) in 1 ml PGS pH 7.4 (buffer reference in legend to Fig. 1) were incubated with 1 unit galactose oxidase (Worthington) and 500 units catalase (Worthington) for 30 min. The parasites were then washed with PGS pH 8, resuspended in 1 ml of PGS pH 7.4 and NaBH₄ (³H) 6 Ci mmol⁻¹ (Amersham) was added to give a final concentration of 1 mM and a specific activity of 5mCi per 2 × 10⁸ trypanosomes. The reduction was carried out at room temperature for 15 min with occasional shaking. Termination of the reaction and washes of parasites were as for the iodination method (legend to Fig. 1). Parasites retained normal motility.

technique was used mainly to show the presence of carbohydrate moieties on the surface coat of *T. congolense*. We now routinely use only surface iodination for tracing the parasite coat.

Parallel studies carried out with *T. brucei* (LUMP 227) confirmed previous work showing that the surface coat consists of one major glycoprotein⁴. The apparent molecular weight of the *T. brucei* variant antigen is 62,000. A sample of purified variant antigen from *T. brucei* clone 052 (ref. 4) donated by G. A. M. Cross showed the same molecular weight when measured by the gradient SDS-PAGE technique. In *T. brucei* we also observed the same amount of insoluble glycoprotein as in *T. congolense*. The small difference in apparent molecular weight between the major surface glycoprotein of *T. congolense* and *T. brucei* could have one of several explanations, for example, a peptide bond of the *T. congolense* antigen might be subject to specific proteolytic degradation, or the extent of glycosylation might be very different in the two species.

Supernatant fractions of iodinated cloned and uncloned *T. congolense* were analysed by IEF in polyacrylamide gels. Uncloned material showed many peaks ranging in pI from 5 to 8. It is known that the surface coat glycoprotein of *T. brucei* is variant specific and in fact iodinated supernatant fluids from various *T. brucei* clones always showed one homogeneous peak with a specific isoelectric point (for example Fig. 3b). One might expect similar results for *T. congolense*; however, three peaks were resolved by IEF of a labelled supernatant fraction from clone X4 of *T. congolense* (Fig. 3a). Preparative purification of the surface glycoprotein from 2 × 10¹⁰ cloned parasites⁴ yielded about 1 mg of each of the three components (pI 6.2, 6.4 and 6.6).

An antiserum prepared in rabbit against the IEF peak of pI 6.6 stained > 99% of the parasites using immunofluorescence and showed a single precipitin line in immunodiffusion. Both aqueous- and detergent-soluble supernatant fluids were tested in immunoprecipitation as follows: supernatant fluids derived from 10⁶ parasites were incubated with

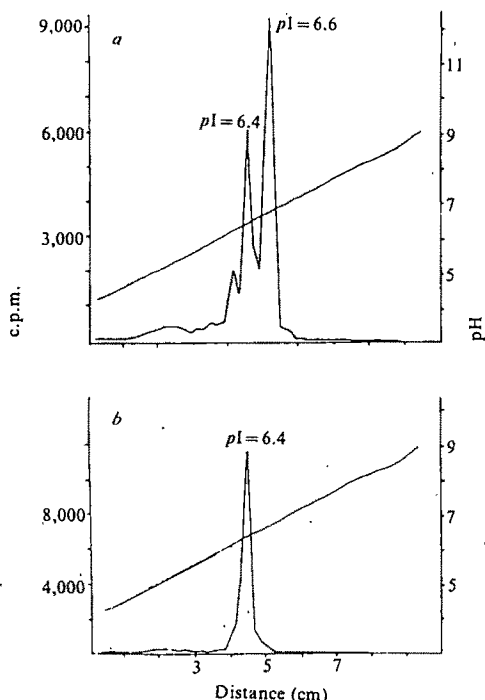

Fig. 3 *a*, A radioiodinated clone of *T. congolense* (X4) was freeze-thawed three times in water and separated into 230,000g (60 min) supernatant and pellet fractions. The supernatant fluid was dialysed against water at 4 °C then run across the width of a standard polyacrylamide gel isoelectrofocusing plate (pH 3.5–9.5) supplied by LKB. The gel was stained for protein with Coomassie blue and destained in ethanol–water–acetic acid (6:13:1). Radioactivity measurements were made on 2 mm fractions. (*b*), As (*a*) except that the radioiodinated trypanosomes were a clone of *T. brucei*.

rabbit anti-variant specific antiserum or normal rabbit serum as control for 30 min at room temperature. An optimal amount of sheep anti-rabbit immunoglobulin serum was added and the mixtures left at 4 °C overnight. Precipitates were washed three times with buffered saline, dissolved in 0.08 M Tris pH 6.8, 0.1 M dithiothreitol, 2% SDS and boiled for 5 min before electrophoresis. SDS-PAGE analysis of the specific precipitates showed the same 56,000 radioactive peak seen in Figs 1 and 2, as well as the protein with pI 6.4 which has a lower molecular weight (data not shown). No radioactive material was precipitated by normal rabbit serum.

These data suggest that an antigenically homogeneous clone of *T. congolense* yields a single specific glycoprotein as surface antigen and that the portion which is detergent-solubilised is immunologically indistinguishable from the soluble glycoprotein, although it possibly has a different attachment to the trypanosome plasma membrane. This might reflect a precursor-product relationship.

The heterogeneity of surface-labelled glycoprotein from cloned *T. congolense* observed from IEF is likely to be due to proteolytic degradation. Breakdown of the 56,000 molecular weight protein was observed even during separation of broken cells into supernatant and pellet fractions at 4 °C in the absence of TLCK. The extent of degradation was enhanced by any further purification procedures, and the final yield of purified variant antigen is far from satisfactory. Improvements of the solubilisation and purification procedures are in progress and will be published elsewhere.

There are several overall similarities between the surface coats of *T. congolense* and *T. brucei*. In both cases one glycoprotein is predominantly accessible to surface labelling; the distribution of surface glycoprotein between water soluble and insoluble fractions of broken cells is similar, as are the molecular weights. These results suggest the need

for comparable studies on *T. vivax* to provide a more unified understanding of basic surface coat structure in African trypanosomes.

We thank Ms J. Vernooij and Mr G. Mpimbaza for technical assistance.

Behavioural mutants of *Paramecium caudatum* with defective membrane electrogenesis

THE swimming behaviour of *Paramecium* is mostly dependent on the activity of its cilia¹, which are regulated by the intracellular cation concentration, which in turn is modified by Ca-dependent electrogenesis in the membrane^{2,3}. Behavioural abnormalities due to defective membrane electrogenesis have been found in mutants of *P. tetraurelia*^{4–7}. We have now found similar abnormalities among a group of behavioural mutants of *P. caudatum*. These show promise of an excellent source of genetic markers.

Unlike *P. tetraurelia*, *P. caudatum* does not exhibit natural autogamy⁸, and is therefore a less convenient source of homozygous clones. Strain Kyk201 (mating type VI of syngen 3), however, which we used, shows frequent selfing conjugation so that recessive mutant genes should be expressed. The progeny of selfing conjugations show a high rate of survival.

P. caudatum in the logarithmic phase in fresh lettuce medium with *Klebsiella aerogenes*⁹ were treated with the mutagen *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (10 µg ml⁻¹) for 40 min and then cloned. After the isolated cells had divided 12–15 times, clones were starved to induce selfing conjugation¹⁰. Those containing many conjugating pairs were fed again with bacterised medium to induce five to eight more cell divisions. Then the progeny were subjected to galvanotactic and geotactic¹¹ screening. Every cell which showed abnormal swimming behaviour in an electric field was pipetted into a separate dish to make an independent clone. The subsequent progeny were compared with the wild type with respect to swimming behaviour in response to various stimuli and with respect to electrophysiological characteristics.

The wild type makes an avoiding response due to a transient ciliary reversal when it encounters an obstacle. It may also do this spontaneously. It makes repetitive avoiding responses at fairly regular intervals in a mixture of Ba²⁺ and Ca²⁺ (ref. 12) ('barium dance', Fig. 1*a*), and undergoes longer term ciliary reversal (about 1 min) when K⁺ is above a certain concentration in the external medium¹³. Depolarisation of the membrane by an outward electric current causes ciliary reversal in the wild type¹⁴. This reversal is always associated with an inflow of Ca²⁺ through the membrane due to an increase in Ca permeability^{2,3}. Ca is a mediator for the coupling of membrane permeability with ciliary reversal¹⁵.

As summarised in Table 1, none of these behavioural responses due to ciliary reversal was seen in mutant 13B

Table 1 Swimming behaviour and ciliary responses to various stimuli in mutants of *P. caudatum*

Strain	Swimming velocity (µms ⁻¹)	Avoiding response	Escape response	Ciliary reversal by outward current	Ciliary augmentation by inward current	Ciliary reversal by K ⁺ (s)	Barium* dance
Wild type							
Kyk201	1384 ± 27	+	+	+	+	43.6 ± 4.8	+
Mutants							
13B (CNR)	1548 ± 27	—	+	—	+	0	—
13D (K ⁺ sensitive)	1108 ± 32	+	+	+	+	255.6 ± 31.0	—
11C (slow swimmer)	864 ± 16	+	+	+	+	26.3 ± 6.1	—

+ and —, Presence and absence of the response respectively. All measurements were made at room temperature (20°–25 °C). Swimming velocity was measured by Dryl's method¹² in a mixture of 4 mM K⁺, 1 mM Ca²⁺ and 1 mM Tris-HCl (pH 7.2). The duration of ciliary reversal was measured when the specimen was transferred from a mixture of 1 mM K⁺, 1 mM Ca²⁺ and 1 mM Tris-HCl (pH 7.2) to a mixture of 20 mM K⁺, 1 mM Ca²⁺ and 1 mM Tris-HCl (pH 7.2). The figures represent the average and standard error of 10–20 measurements in different specimens.

* Repetitive avoiding response in association with all-or-none type action potentials shown in a mixture of Ba²⁺ and Ca²⁺.

(Fig. 1*b*). It showed no ciliary reversal in response to various stimuli. Electrophysiological examination revealed that, in contrast to the wild type^{16,17}, it produced no regenerative Ca action potential in response to a depolarising current (Fig. 2*a* and *c*). Only a residual active Ca²⁺ response was detectable when the current was very strong and the potential response was displayed in a form of phase plane trajectory¹⁸ (Fig. 3*a*, *b*, *d* and *e*). However, ATP-reactivated cilia of Triton-extracted specimens of 13B (which have a disrupted cell membrane) were reversed in their beating orientation when the Ca²⁺ concentration in the reactivation medium was raised above 5 × 10⁻⁶M, as happens with similarly treated wild type specimens^{15,19}. Externally applied Ca has direct access into such cells and can influence the Ca²⁺-sensitive reversal mechanism of cilia without restriction by the membrane. Thus, the reversal mechanism of the cilia is functional in mutant 13B, and the behavioural deficiency is probably due to a defect in the depolarisation-sensitive Ca gating system in the membrane. We shall now refer to mutant 13B as CNR (caudatum non-reversal).

A transient increase in forward swimming speed due to increased beat frequency of the cilia in the normal direction (ciliary augmentation) was observed in CNR, as in the wild type, in association with a hyperpolarising mechanoreceptor potential after mechanical stimulation of the posterior membrane²⁰ (Table 1, Fig. 2*f* and *h*). An injection of inward current into a CNR cell always caused ciliary augmentation in

association with an increase in K⁺ permeability of the membrane, as in the wild type²¹ (Table 1, Fig. 2*b* and *d*, Fig. 2*c* and *f*). Thus both the mechanosensitive K gating system in the posterior membrane and the hyperpolarisation-sensitive K gating system in the general membrane remain intact in the CNR specimen.

Mechanical stimulation of the anterior membrane of a CNR cell induced a transient depolarising mechanoreceptor

Fig. 2 Responses of the membrane potential to constant current stimulation (*a–d*) and mechanical stimulation (*e–h*) in *P. caudatum*. *a*, *b*, *e* and *f*, Wild type specimen; *c*, *d*, *g* and *h*, CNR mutant. *E_m*, membrane potential: dashed lines show the resting level, and upward and downward deflections correspond to depolarisation and hyperpolarisation of the membrane, respectively. *S_i*, transmembrane current: dashed lines show zero current level, and upward deflection means outward current while downward deflection means inward current. *S_m*, deflection in the trace shows the duration and relative intensity of the electric pulse activating a piezoelectric crystal to drive a glass rod against the surface of the cell. The horizontal line in the centre of the figure corresponds to 20 ms in *a*, *b*, *c* and *d*, and to 40 ms in *e*, *f*, *g* and *h*. The vertical line corresponds to 20 mV for *E_m*, 4 nA for *S_i* and to 2 V s⁻¹ for *E_m*.

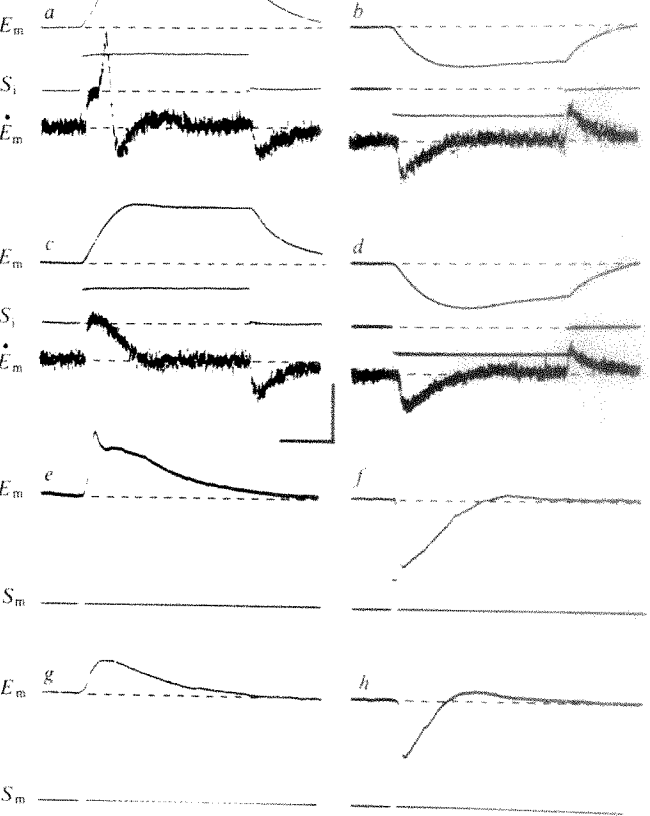

Fig. 1 Swimming behaviour of *P. caudatum* in a mixture of 1 mM BaCl₂ and 1 mM CaCl₂ (buffered to pH 7.2 by 1 mM Tris-HCl). The photographs were taken under dark-field illumination with an exposure time of 4 s (room temperature 25 °C). *a*, Wild type specimens (strain Kyk201) show repetitive avoiding response, which makes the specimen follow a zig-zag or star-shaped swimming path (barium dance). *b*, CNR mutants (strain 13B) do not dance, but continue to swim forward following a long-pitched, spiral path similar to that followed by the unstimulated wild type. The bar corresponds to 1 mm.

Table 2 Cross breeding analysis between wild type and beavioural mutants in *P. caudatum*

Cross	Generation	Phenotype		χ^2 and <i>P</i>	Survival (%)
		mutant	wild type		
13B × Kyky 1	F ₁	0	85	$\chi^2 = 0.01$ <i>P</i> = 0.9–0.95	60.7
	F ₂ Observed	4	15		22.6
	Expected	4.8	14.2		
11C × Kyky 1	F ₁	0	28	$\chi^2 = 0.10$ <i>P</i> = 0.7–0.8	20.0
	F ₂ Observed	10	25		27.6
	Expected	8.8	26.2		
13D × Kyk201	F ₁ Observed	11	17	$\chi^2 = 0.64$ <i>P</i> = 0.3–0.5	66.7
	Expected	14	14		

potential, which, as expected, was not followed by a regenerative Ca action potential of the general membrane (Fig. 2g). Weak reversal was observable only in the cilia on the mechanically stimulated anterior membrane. In wild type cells a regenerative Ca action potential was always accompanied by an anterior mechanoreceptor potential (Fig. 2e), caused by an increase in Ca²⁺ permeability on mechanical stimulation²². Thus the mechanosensitive Ca gating system in the anterior membrane is functional in CNR cells. Electrogenetic malfunction in the membrane of CNR is restricted to its voltage sensitive Ca gating system.

Mutant 13D showed remarkably long-lasting backward swimming, due to ciliary reversal, when transferred to K⁺-rich medium (about five times as long as for the wild type, Table 1). The resting membrane potential of 13D cells was much more depolarised than that of the wild type (about twice as much)

by an increase in the external K⁺ concentration, especially in the lower concentration range (0.5–4.0 mM). The resting membrane of 13D therefore has a higher K⁺ permeability than the wild type²³. We shall call 13D specimens 'K⁺-sensitive'. K⁺-sensitive showed a more marked increase in K⁺ permeability than wild type in response to an inward current. This was demonstrated in a phase plane trajectory as a shift in the membrane e.m.f. toward the K⁺ equilibrium potential (hyperpolarising direction) when the inward current stopped (compare Fig. 3h and c). Electrical responses of K⁺-sensitive to an outward current were essentially similar to those of the wild type (Fig. 3a and g).

Mutant 11C was distinctive for its slow swimming speed, being about half as rapid as the wild type (Table 1). Forward swimming of ATP-Mg²⁺-reactivated Triton-extracted cells of 11C was significantly slower than that of the wild type (171.2 ± 10.6 μm s⁻¹ in 11C, 234.5 ± 17.2 μm s⁻¹ in the wild type at 25 °C)^{24,25}. This, together with the fact that the electrophysiological characteristics of the specimen were essentially similar to those of the wild type, indicates that the slower swimming of 11C is due primarily to some malfunction in its ciliary motile system. We shall call 11C 'slow swimmer'.

We investigated gene differences between the mutants and the wild type by cross breeding. As Table 2 shows, when CNR or slow swimmer was crossed to a wild type (Kyky 1), all F₁ progeny had wild type behavioural characteristics. Phenotypic segregation occurred in F₂ clones with an expected ratio of 1:3. Therefore the abnormal behaviour of CNR and slow swimmer is under the control of a single recessive gene²⁶, designated *cnrA* and *sl* respectively. In the case of K⁺-sensitive, the F₁ segregated phenotypically into those with K⁺-sensitive characteristics and those with wild type characteristics in a ratio of 1:1. Therefore we consider that the high K⁺ sensitivity of K⁺-sensitive specimens is controlled by a dominant gene, K⁺S.

These mutants were isolated in R. Eckert's Laboratory at the University of California, Los Angeles, with the support by grants from the US PHS and NSF. The work was also supported by grants from Mitsubishi foundation and the Ministry of Education of Japan. We thank R. Eckert, S. Hagiwara, C. Kung and K. Hiwatashi for valuable discussions. We also thank M. Knutson for technical assistance and D. Fujii for help with the manuscript.

Scanning transmission electron microscopy of unstained biological sections

THE scanning transmission electron microscope (STEM) has made possible the direct visualisation of single heavy atoms¹ and, by exploitation of the high dark-field detection efficiency, has been used successfully for the imaging of stained and unstained biological specimens². We report here some preliminary results which indicate that STEM can also be utilised for the imaging of unstained biological sections.

The use of STEM for biological electron microscopy has several advantages over conventional transmission electron microscopy. The irradiation dose is easily controlled by shifting the scanning raster to an adjacent area for focusing and stigmation and by the use of image storage devices (scan converters) and beam blanking. Simultaneous use of several imaging modes (for example, bright- and dark-field) combined with analogue or digital image-processing techniques can be used to enhance 'on-line' the contrast of difficult biological specimens as described in this paper. Additionally, micro-analysis of easily identified specimen areas can be carried out *in situ* by energy-dispersive X-ray spectroscopy or electron energy-loss spectroscopy.

The material we have used for this work has been sectioned rigor flight muscle from *Lethocerus cordofanus*. This material was chosen because it has well defined structure, recognisable at both low magnification (the sarcomere repeat) and at higher magnification (the actin and myosin filaments and cross-bridges), and because an objective assessment of the image resolution can be made by the use of optical diffraction. The muscle was fixed with glutaraldehyde and embedded in araldite as described previously³, except that the osmium fixation and staining were omitted.

The microscopy was carried out on a V.G. Microscopes HB5 STEM operating at 100 kV with a cold field-emission source, an annular dark-field detector and a magnetic sector electron spectrometer as bright-field detector. Images were recorded directly from the photographic display screen on to 35 mm film which could be used without further processing for optical diffraction measurements. In order to minimise specimen dosage at high magnification, the microscope was used in a 'single shot' manner, that is, the image from a single scan at lower magnification was stored on a scan converter and redisplayed, with the electron beam blanked, in order to select a suitable area of specimen. The magnification was then increased and an area immediately adjacent to the selected region used for focusing. Finally, the scan raster position was shifted over to the appropriate position and the image recorded 'blindly' on film and simultaneously on the scan converter. The scan converter image was then redisplayed to assess various parameters, including the quality and correctness of focus of the recorded image. The total electron dose at the specimen was measured with a Faraday cage fitted directly above the specimen position.

To obtain sufficient contrast from a specimen where the contrast producing mechanism is the small difference in electron scattering between protein and the surrounding matrix of

Fig. 1 STEM micrograph of unstained insect flight muscle section, original magnification 50,000 \times . This is a mixed-signal bright-field image, so that electron dense material appears dark. The central vertical dark region is the M band, the less dense vertical region to the right, the Z band. Scale bar, 0.2 μ m.

embedding material, and to obtain an acceptable signal-to-noise ratio, it was necessary to use a mixed-signal mode of imaging. This had earlier been proposed for heavy atom imaging¹ and has been used for visualisation of unstained protein in ferritin particles⁴. The microscope was adjusted to give equal simultaneous signals in the dark-field and incoherent bright-field modes of operation. The two signals were then mixed in the algebraic mode $(BF - DF)/(BF + DF)$, and the mixed signal used to produce the final image. The resulting mixed signal has higher contrast for a given signal-to-noise ratio than either signal taken alone, and has the advantage that noise introduced by fluctuations in the electron beam is cancelled out by the division.

A typical image of unstained insect flight muscle is shown in Fig. 1. This was recorded with a 'single shot' after focusing on an adjacent area as described above, with a total electron dose, at an instrument magnification of 50,000 \times , of less than 25 electrons \AA^{-2} . The appearance of the thick and thin filaments is similar to that seen in stained sections and the cross-bridge structure can be seen weakly. The appearance of the M and Z bands is, however, different. The M band appears much darker than in stained sections, whereas the Z band, which stains very heavily, here appears to have a similar average density to that of the rest of the sarcomere. The appearance of the Z band was, in fact, somewhat variable, often being a little denser than the surrounding sarcomeres, but never appearing as dense as when seen in stained sections. It is not possible to say what these

Fig. 2 STEM micrograph, taken at magnification 100,000 \times . The dark region to the right is the M band. At this magnification, thick and thin filaments, and cross-bridges are visible. The narrow dark line to the left is the boundary of the previous scan. Loss of material has taken place to the left of this line, causing a distortion of the filament pattern.

Fig. 3 Optical diffraction pattern taken from the image of Fig. 2. (The pattern has been rotated through 90° relative to the image.) There are strong reflections along the 380 Å and 190 Å layer lines, the 540 Å layer line is also clearly visible, and the 140 Å meridional reflections are weakly present.

density differences mean in terms of material present, but an attempt is being made to quantify the image density-mass thickness relationship.

Figure 2 shows an image taken at $100,000\times$ magnification, again by focusing and adjusting instrumental astigmatism off the area to be imaged. One of the main difficulties in working with unstained material is the very rapid loss of material (etching) which takes place during each scan. At the boundary between the two scans, there is a marked distortion of the filament pattern and a lower density in the region to the left that has been exposed to two consecutive scans. Some variation in density can be seen along the thin filaments, and cross-bridges can be distinguished quite clearly. An optical diffraction pattern of this image is shown in Fig. 3. The resolution in the equatorial direction extends to about 65 Å and in the meridional direction to about 148 Å. The overall resolution is close to that obtained for stained sections, and weaker intermediate layer lines⁵ were visible. The images shown in Figs 1 and 2 were of sections in the thickness range 600–800 Å. Work in progress on other materials indicates that good contrast can also be obtained for thinner sections.

These results indicate that for unstained biological material, conventionally fixed and embedded, resolutions approaching those obtained for stained sections (that is, the limit imposed by the preparative technique itself) can be obtained by STEM mixed-signal imaging. It is hoped that resolutions may be extended by improved specimen preparation methods, including cryo-techniques⁶, or in the case of periodic structures, by using low-dose imaging⁷. A further important advantage of the ability to image unstained material is the combination of this form of imaging with the use of STEM for X-ray microanalysis. Preliminary results indicate that secondary X-ray detection with a sensitivity at least a factor of 10 higher than that obtainable by conventional X-ray dispersive systems, and probe sizes down to a few angstrom units in diameter, is possible. The two techniques used together will provide a powerful tool for the characterisation of elemental distribution in biological materials.

We thank Mrs B. M. Luke and B. Bullard, Department of Zoology, Oxford University, for providing the insect muscle sections.

Cellular glutathione is a key to the oxygen effect in radiation damage

OXYGEN is known to enhance biological changes induced by ionising radiation^{1,2}. The changes include chromosome breaks in *Tradescantia*³, mutation production in *Drosophila*, maize and bacteria^{3–6}, and rate of mitosis in grasshopper neuroblasts⁷. The biological and physical bases for the various enhancements remain obscure, and it has not yet been established that they are the result of a common mechanism. The quantitative aspects of the relationship between oxygen concentration and radiation response have been measured: for example, killing of *Escherichia coli* by X-ray radiation at a constant radiation dose⁸ and various interpretations of the quantitative aspects of the response base have been made^{9–12}. Ionising radiation has been proposed to interact with water to produce several products and these products interact with cellular material to produce the biological effects observed. In the reactions proposed, cellular sulphhydryl groups are supposed to be a primary cellular constituent which is reactive with the radiation products from water. We report here that one major cellular sulphhydryl constituent, glutathione (GSH), is apparently the major component in the interaction between radiation products and the cell, for cells unable to synthesise glutathione cannot be protected against killing by ionising radiation by reduction of the external oxygen concentration.

The response of GSH⁺ *E. coli* strain to irradiation in cellular suspension bubbled with air and argon (99.999% pure) is shown in Fig. 1. The isoefficiency dose ratio, that is, that dose ratio that gives equivalent survival in air and in the absence of oxygen⁹—now probably better known as oxygen enhancement ratio (OER), is about a factor of three. That is, in the presence of oxygen, ionising radiation is

Fig. 1 The oxygen effect with a GSH⁺ *E. coli* strain. ■, Survival in cell suspension bubbled in air; ○, survival of suspension bubbled for 10 min with argon. Cells grown in Penassay broth, washed, and irradiated in phosphate buffer, pH 6.9. Dose rate 2,230 rad min⁻¹ from a ⁶⁰Co source. Post-irradiation plating incubated at 30 °C.

Fig. 2 The lack of a protective effect of argon treatment (oxygen removal) on a GSH⁻ *E. coli* mutant¹³. ○, GSH⁺ strain bubbled with argon; ■, GSH⁻ strain bubbled with argon; △, GSH⁻ strain bubbled with air. In this experiment, a spectinomycin-resistant derivative (20 µg ml⁻¹ spectinomycin) was selected in the GSH⁻ strain, and cells from a culture of it mixed with its spectinomycin-sensitive parent in buffer and irradiated. Plating on media with and without spectinomycin permits discrimination. Incubation at 30 °C. Dose rate, 2,230 rad min⁻¹.

about three times more effective than in its absence, or near absence.

A glutathione deficient mutant (GSH⁻)¹³ does not show the increased survival of its parent in the absence of oxygen (Fig. 2) and it is presumed that the response is related to its inability to synthesise glutathione. It should be noted that in the experiment of Fig. 2, a spectinomycin-resistant derivative mutant of the GSH⁻ strain was used in mixed suspension with its wild-type GSH⁺ parent: the mixed suspension irradiated and plated on media (±spectinomycin) permits counting of both GSH⁺ and GSH⁻ strains irradiated in the same suspension and in identical irradiation conditions.

The spectinomycin resistance of the GSH⁻ strain is not responsible for the radiation response, for its spectinomycin sensitive parent is not made more resistant to radiation by reduction of external cellular oxygen (data not shown).

Five experiments on the GSH⁻ mutant all gave the same result and clearly show that the GSH⁻ *E. coli* cells cannot be protected against radiation by oxygen removal.

A reversion of the GSH⁻ strain was selected on the basis of faster growth rate in broth than its parent, and the glutathione content of it, the parent, and the wild type measured by a modification of the procedure of Fuchs and Warner^{13,15}. The glutathione contents were (nmol per mg protein): GSH⁺, 17.6; GSH⁻, 0.27; the GSH⁺ reversion, 10.1.

The GSH⁺ reversion was irradiated in the presence of air and in suspension bubbled with argon to remove oxygen. The results of this experiment are shown in Fig. 3. Clearly, the reversion shows a response qualitatively similar to the wild type, and quantitatively, based on its GSH content, to irradiation in reduced oxygen.

The mechanism by which cellular glutathione protects against ionising radiation damage in the presence of oxygen

is not known. A simple question can be dealt with, however. Can growth of the GSH⁻ deficient mutant in the presence of glutathione protect the cells against radiation damage under reduced oxygen tension? The results indicate that this is so; GSH⁻ mutant cells grown in glutathione, washed and resuspended in buffer are consistently more resistant to radiation under reduced oxygen tension: 3,100-fold; 44-fold; 41-fold; 100-fold; 10-fold; 8-fold in six separate experiments. Some variable phenotypic reversal can be achieved.

Indirect effects of ionising radiation have been reviewed^{16,17}, and recent summaries of substances that sensitise to radiation presented^{18,19}. Quantitative relationships between radiation response and oxygen tension have been considered linear¹², but this assumption is probably not correct¹¹. Despite these studies, the biochemical basis for the oxygen effect remains obscure.

It has been speculated that the oxygen effect is related to cellular sulphhydryl groups because of the reactive nature of these groups with oxidising radicals produced by irradiation of water. A horizontal study of a number of bacterial strains, attempting to relate radiation resistance to GSH content has been reported²¹. The results presented above limit this view to the oxygen effect. In addition, since total cellular GSH groups are not reduced in GSH⁻ mutants^{13,14}, it suggests specificity to GSH and not sulphhydryl groups *per se*.

The nature of this specificity remains to be determined, and it is not known in what manner GSH participates in cell protection, or at what stage in the radiation process it is needed. Growth in the presence of GSH seems to partially reverse the phenotype of the GSH⁻ mutant, and these experiments need to be expanded as well as a study of the effects of post-radiation addition of GSH.

Methyl glyoxal and diamide [diazene dicarboxylic acid, bis(*N,N*-dimethylamide)] have been shown to reverse the

Fig. 3 Survival of a spontaneous GSH⁺ reversion of the GSH⁻ strain. ■, Bubbled with air; ○, bubbled with argon. Cell growth, preparation and irradiation of cells as in Figs 1 and 2. Reversion to GSH⁺ has restored qualitatively the response to oxygen removal, and almost quantitatively the amount of resistance, since the reversion has only about 50% the GSH content of the wild type. Compare with Fig. 1.

protective effect of anoxia^{18,20}. Since these compounds are reagents reactive with sulphhydryl groups, perhaps specifically with GSH, the mechanism by which they act can now be understood. Presumably, destruction of cellular GSH by these reagents makes cells phenotypically identical to the GSH⁻ mutant.

This research was supported by USNSF grant BMS 7507343. We thank Drs Fuchs and Warner, and Apontoweil and Berends for supplying bacterial strains.

Note added in proof: Since the above experiments were conducted, we have received a γ -glutamyl cysteine synthetase mutant, and an independent glutathione synthetase mutant from Apontoweil and Berends¹⁴. Both of these strains cannot be protected against ionising radiation damage by oxygen removal.

Parallel induction of sister chromatid exchanges and infectious virus from SV40-transformed cells by alkylating agents

ALTHOUGH little is known about the biochemistry of the formation of sister chromatid exchanges (SCEs), it has been suggested^{1–3} that they reflect some aspect of cellular DNA repair. Because agents that promote SCE formation (for example, refs 2, 3 and 6–9) also induce infectious virus from certain SV40-transformed hamster cell lines^{10,11} and because evidence suggests that virus induction involves DNA repair^{12,13}, we have investigated a possible correlation between virus induction and SCE formation. We tested both events in the same cells in identical conditions. Parallel dose-response curves for both SCE formation and induction of infectious SV40 virus were observed with two alkylating agents, mitomycin C and ethyl methane sulphonate (EMS), which required effective concentrations differing by a factor of 10,000.

We used four clones of SV40-transformed hamster kidney cells, differing in their capacity to produce infectious virus¹¹. Clone A cells and to a lesser extent clone E cells release virus spontaneously. In both cell lines, as well as in clone B cells, which have not been found to produce virus spontaneously, virus induction can be stimulated as much as 10^3 – 10^4 -fold by exogenous agents such as mitomycin C¹¹. Clone G is a non-producing, non-inducible cell line while BHK-21 is an untransformed hamster kidney cell

Fig. 1 Detection of SCEs and their induction by mitomycin C in hamster metaphase chromosomes by BRdU-33258 Hoechst-Giemsa methodology²¹. SV40-transformed hamster kidney cells (clone G) were grown for 24 h in medium (Eagle's minimal essential medium (Gibco) with four times the usual concentration of vitamins and essential amino acids (MEM $\times 4$), 10% foetal calf serum (Gibco), 2 mM glutamine, penicillin (250 U ml⁻¹, and streptomycin sulphate (250 μ g ml⁻¹) containing 2.5×10^{-5} M BRdU. Cell collection and slide preparation using 33258 Hoechst dye and Giemsa stain were as before^{22,23}, except that: *a*, a high concentration of colcemid (Calbiochem; final concentration 8 μ g ml⁻¹) was added for the final 6 h as the control; *b*, mitomycin C (0.03 μ g ml⁻¹) was added 18 h before cell collection.

line which was used as a control. Duplicate samples of cell cultures were grown in the presence of BRdU, exposed to alkylating agents, and, at appropriate times, assayed either for SCE formation or production of infectious virus.

As previously described for other cell types, SCEs were detectable as reciprocal alterations in staining intensity along metaphase chromosomes of hamster cells which had incorporated BRdU for two divisions (Fig. 1*a*). An average of 11 SCEs was observed per metaphase in uninduced clone G cells. Treatment with mitomycin C (0.03 μ g ml⁻¹) increased the average frequency of SCEs in these cells to 88 per metaphase (Fig. 1*b*).

The average frequency of SCE formation, normalised per chromosome number of each cell line, increased in all lines in proportion to the dose of either inducing agent (Figs 2*a*, *b*). Mitomycin C was effective in inducing SCEs at much lower concentrations than was EMS. For example, a fourfold increase in SCEs over baseline frequency was caused by mitomycin C, in a concentration of less than 20 μ g ml⁻¹ but required EMS at approximately 300 μ g ml⁻¹. Similar frequencies of baseline and induced SCEs were observed for all cell lines. Chromosomal aberrations increased with increasing doses of inducing agent, averaging 3–4% of the number of SCEs. Aberrations were not always detected at the lowest concentrations of inducing agent, whereas SCEs were always measurable and are therefore more sensitive indices of response to the agents.

Virus yields paralleled SCE frequency in their response to increasing doses of mitomycin C or EMS (Figs 2*c*, *d*). Absolute levels of virus production were significantly different in clones A, E and B, although the relative responses of the cells to mitomycin C and EMS were similar. Cell survival, as measured by colony-forming ability, was approximately the same for each virus-producing cell line within the concentration ranges used of either agent.

Interclonal differences in absolute virus yields could depend on several factors, such as the nature or sites of viral genome integration, completeness of the integrated genome or mechanisms controlling viral genome excision, replication, transcription or post-transcriptional events. Whatever the explanation, all virus producers showed an induction response which paralleled the SCE increase.

All experiments were performed in the presence of

BRdU, which can induce SCEs^{2,6,8} and certain DNA and RNA viruses in normal and/or transformed cells¹⁴⁻¹⁷. In the hamster clones used in this study BRdU increased the absolute yield of SV40 two to fivefold but had little effect on the dose-dependent response to alkylating agents. The details of BRdU effects on DNA and RNA virus induction are under investigation.

The mechanisms of virus induction and SCE formation may involve DNA repair with some enzymatic features in common. DNA breakage seems to be associated with virus activation from transformed cells containing integrated viral genomes¹¹. Caffeine, which causes the accumulation of gaps in DNA damaged by ultraviolet light in rodent cells, by inhibiting post-replication repair, stimulates the induction of SV40¹³ and SCE¹⁸ by ultraviolet light. It might be the persistence of gaps which results in this enhancement. Pathways of DNA repair, perhaps related to recombinational events and analogous to SOS functions in prokaryotes¹⁹ and possibly in eukaryotes²⁰, may be involved in SCE formation. An association of SCE formation with an error-prone repair process could account for the observed correlation between SCEs, mutagens and carcinogens.

The exact relationship of SCE formation and virus induction remains to be determined, although the two

events show a striking correlation. Further examination of their temporal connection and biochemical characteristics in relation to cellular DNA repair processes may help to explain their biological significance. In any case virus induction is a highly sensitive biological marker for further studies on the mechanism(s) of DNA repair and SCE formation in mammalian cells.

Induction of autoreactive T lymphocytes and their suppressor cells by cyclophosphamide

THERE is increasing evidence of potentially autoreactive cells in normal animals^{1,2}. Expression of autoimmunity, however, may not arise as a primary effector cell abnormality but more possibly as the consequence of a defect in a thymus-dependent control mechanism³⁻⁵. Cyclophosphamide (CY) enhances the capacity of mice to give T cell-dependent responses, such as delayed type hypersensitivity (DTH) induced by sheep red blood cells⁶. It was suggested that B cells were the targets of CY action⁷ and that the enhanced DTH reaction was due to inhibition of antibody production and consequently to lack of the antigen-antibody complexes responsible for inhibition of DTH. Askenase *et al.*⁸ presented evidence for an alternative explanation for enhancement of DTH by CY. They demonstrated augmented DTH to sheep red blood cells with doses of CY which did not influence antibody responses, suggesting the existence of CY-sensitive suppressor cells. Similar conclusions

Fig. 1 Local GvH reaction in syngeneic host. Female BALB/c or AKR mice, 6–8-weeks old, were injected intraperitoneally with 125 mg kg⁻¹ cyclophosphamide (CY). Spleen cells were collected at various intervals. Cells from 6–12 spleens were pooled, suspended in Hanks BSS (supplemented with 5% foetal calf serum, 100 units ml⁻¹ penicillin, 100 µg ml⁻¹ streptomycin) and passed through a nylon wool column¹⁰. The eluted cells were washed three times with serum-free medium. As tested on cell smears stained with either Giemsa or with fluorescein-conjugated rabbit anti-mouse immunoglobulin, the nylon wool filtered cells were depleted on both phagocytic cells (less than 0.1%) as well as on B lymphocytes (less than 5%). In some experiments, nylon wool-filtered AKR spleen cells were incubated with anti-theta serum (C3H anti-AKR Thy-1.1 from Searle Diagnostic, High Wycombe, England) and guinea pig complement. Control cells were incubated with normal C3H serum and complement. After incubation, the cells were washed three times with serum-free medium. 3×10^6 cells in a volume of 0.05 ml were injected subcutaneously into the right hind footpad of a syngeneic recipient. Six days later, the draining and the contralateral lymph nodes were removed and weighed. The results are expressed as the ratio of the weights of stimulated to contralateral unstimulated popliteal lymph node. ●, Cells derived from CY-treated BALB/c donors. ○, Cells derived from untreated BALB/c controls. ★, Cells derived from CY-treated AKR donors and injected into AKR recipients. ▲, Cells derived from untreated AKR controls. ▲, Cells derived from CY-treated AKR donors after anti-theta treatment. Each value represents the mean \pm s.e.m. obtained from 5–7 recipients.

have been drawn by Röellinshoff *et al.*⁹, who observed induction of cytotoxic lymphocytes in mice to hapten-conjugated syngeneic cells after treatment with CY. We report here that injection of normal mice with CY results in manifestation of autoreactive T lymphocytes followed by the appearance of suppressor cells counteracting autoreactivity.

Balb/c or AKR mice were injected with a single dose of CY (125 mg kg⁻¹). At various time intervals splenic T cells (prepared by passing the cells through nylon-wool column¹⁰) were injected subcutaneously into the footpads of syngeneic recipients, and the resulting local graft versus host (GvH) reaction^{2,11} was determined in the draining lymph nodes. Autoreactive cells could be detected in the spleens of donors with a peak 6 d after CY treatment (Fig. 1). Autoreactive cells treated with anti-theta serum and complement failed to induce a GvH reaction. As in local GvH reactions induced by allogeneic cells^{12,13}, the GvH reaction in our syngeneic system depends on cells of host origin. This was shown by failure of X-irradiated (800 r) or CY-treated (125 mg kg⁻¹) recipients to give a GvH reaction when injected with autoreactive cells 1 d after this procedure. T cells derived from donors 8–9 d after CY treatment did not elicit a GvH reaction. Moreover, these cells, mixed with autoreactive cells, abolished the GvH reaction (Table 1), but if the donors were intravenously injected 20 h after CY with 5×10^7 syngeneic thymocytes autoreactive cells were not detectable. Splenic T cells of these animals collected 5 d after thymocyte injection suppressed the activity of autoreactive cells (data not shown), indicating CY-sensitivity of suppressor cell precursors.

It has been shown that T cells of neonatally⁴ or adult⁵ thymectomised mice injected into syngeneic recipients induce GvH reactions. The authors suggest that this phenomenon is due either to impaired thymus functions or loss of T-suppressor cells. This implies the coexistence of committed autoreactive and suppressor cells in normal spleen cell populations. Because suppressor cells are CY-sensitive, our results could be interpreted simply as being due to loss of suppressor cells, permitting detection of autoreactive cells; but the findings that normal spleen cells failed to inhibit expression of autoreactivity (Table 1) and that autoreactive cells do induce GvH reactions in normal syngeneic mice, argue against pre-existence of already committed suppressor cells. One of the crucial questions concerns the nature of self antigens which are recognised by the cells involved in this autoimmune phenomenon. Do autoreactive lymphocytes recognise normal or altered self-components, and what is the nature of the alteration? As previously shown¹⁴, mice injected with 125 mg kg⁻¹ CY are depleted (1–4 d after this treatment) of B cells and of subsets of T cells. The damage to the cells in the spleen is followed by a burst of rapidly proliferating B cells. B cell mitogens have been

Table 1 Demonstration of autoreactive lymphocytes and their suppression by regulatory cells

Treatment of donors	Nylon wool	No. of cells transferred	No. of recipients	Local GvH response lymph node ratio	
				Weight \pm s.e.m.	Cell number

c	yes	3×10^6	5	1.33 ± 0.37	1.69
d cells from a	yes	3×10^6			
+ normal spleen cells	yes	3×10^6	6	3.11 ± 0.30	4.09
d cells from a	yes	3×10^6			
+ cells from b	yes	1.5×10^6	6	1.38 ± 0.15	1.45
d cells from a	yes	3×10^6			
+ cells from b	yes	3×10^6	6	1.22 ± 0.11	1.07

Spleen cells were obtained from BALB/c donors as described in Fig. 1, for a, 6 d and b, 8 d after CY treatment; c, CY-treated donors were intravenously injected 20 h later with 5×10^7 normal thymocytes, spleens were removed 6 d after CY d, cells were mixed and injected in a volume of 0.05 ml into the hind footpad of the recipients. The results of the local GvH response are either calculated as the ratio in the weights \pm s.e.m. or as the ratio in the cell content between the stimulated and contralateral unstimulated lymph nodes 6 d after cell transfer. The ratios for the number of cells were obtained from pooled lymph nodes in each experimental group.

shown^{15,16} to induce the appearance of endogenous C-type RNA viruses in spleen cell culture supernatants and at the surface of splenic B cells. Therefore, it is possible that the 'autoreactive' T cells may recognise altered self antigens (possibly virus-altered) on proliferating B cells. This is supported by the findings that AKR mice, known to contain genetically much higher titres of endogenous ecotropic and xenotropic viruses¹⁷, when injected with CY, develop a greatly increased number of autoreactive cells, as compared to BALB/c mice.

The results indicate that CY treatment induces the appearance of 'new' antigenic sites (perhaps present at the surface of primitive B cells or as altered self-components due to endogenous virus induction) and the transient depletion of the spleen on T-suppressor cells. Both effects acting together permit manifestation of 'autoreactive' cells in normal animals.

Is there a circulating human thymic factor that induces cyclic AMP synthesis?

THE action of factors which have been extracted from the thymus or found circulating in peripheral blood and which are active in *in vitro* lymphocyte differentiation assays¹ has been extensively studied. Astaldi *et al.*² have described a factor (SF) of molecular weight (MW) less than 50,000 present in the serum of normal donors; a thymic site of production was suggested because it was not found in serum from athymic donors. It also significantly elevated cyclic AMP levels in mouse thymocytes. Because of the potential significance of this finding to the study of thymic factor action, we have attempted to corroborate these findings but, as reported here, we have observed that a serum fraction from both normal and athymic individuals can raise cyclic AMP levels in mouse thymocytes. Neither serum fraction, however, produced the degree of stimulation of cyclic AMP levels described by Astaldi *et al.*². Increases in cyclic AMP were much lower than those observed using the β -adrenergic agonist isoproterenol. We are therefore unable to confirm the existence of a circulating thymic factor in humans which raises cyclic AMP levels in mouse thymocytes.

Sera were initially obtained from two normal donors and two myasthenia gravis patients who had undergone thymectomy (samples by kind permission of Dr J. Posner, Memorial Hospital and Dr G. Jenkins, Mt Sinai Hospital, New York City). As described by Astaldi *et al.*², we separated the fresh serum into two fractions using Amicon CF50 filters. The fraction passing through the filter containing the SF (MW < 50,000)

was employed in the present studies. The fractionated SF samples were stored in aliquots at -20°C . Serum fractions from normal individuals were used after being stored for two days and fractions from athymic patients were used after two weeks' storage. As reported by Astaldi *et al.*², we observed that the serum fraction retained by the filter (MW > 50,000) was inactive in the assay used.

SF samples were evaluated for their ability to increase cyclic AMP levels of mouse thymocytes. Incubations were terminated either by rapid freezing and assayed for cyclic AMP *in situ* according to the procedure of Astaldi *et al.* ('unpurified' sample), or terminated by trichloroacetic acid precipitation followed by ether extraction and Dowex-1 column purification before assaying for cyclic AMP (ref. 3) ('purified' sample). Because the SF samples contained cyclic AMP (up to 50% of the total), the cyclic AMP levels of the serum were subtracted from the total cyclic AMP measured in the samples containing both cells and the factor, thus giving the net value provided by the cells. Basal cellular levels of cyclic AMP in the unpurified samples were 1.7 pmol per 20×10^6 cells and 2.8 pmol per 20×10^6 cells in purified samples (Table 1). Total cyclic AMP levels were increased in a dose-dependent manner by both normal and athymic SF, but when the cyclic AMP component of the SF was subtracted, cellular increases were marginal and inconsistent in samples assayed by the procedure of Astaldi *et al.*². In purified samples, however, both normal and athymic SF's stimulated cyclic AMP levels in a dose-dependent fashion by up to two and a half times. These increases were small in comparison with the stimulatory effect of isoproterenol (Table 1 and refs 2, 4).

Manipulation of the thymocytes or of the SF's did not change their effects on cyclic AMP levels. Thus, serum fractions prepared from normal donors by rapid defibrination of whole blood followed by immediate transfer to an ice bath at 4°C produced no greater enhancement of cyclic AMP levels in thymocytes than those prepared by allowing whole blood to

Table 1 Effects of athymic and normal serum fractions on mouse thymocyte cyclic AMP levels

Addition		Unpurified sample		Purified sample	
		Total cyclic AMP	Net cyclic AMP	Total cyclic AMP	Net cyclic AMP
Normal SF	0	1.70	1.70	2.84	2.84
	0.125 ml	2.26	1.50	4.21	3.17
	0.25 ml	3.73	2.20	7.21	5.12
	0.50 ml	4.70	1.64	10.99	6.83
	0.25 ml	1.53	0	2.08	0
Athymic SF	0	1.70	1.70	2.84	2.84
	0.125 ml	2.96	2.28	4.89	3.97
	0.25 ml	3.56	2.20	6.21	4.36
	0.50 ml	4.99	2.27	10.36	6.66
	0.25 ml	1.36	0	1.85	0
10 ⁻⁵ M Isoproterenol		+		185.6	185.6

Serum fractions of less than 50,000 MW were prepared from two normal and two athymic donors as described by Astaldi *et al.*². Thymocytes were obtained from 6-10-week female C57BL/6 mice and resuspended in triplicate in Hank's Balanced Salt Solution without phenol red. Each tube contained 20×10^6 cells. 0.125, 0.25 or 0.5 ml aliquots of the serum fractions were added to make a total volume of 1 ml per tube. After incubating for 5 min at 37°C , the incubation was either terminated by rapid freezing and assayed for cyclic AMP *in situ* as previously described by Astaldi *et al.*², or terminated by trichloroacetic acid precipitation followed by ether extraction and Dowex-1 column purification before assaying for cyclic AMP (ref. 3). Aliquots of purified samples were tested with a phosphodiesterase preparation. >95% of the cyclic AMP measured was destroyed by this treatment, confirming the purity of the material. Results are expressed as pmol cyclic AMP measured per 20×10^6 cells. 'Total cyclic AMP' is the total amount of cyclic AMP measured, 'Net cyclic AMP' has the cyclic AMP content of the SF subtracted out, so that the values reflect only cell-produced cyclic AMP.

clot. Moreover, neither basal nor stimulated levels of cyclic AMP were affected by pretreating the thymocytes on nylon wool columns.

Table 1 shows that both total and net cellular cyclic AMP levels (basal and stimulated) are much higher after sample purification, suggesting that there may be factors in the unpurified material which interfere with the cyclic AMP assay. We have previously found that such factors must be removed by Dowex-1 chromatography before accurate cyclic nucleotide measurements can be made³. Phosphodiesterase treatment confirmed that our purified samples after Dowex chromatography were >95% cyclic AMP. It is possible that Astaldi *et al.* were not measuring true cyclic AMP levels, but rather some other as yet unknown contaminating material. All our subsequent data were obtained by isolating and purifying cyclic AMP from the sample after acid precipitation.

Our results differ from those of Astaldi *et al.*² in that their basal levels of cyclic AMP were higher than ours (10 compared to our 2.8 pmol per 20×10^6 cells). Our values are in close agreement with those obtained by others^{4,5}. Moreover, although we have also observed that stimulation with SF is dose-dependent, we have observed much lower stimulated levels and smaller net increase in cyclic AMP than did Astaldi *et al.* The reason for these discrepancies remains unknown. Differences may in part relate to the relative health of the cells employed, failure to calculate cyclic AMP levels in the SF sample and to subtract it from the total, and possible difficulties in measuring cyclic AMP in unpurified samples.

Our preliminary evidence also indicated that both normal and athymic serum fractions exhibited almost identical dose-dependent elevations of cyclic AMP levels in contrast to the findings of Astaldi *et al.*² whose serum fractions from athymic patients were without effect on cyclic AMP levels in thymocytes. We therefore prepared SF's from a further seven patients who had undergone thymectomy following treatment for myasthenia gravis (age range 26–54 yr; time post-thymectomy 3 months to 12 years 3 months). The effect on mouse thymocytes of the serum fractions from eight of the nine athymic patients is shown in Table 2, and compared with the effects of identical fractions prepared from three normal donors.

SF's were assayed either the day they were prepared or after being stored for 24 h at -20°C . Samples were stored in aliquots at -20°C and retested at intervals over a period of up to two months. Although variations in cyclic AMP elevation were observed over this period with individual SF's, there was no correlation between the level of cyclic AMP induced and sample storage time. It is apparent from Table 2 that the levels of cyclic AMP induced by serum fractions from athymic patients are almost identical to those induced by fractions from normal donors. SF from only one athymic patient failed to induce increases in cyclic AMP. Although the treatment of this patient was not appreciably different from that of the eight others, her clinical state was one of the most serious despite thymectomy. This suggests that lack of a thymus may not be central and that the patient may be deficient in some other circulating endocrine product which could raise cyclic AMP levels.

Table 2 Effects of serum fractions prepared from normal and athymic human donors on cyclic AMP levels in mouse thymocytes

Serum fraction volume	Normal	Athymic
0	1.00	1.00
0.125 ml	1.61 ± 0.27 (9)	1.76 ± 0.13 (12)
0.25 ml	2.16 ± 0.35 (9)	2.93 ± 0.29 (10)
0.50 ml	4.30 ± 2.04 (6)	4.66 ± 1.05 (5)

Results are expressed as stimulation with regard to control \pm s.e.m. (no. of separate determinations). Cyclic AMP present in each serum volume was subtracted from total cyclic AMP measured. Experimental conditions as in legend to Table 1. Basal levels of cyclic AMP; 3.6 ± 0.4 pmol per 20×10^6 cells.

Our observations are at variance with the findings of Astaldi *et al.*² who reported that serum fractions from 18 out of 18 athymic donors could not elevate cyclic AMP levels in mouse thymocytes. We suggest that a cyclic AMP-raising material is present in the serum and that the severity of illness rather than the absence of a thymus may determine whether the factor is present in serum. In any case, we consider it more probable that the factor is synthesised outside the thymus, and is in no way related to circulating thymic factors⁶ the activity of which has been shown to decrease with time after thymectomy in experimental animals. Several circulating products, such as prostaglandins or adrenaline, with known cyclic AMP-raising properties in lymphocytes, may be likely candidates and defects in the secretion of one of these substances may account for the single athymic donor not showing cyclic AMP-raising activity in her serum.

In summary, we could find no evidence for a serum substance dependent on the presence of a thymus and acting to stimulate cyclic AMP synthesis in mouse thymocytes. We suggest that the rise in cyclic AMP in mouse thymocytes is due to a non-thymic, circulating material.

We thank Paul Schulman for technical assistance and Dr G. Goldstein for stimulating discussion.

A. ASTALDI, G. C. B. ASTALDI, P. TH. A. SCHELLELKENS AND V. P. EIJSSVOOGEL REPLY—To date, we have investigated sera from 56 thymectomised myasthenic patients (mean age 32.1 yr, s.e.m. ± 1.8 , time post-thymectomy 1 month to 19 yr), 37 non-thymectomised myasthenic patients (mean age 44.8 yr, s.e.m. ± 3.4) and 87 normal healthy individuals (mean age 29.0 yr, s.e.m. ± 1.2). The SF activity was very low in the thymectomised donors (mean 15.6 pmol cyclic AMP per 2×10^7 cells, s.e.m. ± 3.1), but consistently demonstrable both in normal healthy individuals (mean 76.9 pmol cyclic AMP per 2×10^7 cells, s.e.m. ± 4.0) and in non-thymectomised myasthenic patients (mean 56.0 pmol cyclic AMP per 2×10^7 cells, s.e.m. ± 7.4). The difference in SF activity between normals and non-thymectomised myasthenic patients is probably due to age, because we observe that the level of SF declines progressively after the age of 30. Interestingly, within the group of the thymectomised donors two populations could be distinguished, a major one ($n = 43$) with almost no SF activity (mean 6.0 pmol cyclic AMP per 2×10^7 cells, s.e.m. ± 1.1) and a minor one ($n = 13$) with SF activity (mean 47.0 pmol cyclic AMP per 2×10^7 cells, s.e.m. ± 7.6) which is closer to that in control groups. This finding is not unexpected in view of the well known 20% incidence of ectopic thymus in humans^{1,2}; also, in some patients the thymectomy may have been incomplete. Repeated determinations of SF activity before and after thymectomy revealed that the SF activity in humans decreases dramatically after thymectomy (Fig. 1).

Sunshine *et al.* state that the cyclic AMP present in the SF should be subtracted from cyclic AMP measured in the samples after incubation. The assay method that we use, however, (see legend to Fig. 1) is rather different from that of Sunshine *et al.* Contrary to their assay, we are measuring only the net cellular cyclic AMP, for by washing the cells before the extraction of cyclic AMP, any cyclic AMP present outside the cells is removed. This could be further sustained by the finding

Fig. 1 SF activity at different time intervals before and after thymectomy (mean \pm s.e.m. of seven myasthenic patients). Human blood was collected and immediately defibrinated by shaking for 8–10 min with glass beads. The defibrinated blood was immediately transferred to a plastic tube kept in melting ice and centrifuged at $+4^\circ\text{C}$ for 15 min at 600g in order to obtain serum. Seven ml of serum was immediately filtered through an Amicon Centrifo CF 50 A filter (MW cut-off 50,000). Filters were centrifuged at $+4^\circ\text{C}$ for 1 h at 600g. The ultrafiltrate (SF) was divided into appropriate aliquots, frozen at -100°C and lyophilised. All samples were processed in the same way and tested within a month. We demonstrated that, once lyophilised, samples retain SF activity for a period of over 8 months. Cyclic AMP-free and prostaglandin-free SF was obtained by means of Bio-Rad AG1-X8 chromatography. SF was eluted with 0.1 N formic acid and relyophilised. As control we used SF diluted with 0.1 N formic acid and relyophilised without chromatography. Lyophilised material was reconstituted, just before assay, to the original volume of the filtrate with distilled water. Thymocytes were obtained from C57BL/6 mice aged 6–8 weeks by means of organ dissociation through a metal sieve and subsequent filtration through nylon wool columns. Each assay tube contained 2.5 ml SF, 2.5 ml Earle's solution and 10^7 thymocytes. After 5 min of incubation at 37°C , the tubes containing the cell suspension were centrifuged at $+4^\circ\text{C}$ for 5 min at 600g. Cell viability, both before and after incubation, was $>95\%$. The supernatant was discarded and the pellet resuspended in 0.5 ml of 50 mM Tris-HCl, 4 mM EDTA buffer, pH 7.5, by means of a vortex mixer. Tubes were placed in liquid nitrogen for 1 min and subsequently in a boiling water bath for 2–3 min. Coagulated proteins were spun down at $+4^\circ\text{C}$ for 5 min at 1,500g. The supernatant was directly assayed for cyclic AMP as described⁹ or further purified by means of Bio-Rad AG1-X8 chromatography. Cyclic AMP was eluted with 2N formic acid according to the method of Kuehl *et al.*³. Results were expressed in picomoles of cyclic AMP per 2×10^7 cells. Values reported here were obtained by subtracting the background cellular levels of cyclic AMP (that is, the level of cyclic AMP in thymocytes incubating as such).

that cyclic AMP-free SF (after Bio-Rad AG1-X8 chromatography) had activity similar to SF prepared without chromatography.

Sunshine *et al.* suggested that we might be measuring material other than cyclic AMP, but phosphodiesterase treatment of extracted cellular cyclic AMP confirmed that the material measured was $>90\%$ cyclic AMP. The presence of inhibitory factors is very unlikely because, when a known amount of reference cyclic AMP was added to the extracted cellular cyclic AMP, we recovered $>95\%$ of the expected value, again indicating the correctness of our cyclic AMP measurements. We have purified the extracted cellular cyclic AMP by means of ion exchange chromatography as reported by Kuehl *et al.*³ without any effect on the significance of our findings. In addition, the values of cyclic AMP that we measured in unpurified samples essentially agree with those observed by others⁴, both for isoproterenol and prostaglandin E_1 -stimulated lymphoid cells.

A further discrepancy between the results of Sunshine *et al.* and ourselves is the great difference in activity that we observed between SF prepared by rapid defibrination of fresh blood and SF obtained from blood just allowed to clot; when blood from

normal donors was allowed to clot at room temperature for 1 h, we could find almost no SF activity (mean 6.2 pmol cyclic AMP per 2×10^7 cells, s.e.m. ± 1.2 , $n = 9$). This value is similar to those reported by Sunshine *et al.*, which we regard as very low. It should be stressed that active SF preparations can only be obtained if the extraction procedure described by us is exactly followed, including rapid defibrination.

Sunshine *et al.* raised the possibility that the SF activity might be due to adrenaline or prostaglandins. This is very unlikely in view of the target cell specificity of SF as compared to the β -adrenergic stimulator isoproterenol and to prostaglandin E_1 ⁵. Hadden *et al.*⁶ demonstrated the presence of adrenergic receptors in human lymphocytes and Smith *et al.*⁷ showed that prostaglandins and β -adrenergic stimulators increase cellular cyclic AMP in human peripheral blood lymphocytes, while α -adrenergic stimulators do not. According to this view, adrenaline should stimulate cyclic AMP by means of interaction with the β -adrenergic receptors. We found⁵ that SF does not increase cyclic AMP levels in human peripheral blood lymphocytes. This rules out the possibility that the SF activity might be due to adrenaline or prostaglandins. We also reported⁵ that the β -adrenergic inhibitor propranolol does not to any extent inhibit the SF activity, indicating that SF is not acting on the β -adrenergic receptors.

We have demonstrated⁸ that the target cells for SF are among the hydrocortisone (HC)-sensitive thymocytes and that SF induced HC resistance, a maturation step reported to be induced also by a thymic extract⁹ and by a circulating thymic factor¹⁰. When mouse thymus was depleted of HC-sensitive cells by means of HC treatment *in vivo*, we found that cells recovered (HC-resistant) could not be stimulated to increase their cyclic AMP level by SF. On the contrary, prostaglandin E_1 induced HC-resistant cells to increase cyclic AMP at a level similar to that found when the total thymic population was used as prostaglandin target, again indicating that SF is not acting on the prostaglandin receptor. This could be further supported by the finding that prostaglandin-free SF (after Bio-Rad AG1-X8 chromatography) had activity similar to SF prepared without chromatography.

Finally, we found (Schellekens *et al.*, in preparation) that SF activity was almost absent in seven children with thymic-dependent immunodeficiencies and present in four children with severe combined immunodeficiency disease. Three children, almost completely lacking in SF activity, were treated with the partially purified thymic extract, thymosin fraction V, prepared by Hoffmann-La Roche according to Hooper *et al.*¹¹ Shortly after initiation of thymosin treatment, we observed¹² the appearance in the patients' blood of SF or SF-like cyclic AMP increasing activity. This activity disappeared after thymosin was stopped in one patient. Since thymosin does not induce cyclic AMP increase when tested directly on mouse thymocytes *in vitro*¹³, the SF (-like) activity found during thymosin treatment might be due to *in vivo* activation either of or by thymosin.

The only remaining possible explanation for the failure of Sunshine *et al.* to reproduce our findings seems to be the difference in technique. We realise that the description of methodology previously reported⁵ could be misinterpreted. In fact, as stated above, non-appropriate handling of the blood may cause loss of SF activity. When tested, such SF will give a very modest cyclic AMP stimulation in the range of values reported by us for thymectomised donors (ref. 5 and above), which is of exactly the same order of magnitude as that reported by Sunshine *et al.* both for normals and thymectomised individuals.

Fibroblast-conditioned medium contains cell surface proteins required for cell attachment and spreading

PROLIFERATION in diploid fibroblasts is limited to cells that are attached and spread on a substrate. The attachment and spreading activities of normal cells are enhanced in the presence of media conditioned by the growth of diploid fibroblasts^{1,2}, and a cell surface protein (LETS/CSP)³ extracted from normal cells enhances the attachment of transformed cells^{4,5}. We report here that the activities present in conditioned medium are due to several high molecular weight glycoproteins ('released proteins'). In addition, we find that the same activities can be extracted ('extracted proteins') from the surfaces of whole cells. The results establish that growth related biological activities are transferred intercellularly through the release and absorption of cell surface components.

A comparison of released and extracted proteins is shown in Fig. 1. Figure 1a and e show that approximately 90% of the Coomassie blue staining material was located in three major bands of >150,000 apparent molecular weight (MW). The rest of the material migrated between 35,000 and 150,000 MW and was removed in the supernatant fraction after treatment with a 35% saturated solution of ammonium sulphate. The three released proteins were clearly the products of cellular synthesis. Metabolic incorporation of either ¹⁴C-leucine (Fig. 1f–h) or ¹⁴C-glucosamine (Fig. 1j) labelled all major bands. The labelling patterns of the extracted proteins (Fig. 1i and k) were similar. The band in the middle of the gels, stained with Coomassie blue (Fig. 1a, e), comigrates with bovine serum albumin and probably represents a serum contamination in those preparations. That protein is not present in the final preparations, however (Fig. 1c). In addition, the incorporation of both precursors indicated that the major bands contained both carbohydrate and protein. Colorimetric analysis of the protein mixtures by the Lowry test for protein⁶ and by a phenolsulphuric acid test for carbohydrate⁷ revealed a protein to carbohydrate mass ratio of about 10:1. These criteria suggested that the bands were composed of glycoproteins.

The similarities in the electrophoretic patterns suggested that released and extracted proteins were the same proteins and that the released proteins were components of the cell surface. That conclusion was supported by labelling whole cells with radioiodine using a lactoperoxidase system⁸ to ensure that only external components were radioactive. The electrophoretic pattern of proteins extracted from iodinated cells is shown in Fig. 1m. A duplicate culture of iodinated cells was washed to remove loosely attached peripheral components⁹ and incubated for 24 h. The iodinated released proteins (Fig. 1l) showed the same major bands as observed for extracted proteins. There were extra minor bands in the released protein fraction. The origin of those components is unknown.

Both extracted proteins and released proteins promoted the attachment and spreading of non-transformed cells. Table 1 shows the results of experiments in which low density cells were plated on glass in the absence of serum.

In these conditions very few cells attached and no cells had extended processes. The addition of bovine serum albumin 50 µg ml⁻¹ had no effect. However, the addition of 50 µg ml⁻¹ of extracted or released proteins resulted in > 90% of the cells spread within 20 h. The partial fractionation of the released and extracted proteins by ammonium sulphate precipitation showed that the activity was present in material that precipitates in a solution that is less than 35% saturated and that most of the activity is in the 20–35% saturated fraction (Table 1). Although this fractionation procedure is imperfect, it is reasonable to conclude that the spreading and attachment activities were associated with the presence of high molecular weight species. We were unable to detect any low molecular weight

Fig. 1 Comparison of released and extracted proteins. All experiments used a single primary culture of human diploid fibroblasts that was derived from a foreskin biopsy and initiated in this laboratory. The cells were cultured in medium 199 (GIBCO) supplemented with 20% foetal bovine serum (Flow) and antibiotics. Released proteins were obtained as described previously¹. Extracted proteins were obtained by the method developed for chick cell surface proteins¹⁵ using 1 M urea. To obtain ¹⁴C-labelled proteins, confluent monolayers were pulsed for 24 h with 0.3–0.5 µCi ml⁻¹ ¹⁴C-amino acids (280 mCi mmol⁻¹) or ¹⁴C-glucosamine (60 mCi mmol⁻¹) (New England Nuclear). The monolayers were then washed to remove all traces of serum and the medium was replaced with serum-free medium 199 containing 0.3–0.5 µCi ml⁻¹ of the same labelled compound. After 24 h the released proteins were gently decanted and the cells were washed. Proteins were then extracted from the washed cells. ¹²⁵I-labelled released proteins were obtained by labelling a washed monolayer for 2 min with 500 µCi ml⁻¹ sodium iodide (NEN) using a lactoperoxidase-catalysed procedure⁸. The labelled cells were then incubated for 7–20 h, in serum-free medium 199. Electrophoretic separation of dithiothreitol-reduced samples was obtained by standard procedures¹⁶. Samples were heat denatured in 0.1% sodium dodecyl sulphate (SDS) and electrophoresed through a 5% polyacrylamide stacking gel (not shown) and a 7.5% polyacrylamide separating gel. This figure is a composite of several experiments performed at different times. Autoradiograms of the gels (tracks g–m) were obtained by exposing prefogged Kodak X-ray film to dried gels for 3–21 d at –60 °C. Protein concentrations in the 13 tracks range from 40 to 250 µg. Tracks a–e: Coomassie blue stained: a, released protein; b, 20% (NH₄)₂SO₄ released protein; c, 35% (NH₄)₂SO₄ released protein; d, 70% (NH₄)₂SO₄ released protein, and e, extracted protein. Tracks f–i: ¹⁴C-amino acid labelled: f, 20% (NH₄)₂SO₄ released protein; g, released protein; h, 70% (NH₄)₂SO₄ released protein, and i, 35% (NH₄)₂SO₄ extracted protein. Tracks j, k: ¹⁴C-glucosamine labelled: j, released protein and k, extracted protein. Tracks l and m: ¹²⁵I-labelled: l, released protein and m, extracted proteins. The three major bands near the top of the gels (shown most clearly in (c)) have apparent molecular weights > 150,000. The abbreviation AMS indicates that the protein was insoluble in the stated concentration of ammonium sulphate.

Table 1 Spreading activity of released and extracted proteins

Sample	No. of cells		% Spread
	Attached	Spread	
Control	7	0	0
+ BSA	6	0	0
Released proteins	2	98	98
20% (NH ₄) ₂ SO ₄	28	27	49
35% (NH ₄) ₂ SO ₄	34	102	75
70% (NH ₄) ₂ SO ₄	9	1	10
Extracted proteins	4	98	96
35% (NH ₄) ₂ SO ₄	7	96	93

All numbers represent the means of at least two independent determinations. The control is medium 199 without protein. All other samples contain 35–45 µg of protein in medium 199. Released and extracted proteins were precipitated sequentially with 20%, 35%, and 70% saturated ammonium sulphate solutions at 0 °C. Attached and spread cells are determined by phase contrast microscopy according to the parameters suggested by Taylor¹⁷.

species on either 7.5% or 20% polyacrylamide gels (data not shown) even at concentrations as high as 5 mg ml⁻¹ (50 µg ml⁻¹ is required for > 95% spreading). Electrophoretic profiles of ammonium sulphate-precipitated materials (Fig. 1 *b–d, f–h*) indicated that the 20–35% fraction contained the three high molecular weight species.

The data may be interpreted as indicating either that the spreading activity and the attachment activity were due to separate components or that one protein promotes both activities at high concentration and only attachment at low concentrations. Table 2 shows that over 50% of the spreading activity was absorbed to fixed cells, but that cell attachment was unaffected by absorption. Trypsin-treated cells were washed and fixed before absorption to prevent the production and release of the proteins under investigation. The spreading activity was substantially reduced in the absorbed solution, but the total number of attached plus spread cells remained about the same for absorbed material as it was for non-absorbed material. Other experiments using radioactive released proteins showed that in the conditions of these experiments the proteins absorbed to the cells and not to the plastic container (data not shown). The data presented here show that cell surface components are active in cell attachment and spreading and that those components are released, in an active form, into the culture media. The function of that turnover is not known, however. We propose that the release and absorption of cell-surface components is a form of intercellular communication that promotes cell growth. Previously, we demonstrated

that cells plated at high density attached and spread in the absence of serum while low density cells required non-dialysable components present in conditioned medium¹. We suggest that at high density the concentration of cell surface-derived released proteins is high enough to maintain a critical concentration of those proteins on the cell surface. However, at low density, the equilibrium between the concentration of released proteins on the cell surface and in the culture medium is shifted so that the surface concentration is too low to support attachment and spreading. It is possible that the low-density cells have an altered physiology¹⁰, but our experiments do not test this.

We do not know which of the released proteins are responsible for the activities tested. However, the involvement of cell-surface components in cell adhesion is well established. A LETS/CSP protein has been shown to be active in red cell agglutination¹¹ and in the adhesion of transformed cells^{1,5}. In addition, there is considerable evidence to indicate that cell-membrane components are released into the culture media^{12,13} and that a serum component is antigenically identical to LETS/CSP¹⁴. It is possible that the large band at the top of the gel is identical to LETS/CSP³ and is responsible for some of the activity. However, it is also possible that more than one protein is involved since attachment and spreading activities seem to be due to separate components (Table 2).

Table 2 Absorption of released protein spreading activity

Sample	Attached + spread = total			% Spread
Control	8	0	8	0
Released protein (50 µg ml ⁻¹)	3	100	103	97
Absorbed solution	60	49	109	45
Released protein (25 µg ml ⁻¹)	31	58	89	65
Absorbed solution	80	27	107	25

Values represent the means of two determinations per sample. Absorption procedure: released proteins were absorbed to whole fixed cells by incubating a cell suspension (1.8 × 10⁷ cells per ml of 50 µg released protein) for 10 min at 37 °C. After the incubation the mixture was centrifuged to pellet the cells and the supernatant fraction retained as the 'absorbed solution'. The cells used for absorption had been treated with 50 µg ml⁻¹ trypsin solution for 10 min at 37 °C and subsequently fixed in 3% formaldehyde. Fixed cells were washed extensively and used without further delay. Residual proteolytic activity was not detected.

Calcium effects on gap junction structure and cell coupling

PROTOPLASMIC molecules of low molecular weight are known to travel freely across the boundaries between most neighbouring cells through small intercellular channels generally thought to be at the intramembranous particles of gap junctions^{1–3}. The permeability of the channels can be decreased to a complete interruption of cell communication by a variety of treatments^{2–10}. Most of these treatments raise the concentration of ionised calcium, [Ca²⁺], in the cytoplasm⁶, suggesting that calcium may be the uncoupling agent in both vertebrate⁹ and invertebrate cells^{2,8}. In some systems glutaraldehyde fixation has also been shown to produce uncoupling³; however, this type of uncoupling does not seem to be triggered by calcium¹⁰. In parallel with functional uncoupling reversible structural changes have been described in gap junctions of crayfish characterised by an increase in tightness and regularity of particle aggregation

and a decrease in junctional thickness and particle size¹⁰. These changes, interpreted as reflecting conformational rearrangements in the protein framework of the channels resulting in channel obliteration, were recently confirmed in the rat¹¹ although in the latter, functional uncoupling was not measured electrophysiologically, but only presumed on the basis of reasonable comparative arguments. It remains uncertain whether or not the changes in both the gap junction structure and the cell coupling are due to a direct action of calcium on the junctional membranes. We show here that the junctional change is indeed a calcium effect, triggered by $[Ca^{2+}]$ as low as 5×10^{-7} M.

Gap junctions of the eye lens of calf were studied by freeze-fracture either in intact cells or in isolated preparations. The lenses were dissected from the eyes 30–60 min after death. For experiments on intact cells the lenses were fixed in glutaraldehyde, infiltrated with glycerol (as cryoprotective agent) and processed for freeze-fracture as described elsewhere¹¹. In these preparations, gap junctions between epithelial cells of the anterior lens surface showed particles and complementary pits organised in regular hexagonal arrays with unit cells of ~ 8.5 nm (Fig. 1a), the crystallinity of the array being more pronounced in the pitted face, as described in other gap junctions¹², while gap junctions between fibre cells displayed particles and pits irregularly packed at various spacings (Fig. 1b). This difference, reported also by Benedetti *et al.*¹³ is probably a consequence of the difference in metabolic properties between epithelial and fibre cells. The tightly and regularly packed epithelial junctions are identical to rat liver and stomach junctions uncoupled by inhibitors of the metabolism and are likely to be in an uncoupled state as well, since the lens epithelium, known to possess an active oxidative metabolism¹⁴, is expected to suffer the effects of severe hypoxia if it is not fixed immediately after animal death. In fact the inhibition of the metabolism and the consequential depletion of energy stores caused by hypoxia¹⁵ are known to raise the cytoplasmic $[Ca^{2+}]$ and result in cell uncoupling⁸ as Ca^{2+} diffuses in the cytosol from the mitochondria and the surface membrane¹⁶. Fibre cells, on the other hand, derive their energy requirement from glycolytic metabolism¹⁴ and therefore are rather insensitive to hypoxia; this is probably the reason that their gap junctions display structural characteristics of normally coupled junctions.

For studies on isolated fibre cell junctions, eight to ten lenses per experiment were homogenised either in sodium bicarbonate buffer (1×10^{-3} M, $pH = 7.4$) or in the same buffer containing EDTA 1×10^{-2} M to chelate divalent cations. The homogenate was washed four times in bicarbonate or bicarbonate-EDTA buffer respectively, centrifuged to a pellet and freeze-fractured after glutaraldehyde fixation and cryoprotective treatment. Due to the great number of gap junctions between fibre cells, the

Fig. 1 Freeze-fracture replicas of gap junctions in intact cells of calf lens. *a*, Gap junction between epithelial cells of the anterior lens surface. Particles and complementary pits form a regularly hexagonal array with a unit cell of ~ 8.5 nm. *b*, Gap junction between fibre cells. Particles and pits are randomly distributed at variable spacings. P, face P (protoplasmic membrane leaflet); E, face E (exoplasmic membrane leaflet). ($\times 160,000$).

Fig. 2 Freeze-fracture replicas of gap junctions isolated from fibre cells of calf lens. *a*, Junction isolated in absence of EDTA. *b*, Junction isolated in absence of EDTA and subsequently incubated in 3×10^{-3} M EGTA. *c*, Junction isolated in presence of 1×10^{-2} M EDTA. *d*, Junction isolated in presence of 1×10^{-2} M EDTA and subsequently incubated in a 1×10^{-3} M calcium solution. Notice that junction isolation in absence of chelators of divalent cations causes aggregation of junctional particles into tight hexagonal arrays with unit cells of 7–8 nm (*a*). The phenomenon is not reversed by EGTA (*b*) or EDTA treatment, but can be prevented if the junctions are isolated in presence of EDTA (*c*). Exposure of junctions isolated in EDTA to calcium solutions causes hexagonal packing of the junctional particles (*d*). P, face P; E, face E. ($\times 160,000$).

crude pellets obtained are sufficiently rich in junctions not to require detergent treatment, and thus offer an excellent source of relatively undamaged gap junctions. Junctions isolated without EDTA display particles and pits tightly and regularly packed into hexagonal arrays with unit cells of 7–8 nm (Fig. 2a) while junctions isolated in bicarbonate-EDTA buffers have particles and pits loosely and irregularly aggregated (Fig. 2c). If junctions isolated in the presence of EDTA are suspended for 30 min at $37^\circ C$ in calcium solutions (1×10^{-5} – 3×10^{-3} M), buffered to $pH 7.4$ with 1×10^{-3} M Tris, particles and pits aggregate tightly into regular hexagonal arrays (Fig. 2d). Control junctions, suspended for the same length of time and at the same temperature in 1×10^{-2} M EDTA solutions ($pH = 7.4$) maintain the irregularly and loosely packed particle arrays (same as Fig. 2c). Junctions treated with calcium solutions do not recover the control appearance if they are subsequently exposed to 1×10^{-2} M solutions of EDTA or 3×10^{-3} M EGTA (Fig. 2b).

In junctions with regular hexagonal arrays the particles are ~ 1 nm smaller than in the others and appear more homogeneous in size and shape. In addition, in these junctions the fracture plane tends to remain within the same membrane, while in the irregularly packed junctions it steps frequently up and down from one to the other membrane. In most junctions there are a few particles which fracture away with the external leaflet, appearing as bumps on face E (Figs 2, 3). Particles on the pitted face of gap junctions are uncommon in vertebrates but are frequent in crayfish¹⁷; in the rat they are a common feature of gap junctions of livers perfused with hypertonic sucrose¹¹.

The finding of hexagonal particle packings in fibre cell junctions isolated in the absence of EDTA (Fig. 2a) suggested that trace amounts of divalent cations may be sufficient to cause the particle-clumping phenomenon. Therefore experiments using

EDTA-calcium buffers were performed in an attempt to define the triggering $[Ca^{2+}]$. Junctions isolated in bicarbonate-EDTA solutions, as previously described, were incubated for 30–120 min at 37 °C in calcium-EDTA solutions in which $[Ca^{2+}]$ was buffered to different levels ranging from $1 \times 10^{-8} M$ to $1 \times 10^{-6} M$. Calcium-EDTA solutions were prepared by dissolving calculated amounts of $CaCl_2$ into $1 \times 10^{-2} M$ solutions of EDTA buffered to pH 7 with $2 \times 10^{-2} M$ HEPES (Sigma). The amounts of $CaCl_2$ to be added were calculated using an EDTA dissociation constant for calcium of $5 \times 10^{-8} M$ (at pH 7, $\log K = 7.3$) (ref. 18). The following equation was used:

$$[Ca^{2+}]_f = ([Ca^{2+}]_t[EDTA]_t + [Ca^{2+}]_f^2 + [Ca^{2+}]_f K_D) / (K_D + [Ca^{2+}]_f)$$

where $[Ca^{2+}]_t$ represents the amount of total calcium per unit volume of medium, which gives a concentration of free calcium, $[Ca^{2+}]_f$, when the total amount of EDTA per unit volume of medium is $[EDTA]_t$, and K_D is the dissociation constant of the reaction: $Ca + EDTA \rightleftharpoons Ca-EDTA$. In each experiment the junctions were washed, before incubation, in the same calcium-EDTA solution to be used for incubation, so that residual amounts of EDTA left in the same sample after the preliminary isolation procedure would not interfere with the EDTA-calcium buffers. To make certain that changes in pH did not take place during incubation, the pH of the solutions was measured both at the beginning and at the end of the incubation period. No effect was detected on the structure of the junctions with solutions in which the $[Ca^{2+}]$ was buffered to values ranging from $1 \times 10^{-8} M$ to $3 \times 10^{-7} M$ (Fig. 3a, b), while solutions of $5 \times 10^{-7} M$ (Fig. 3c) or greater (Fig. 3d) $[Ca^{2+}]$ consistently caused the junctional particles and pits to aggregate tightly into regular hexagonal arrays. 89.3% of all the junctions exposed to $[Ca^{2+}]$ greater than $5 \times 10^{-7} M$ showed hexagonal particle packing (13 experiments were performed and 131 junctions were photographed), and 99% of all the junctions exposed to $[Ca^{2+}]$ lower than $5 \times 10^{-7} M$ showed

irregular particle packing (11 experiments were performed and 114 junctions were photographed). Interestingly, the threshold of intracellular $[Ca^{2+}]$ for functional uncoupling is believed to be somewhere between $1 \times 10^{-7} M$ and $5 \times 10^{-8} M$ in salivary gland cells of insect larvae^{19,20} and slightly larger than $2 \times 10^{-7} M$ in cow and calf heart muscle²¹ (because of the close relationship between the onset of uncoupling and the onset of muscle tension) which fits reasonably well with $5 \times 10^{-7} M$ $[Ca^{2+}]$ obtained for the changes in gap junction structure.

In conclusion, the exposure of isolated gap junctions to $5 \times 10^{-7} M$ or greater $[Ca^{2+}]$ affects the junctional structure similarly to uncoupling treatments performed on intact cells. Since uncoupling is believed to be triggered by an increase in $[Ca^{2+}]$ in the cytoplasm, the calcium dependent changes in gap junction structure described here confirm the hypothesis^{10,11} that gap junctions with tightly packed hexagonal arrays of particles correspond to non-permeable junctions and indicate that calcium affects both the structure of the junctions and the cell coupling by acting directly on the junctional molecules. These data also suggest that small fluctuations from the normal intracellular $[Ca^{2+}]$, believed to be $1 \times 10^{-7} M$ (ref. 16), could be sufficient to produce functional uncoupling. Our findings do not, however, necessarily indicate that calcium is indeed the only agent capable of triggering the junctional changes with uncoupling. A recent report²² suggesting the uncoupling effects of low pH poses the question as to whether or not the structure of the junctions can also be affected in a similar way by acidic free calcium solutions. Experiments using such solutions are underway. Evidence from ultrastructure^{10,11} and X-ray diffraction^{23,24} suggests that the structural change is not a mere modification in particle packing but rather a conformational rearrangement in the molecular framework of the channels. The mechanism that causes the rearrangements in particle array is not known; however, it is interesting that it is triggered by a $[Ca^{2+}]$ similar to that²⁵ which causes muscle contraction. Although the presence of an actomyosin-like system associated with gap junction membranes has never been suggested, there are no reasons for discarding it *a priori*.

Effects of fusogenic agent on membrane structure of erythrocyte ghosts and the mechanism of membrane fusion

MEMBRANE fusion clearly requires that participating lipids assume some transitory non-bilayer configuration during the intermediate stages. Previous workers have suggested that intermediate micellar¹ or inverted micellar^{2,3} structures may occur, but the precise nature of possible intermediates and their relation to the physical properties of membrane lipids are obscure. In this regard, Lucy and co-workers⁴⁻⁸ have shown that 'fusogenic' agents such as fatty acids and their derivatives induce erythrocytes to fuse. Such agents might possibly promote fusion by enabling endogenous lipids to assume non-bilayer configurations. We have therefore investigated the influence of two such fusogens on the structure of the erythrocyte (ghost) membrane using ³¹P NMR techniques, which have been found to be sensitive to phospholipids in non-bilayer phases^{9,10}. We show that the incorporation of oleic acid and glycerol mono-oleate into the ghost membrane, at concentrations similar to those needed to induce cell fusion between erythrocytes *in vitro*, produce a well-defined transition of a variable portion of the membrane phospholipids from the bilayer phase to an hexagonal (H_{II}) phase. These results lead us to propose a model for membrane fusion induced by oleic acid, which we suggest may also apply to fusion events *in vivo*.

The phases available to hydrated liquid crystalline phospholipids, and the corresponding ³¹P NMR spectra obtained are illustrated in Fig. 1. Briefly, the phospholipids in (large) bilayer structures give rise to broad asymmetric ³¹P NMR spectra with a low field shoulder⁹⁻¹⁴. Alternatively, phospholipids in the hexagonal (H_{II}) phase (ref. 15) exhibit narrower

spectra with a high field shoulder¹⁰. Finally, phospholipids in other available phases exhibit much narrower symmetrical ³¹P NMR spectra¹⁰.

The 36.4 MHz ³¹P NMR spectra obtained from erythrocyte ghosts incubated in the presence of increasing amounts of oleic acid are shown in Fig. 2. A progressive conversion of the membrane phospholipids from the bilayer phase to the hexagonal (H_{II}) phase is observed. Similar effects were also observed for glycerol mono-oleate. Such spectra cannot arise from lipids in

Fig. 1 Phospholipid phases and corresponding (36.4 MHz) ³¹P NMR spectra observed. The 36.4 MHz ³¹P NMR spectra were obtained from (unsonicated) aqueous dispersions of egg yolk lecithin at 30 °C (bilayer phase), soya phosphatidylethanolamine at 30 °C (hexagonal H_{II} phase) and a mixture of soya phosphatidylethanolamine and 15 mol% egg yolk lecithin at 30 °C (cubic, rhombic or inverted micellar phase, for fuller details see ref. 10). All aqueous dispersions contained 25 mM Tris-HAc (pH 7.1) and 2 mM EDTA. All spectra were obtained in the presence of high power (18 W) broad band proton decoupling.

Fig. 2 36.4 MHz ³¹P NMR spectra obtained at 37 °C from a, 150 mg (dry weight) erythrocyte ghost incubated in medium A (for details of incubation conditions and composition of medium A, see below) in the absence of oleic acid; b, 150 mg (dry weight) erythrocyte ghost incubated in medium A containing 35 mg oleic acid; c, 150 mg (dry weight) erythrocyte ghost incubated in medium A containing 50 mg oleic acid. The arrow indicates the position of ³¹P NMR spectra arising from sonicated vesicles. Erythrocyte ghosts were prepared from human bank blood as detailed previously²⁴ and were subsequently lyophilised and stored under N₂ at -20 °C before use. Medium A contained NaCl (0.12 M), KCl (6 mM), MgSO₄·7H₂O (5 mM), CaCl₂·2H₂O (2 mM) and Tricine (20 mM), and the pH adjusted to 6.8. The oleic acid was added drop by drop to 40 ml of medium A and subsequently sonicated (5 min) to obtain a milky suspension which was added to the (dry) ghost material. The resulting mixture was incubated at 37 °C for 20 min while stirring continuously. The material was subsequently centrifuged (50,000g) for 10 min at 0 °C and 0.1 ml D₂O (25 mM Tris-HAc, pH 7.0) added to the pellet, which was then transferred to the NMR tube. Spectra were obtained from up to 40,000 transients in the presence of high power (20 W) proton decoupling, using a 45° resonance frequency pulse and a 0.18 s interpulse time. Fatty acid determinations (see text) indicated an oleic acid to phospholipid ratio (mol/mol) of 1.3 for sample (b) and 2.4 for sample (c).

micellar or inverted micellar phases, or from bilayer phase lipids in rapid exchange with such micellar phases, as either situation would give rise to a narrow spectral component (≈ 20 Hz linewidth) with a chemical shift characteristic of isotropic averaging. Freeze fracture electron micrographs obtained from the sample of Fig. 2c reveal (Fig. 3) that the protein is segregated away from regions of the H_{II} phase, which exhibit a characteristic striated pattern consistent with previous freeze fracture visualisations of the H_{II} phase in model systems¹⁶.

The formation of the H_{II} phase was observed to be strongly dependent on the presence of Ca^{2+} in the incubation medium. Incubations equivalent to that performed for the sample of Fig. 2c but where Ca^{2+} was omitted resulted in broad, rather featureless ^{31}P NMR spectra which could not be clearly identified with either the bilayer or H_{II} phases. Control experiments (see below) showed that similar concentrations of oleic acid were associated with the ghost membrane in both situations. ^{31}P NMR studies were also performed on liposomes composed of the total lipids extracted from the erythrocyte membrane (to which various amounts of fusogen had been added prior to hydration) in the presence and absence of Ca^{2+} . Addition of Ca^{2+} to these systems promoted the formation of the H_{II} phase (above a fusogen/phospholipid ratio of 1 mol/mol). This provides strong evidence that Ca^{2+} directly facilitates the formation of the H_{II} phase in the ghost membrane. This apparent ability of Ca^{2+} to induce bilayer to hexagonal (H_{II}) phase transitions may be related to the previously noted^{17,18} ability of Ca^{2+} to cause lateral phase separation of charged lipid species in mixed lipid systems.

If the H_{II} phase formed in the fusogen-treated erythrocyte ghost membranes is relevant to the mechanism by which fusogens facilitate fusion between erythrocytes *in vitro*, similar amounts of fusogen should be associated with ghosts and erythrocytes when significant hexagonal (H_{II}) phase or fusion, respectively, is observed. Thus fusion was induced between erythrocytes, employing oleic acid, in the manner detailed previously⁷. The cells were centrifuged on observation of initial fusion events (10–20% fusion, as observed in a phase contrast microscope), and a fatty acid analysis of the pellet allowed a determination of the oleic acid associated with the cells. Excess fatty acid floated on the supernatant after centrifugation. Approximately 1 mol of oleic acid per mol of erythrocyte phospholipid was required before significant fusion occurred. This may be compared to an oleic acid/phospholipid ratio of 1.3 (mol/mol) obtained for the sample of Fig. 2b where significant formation of the H_{II} phase is observed. Assuming that a similar proportion of the membrane associated fusogen is contained in the ghost and erythrocyte bilayers respectively, these results indicate that membrane concentrations of fusogen sufficient to initiate fusion in erythrocytes are also sufficient to promote formation of the H_{II} phase in the ghost membrane. This suggests that observation of the H_{II} phase in the ghost system corresponds to ghost fusion (although this has not yet been observed by other techniques) and also suggests that formation, or a tendency to formation, of the H_{II} phase in the erythrocyte membrane itself is vital to subsequent fusion events.

On the basis of this information we propose a model of cell fusion induced by oleic acid which is illustrated in Fig. 4. The fusion event is envisaged to proceed through (at least) four stages; these involve aggregation of protein to produce areas of (protein free) lipid bilayer¹⁹, which subsequently make contact (Fig. 4b). It is then suggested that the two outer monolayers combine to form an intermediate hexagonal H_{II} phase (Fig. 4c) which is subsequently restabilised to bilayer structure (Fig. 4d) to complete the fusion process. The presence of Ca^{2+} is probably important at each stage, indeed Ca^{2+} has already been implicated in the processes of protein aggregation and cell-cell contact²⁰. We emphasise, however, that the presence of Ca^{2+} would seem to be particularly important for the formation of the H_{II} phase of Fig. 4c. Further, the resta-

Fig. 3 Freeze-etch electron micrograph obtained from erythrocyte ghost sample giving rise to the spectra of Fig. 2c. The sample was quenched from 20 °C. Other conditions were as detailed previously²⁵. Magnification $\times 250,000$.

bilisation event may be envisaged to occur by way of an active (ATP-dependent) removal of Ca^{2+} from the cytoplasm of the partially fused cells of Fig. 4c, thus producing a strong chemical potential between the aqueous pores of the H_{II} phase and the cytoplasm. This would encourage the removal of Ca^{2+} and subsequent reversion of the H_{II} lipid to the bilayer phase.

There are strong indications that the mechanism of membrane fusion shown in Fig. 4 may also apply to naturally occurring membrane fusion *in vivo*. In particular, many species of naturally occurring lipids found in significant concentrations in biological membranes prefer the hexagonal (H_{II}) phase or other inverted phases (intermediate formation of inverted micelles would be equally acceptable to the fusion model of Fig. 4) over bilayer structure. Notable examples include unsaturated phosphatidylethanolamines^{9,10,21,22} and cardiolipin²³. Moreover, the formation of H_{II} phases for both these lipid species may be facilitated by the presence of Ca^{2+} (ref. 23 and P. R. Cullis, unpublished). Cholesterol also tends to favour the formation of hexagonal (H_{II}) phases in certain situations¹⁰. Thus 'natural fusogens' abound, and segregation of such non-bilayer lipids into particular regions of the membrane (in the presence of Ca^{2+}) would be expected to facilitate fusion events. Cell-cell contact in the form of Fig. 4c may also correspond to 'quasi-fusion' events²⁰ associated with tight junctions.

We thank Professor L. L. M. van Deenen for his support and for laboratory facilities and Dr A. J. Verkleij for performing

Distribution of sialic acids on the red blood cell membrane in β thalassaemia

SIALIC acids (SA) of the red blood cell (RBC) membrane are considered to play an important part in the physiology of the RBC¹. There are indications that the amount of membrane sialic acid is a major factor in distinguishing young from aged RBC. Thus, ageing of circulating RBC is associated with a reduction of 20–30% SA which may be an important determinant of RBC survival^{2,3} in the eventual recognition and sequestration of the latter cells by the reticuloendothelial system². During studies of thalassaemic RBC we observed, among other alterations, that the average level of SA was approximately 25% less than in normal RBC membranes obtained from healthy donors⁴. We, therefore, investigated the comparative ultrastructural distribution of SA on the surface of thalassaemic RBC membranes. We found that the SA residues on the surface of thalassaemic RBC are distributed in an uneven manner and are less abundant than those present on normal RBC surfaces.

We used three cytochemical methods in conjunction with transmission electron microscopy, in order to detect SA on membranes of intact RBC. One method is based on the production of a biotinyl derivative of SA which can be visualised by ferritin-avidin conjugates as described previously^{5,6}. In addition, two other techniques were used, cationised ferritin (CF) (ref. 7) and ruthenium red⁸, both of which interact with negatively charged sites on the membrane. The latter techniques were used because membrane-based sialyl residues are known to contribute most of the negative charge on the surface of the human RBC⁹.

The results obtained from all three techniques are illustrated in Fig. 1. The distribution of the above membrane probes from representative thalassaemic RBC samples was compared with that of normal RBC. In the former cases, only cells with characteristic thalassaemic morphology^{10,11} were evaluated. Both normal and thalassaemic RBC stained with ruthenium red, and a continuous layer of electron-dense material was observed. The deposit was much less dense, however, on the surface of thalassaemic RBC (Fig. 1a) than on normal cell membranes (Fig. 1b).

Unlike the ruthenium red stain, which results in an amorphous layer of reaction products, ferritin-based stains are characterised by a particulate marker of uniform size. The ferritin label can be quantitatively evaluated by enumeration and enables a finer resolution of the given surface site. Thus, quantification of cationised ferritin (CF) on micrographs of tangentially sectioned membrane (Figs 1c and d) revealed less attached CF particles per μ^2 on thalassaemic cells ($1,200 \pm 275 \sigma$) than on normal RBC ($2,030 \pm 150 \sigma$). In some instances the CF label on the former cell membranes was interrupted by unlabelled gaps (Fig. 1c, arrows), in contrast to the more even distribution of the label on normal RBC.

Additional details of the distribution of membrane SA were obtained by a more specific technique using ferritin-

avidin conjugates to visualise biotinylated sialyl residues. Examination of perpendicularly sectioned membranes obtained by this technique reveals the topographical resolution of sialyl residues from the lipid bilayer^{6,7}. With the above method, ferritin particles on the surface membrane of thalassaemic RBC are distributed in patches separated by unlabelled gaps (Fig. 1e). In addition, a distance of up to 300 Å could be discerned between some of the aggregated ferritin particles and the plane of the membrane surface. These observations may indicate either that some SA residues on thalassaemic RBC are associated with oligosaccharides of a more complex nature or that these sites have been displaced from the membrane surface. These phenomena were absent in normal RBC labelled in the same manner. In the normal RBC membrane, ferritin particles were almost uniformly distributed and protruded about 50–100 Å from the outer electron-dense layer of the cell membrane (Fig. 1f).

These ultrastructural observations support biochemical data which indicate that less SA are present on the surface membrane of thalassaemic RBC⁴. Similar observations on RBC membranes obtained from patients with β -thalassaemia intermedia are summarised in Table 1. Although the latter form of thalassaemia is morphologically indistinguishable from β -thalassaemia major, the clinical course is less severe, and the patients do not require

Fig. 1 Distribution of membrane probes on thin sections of thalassaemic (a, c, e) and normal (b, d, f) RBC. Thalassaemic RBC (a) stained with ruthenium red. Note the relatively thin layer of the reaction products when compared with normal RBC (b). Tangential section of thalassaemic RBC (c) treated with cationised ferritin (CF). The labelling pattern is interrupted by unlabelled areas (arrows). Quantification of the CF label on tangentially sectioned thalassaemic membranes showed reduction of about 40% compared with the uniformly CF-labelled normal RBC (d). Perpendicular section of thalassaemic RBC membrane (e) treated as follows: cells, washed in PBS, were reacted with 1 mM sodium periodate, washed twice, and treated with biotin hydrazide (2.5 mg ml⁻¹). Cells were then fixed for 30 min at room temperature with Karnovsky's fixative, labelled with ferritin-avidin conjugates (1 mg ml⁻¹ ferritin)^{6,7}, washed again, post-fixed with 1% osmium tetroxide and embedded in Epon 812. Perpendicular section of representative RBC membrane from healthy donors (f) treated in the same manner as in e. Note the presence of aggregates separated by unlabelled gaps in e, in addition to the distance (arrows) of some of the ferritin particles from the membrane surface. In contrast, a uniform labelling pattern is obtained on normal RBC membranes in f. Magnifications: a, b $\times 40,000$; c, d $\times 80,000$; e, f $\times 60,000$.

Table 1 Sialic acid content of thalassaemic and control RBC membranes

Membranes	($\mu\text{g mg}^{-1}$) Membrane protein
Control (9)	44.9 \pm 2.5
β -Thalassaemia major (17)	28.4 \pm 3.3
β -Thalassaemia intermedia (4)	27.3 \pm 4.1

The RBC membranes were prepared as described by Kahane and Rachmilewitz⁴. Sialic acids were determined by the thiobarbituric acid procedure¹³. The number of samples tested is indicated in parenthesis.

frequent blood transfusions¹⁰. Nevertheless, the distribution of SA on the RBC surface in these patients was similar to that seen on β -thalassaemia major RBC membranes (Fig. 1e).

The underlying mechanism for the observed reduction in surface SA in thalassaemic RBC is still unknown. Several factors could be responsible for this phenomenon. Membrane biogenesis may be defective in precursor cells, leading to the release of RBC with altered content and distribution of SA. Alternatively, reduced SA levels could be attributed to an enhanced rate of their removal from thalassaemic RBC membranes. Thus, the short life-span of thalassaemic RBC¹⁰ may be related to an increased rate of sequestration due to the loss in surface SA.

Recently, Riggs and Ingram¹² have also reported lower levels of SA in RBC membranes of patients with sickle cell anaemia. In view of the results recorded here, it is possible that a reduction in SA may occur in other types of anaemia. The potential interrelationship between the reduced sialic acid content in the membrane and RBC pathology warrants further investigation.

We thank Mr P. Benda for his support in this study and Fani Reichert for excellent technical assistance. E.A.R. is an established investigator of the Chief Scientist's Bureau, Ministry of Health, Israel.

Intraventricular kainic acid preferentially destroys hippocampal pyramidal cells

THE hippocampus is particularly vulnerable to a variety of conditions, such as anoxia, status epilepticus and senile dementia, in which central neurones are lost^{1,2}. Most commonly, the lesion involves only the Sommer sector (h_1) and the endfolium (h_3 – h_5), sparing area h_2 , the fascia dentata and most regions outside the hippocampal formation. The consequences for hippocampal connections are unknown. Studies on the rat hippocampus suggest that connections made by the affected neurones could be replaced by axons of other neurones which project to the same areas^{3,4}. These anomalous synapses might either compensate in part for the loss of cells or contribute to whatever functional deficits may derive from the lesion. Since a good deal is known about afferent and efferent hippocampal connections in the rat, this animal might serve as a model for studies of hippocampal damage. However, the selective pathology seen clinically cannot be reproduced by conventional lesioning techniques. Ideally, one would like to use a toxin relatively specific for the neurones in question. Kainic acid, a potent excitatory analogue of glutamic acid^{5–7}, has been used to destroy neurones in the arcuate nucleus⁸ and striatum,^{9–11} while sparing fibres which pass to or through these regions. Previous workers have also briefly noted lesions in the hippocampus,^{8,11} but these were not described. Accordingly, we injected kainic acid intraventricularly into the rat brain and studied its effect on hippocampal neurones. We now report the unusual sensitivity of CA3–CA4, and to a lesser extent CA1, pyramidal cells to this agent. Our results suggest that kainic acid lesions can provide a model of hippocampal damage in man.

Male Sprague–Dawley rats (60–150-d-old) were anaesthetised with sodium pentobarbital and positioned in a stereotaxic apparatus (David Kopf Instruments) with the nose bar set at +5. A hole was drilled on bregma at 1.5 mm lateral to the midline, and a 1- μ l unbevelled Hamilton syringe was inserted to a depth of 4.7 mm from the surface of the skull. Kainic acid dissolved in 1 μ l of Elliott's artificial cerebrospinal fluid¹² (pH 7.3–7.5) was infused over a 30-min period. After 1–55 d the rats were killed by transcardial perfusion with neutralised formalin in normal saline, and the brains were examined histologically.

A modified Fink–Heimer method¹³ was used to detect degenerating neurones 1 and 3 d after kainic acid treatment. Argyrophilic (degenerating) hippocampal neurones (Fig. 1b) were seen at these survival times after unilateral injection of as little as 0.1 μ g (about 0.5 nmol). At this dose kainic acid killed only the pyramidal cells in area CA3a at the rostral pole of the hippocampus. Increasing doses destroyed pyramidal cells at increasingly caudal levels and in additional subfields. Cell destruction proceeded from the entrance of the fimbria (area CA3a) toward the dentate hilus (areas CA3c and CA4). At a dose of 0.8 μ g argyrophilic pyramidal cells were seen throughout areas CA3 and CA4 in all sections cut through the rostral half to two-thirds of the hippocampal formation (Fig. 1a). Intermediate patterns were obtained when 0.3 or 0.5 μ g was administered. Doses higher than 0.8 μ g were usually required to kill the pyramidal cells of area CA1, and the pyramids in area CA2 were seldom destroyed by any non-fatal dose (LD₅₀ of about 1.1 μ g). Dentate granule cells were destroyed only when 3 μ g of the drug was injected directly into the hippocampus. This hierarchy of sensitivity to kainic acid resembled that of hippocampal neurones to injurious conditions in man, and it could not be explained by the proximity of affected neurones to the lateral ventricle.

At 1 d after injection the degenerating elements were predominantly cell bodies and dendrites. By 3 d, however, we could identify a substantial number of degenerating axons and boutons. Kainic acid did not directly damage the septo-

hippocampal fibres (Fig. 2b) nor the hippocampal mossy fibres, whose cell bodies of origin remained intact. Thus, as in other regions,^{8,14,15} kainic acid selectively attacked cell bodies and dendrites, whereas axons of the same cells were only secondarily affected and afferent fibres were apparently unaffected.

In adjacent sections stained with cresyl violet degenerating cell bodies appeared severely shrunken, and their nuclei stained more darkly than normal (Fig. 1d). These neurones appeared to have been partially removed by 3 d after injection (Fig. 1c), although degenerating neurones could still be seen in some cases for at least 2 weeks. Over a period of several weeks areas of massive neuronal degeneration became gliotic and then atrophied (Fig. 2). Kainic acid exerted its toxic action directly on the hippocampus and not indirectly through an action elsewhere since the same histological results were obtained after intrahippocampal injection. That argyrophilic neurones actually degenerated and were not merely damaged reversibly was shown by the reduction or absence of neurones 1–2 months after injection in areas where argyrophilic cells were present at earlier times (Fig. 2a).

Argyrophilic neurones were not detected in regions other than hippocampus, when 0.1–0.3, and usually 0.5, μ g were administered, except for perhaps a few cells in the lateral septum immediately adjacent to the site of injection. Thus at these dosage levels kainic acid produced a fairly pure hippocampal lesion. With increasing dose, argyrophilic neurones were observed in additional regions, including some of the thalamic nuclei, amygdala and deep layers of the cerebral neocortex (but not striatum or hypothalamus). In man, cell loss in these regions often accompanies loss of hippocampal pyramidal cells.^{1,2} No degenerating cells were identified in areas known to project to the hippocampal formation, except in nucleus reuniens of the thalamus¹⁶ and in layer III of the entorhinal cortex.

Animals given intraventricular kainic acid showed symptoms of a partially suppressed convulsion lasting 3–4.5 h. At all doses

Fig. 1 Frontal sections through the dorsal rat hippocampal formation 3 d after ipsilateral intraventricular injection of 0.8 μ g of kainic acid. *a*, Diagram of hippocampal formation showing the location of degenerating pyramidal cells (x). The hippocampal formation is divided into fields according to Lorente de N \acute{o} . Area CA1 corresponds roughly to h_1 in man, CA2 to h_2 , CA3 to h_3 and h_4 and CA4 to h_5 . Dashed lines denote the hippocampal fissure and the border of areas CA1 and CA2. FD, fascia dentata; F, fimbria; triangles, normal-appearing pyramidal cells; circles, dentate granule cells. A few scattered normal-appearing neurones were also found among the degenerating cells. *b*, High power view of part of area CA3c showing degenerating pyramidal cells. A few normal-appearing neurones (arrow) are also present. Fink–Heimer stain. Scale bar, 0.05 mm. *c*, Adjacent section stained with cresyl violet showing neuronal loss in areas CA3 and CA4. Note the glial proliferation in these areas. Scale bar, 0.5 mm. *d*, High power view of part of area CA3c showing darkly-stained shrunken pyramidal cells. Small dark bodies are probably glial cells. Some normal-appearing neurones (arrow) remain. Cresyl violet stain. Scale bar, 0.05 mm.

Fig. 2 Dorsal hippocampal formation 34 d after intraventricular injection of 0.8 µg of kainic acid. Injected side on the right, contralateral side on the left. Ipsilateral areas CA3 and CA4 have atrophied noticeably by this time. *a*, Cresyl violet stain to show permanent loss of pyramidal cells in areas CA3 and CA4. Note persistent gliosis in affected areas. Scale bar, 0.5 mm. *b*, Acetylcholinesterase stain to show preservation of septohippocampal fibres^{25,26}. The density and distribution of these fibres is unaltered by kainic acid. Timm's sulfide silver staining of mossy fibres²⁷ showed those fibres were also unaffected. Scale bar, 0.5 mm.

these included vibrissa tremor and distended eye ipsilateral to the injection and at doses of 0.8 µg and above there was in addition upper body tremor, rigidity of the limbs and foaming at the mouth. Several convulsants which interfere with GABA-mediated transmission and induce prolonged hippocampal seizures produce neuronal damage in baboons¹⁷⁻¹⁹ and cats²⁰ similar to that which kainic acid causes in rats. These agents probably induce a seizure through disinhibition, whereas kainic acid depolarises neurons directly. The similar pathology in these cases suggests that the cell loss in the present study resulted from a prolonged hippocampal seizure, similar to an episode of status epilepticus.

With regard to its mechanism of action, previous workers have assumed that kainic acid serves simply as a potent glutamate agonist, interacting with a glutamate receptor to effect a prolonged depolarisation. This chronic excitation would then lead to an irreversible ionic imbalance resulting in cell death. Indeed the destructive effects of the two amino acids on striatal and arcuate neurones appear very similar,^{8,10} although they are effective at doses about two orders of magnitude apart. In hippocampus, however, we have found glutamic acid to be virtually ineffective in destroying the pyramidal cells, even when it was injected directly into this region at a dose more than three orders of magnitude greater than the minimally effective dose of kainic acid. Furthermore, the dentate granule cells were quite resistant to the toxic effects of this agent, even though glutamate probably serves as a major excitatory transmitter in the fascia dentata²¹⁻²³ and the granule cells are readily depolarised by iontophoretically applied glutamate (unpublished observation). These results raise the possibility that either the glutamate receptors in the hippocampal formation differ from those in the striatum and arcuate nucleus or the destructive effects which kainic acid elicits in the hippocampus are not mediated through an interaction with a glutamate receptor.

Since kainic acid preferentially affects those neurones which are most susceptible to damage by a variety of adverse conditions, these lesions may provide a useful model of hippocampal injury in man. Kainic acid should prove advantageous in investigations of (a) the vulnerability of the hippocampus, particularly in status epilepticus, (b) the plasticity of hippocampal connections after brain damage and (c) the presently controversial behavioural role of the hippocampus.

In vitro release of Leu- and Met-enkephalin from the corpus striatum

We have suggested previously that Met-enkephalin and Leu-enkephalin¹ may act as neurotransmitters in the central and peripheral nervous systems^{2,3}. Recent studies on the distribution of the enkephalins support this view⁴⁻⁶. An important step in establishing a possible neurotransmitter role of the enkephalins is the demonstration of their release from neuronal sites by potassium ions or veratridine. Indirect evidence for the release of enkephalin or endorphin has been provided by several workers⁷⁻¹⁰. We now present direct evidence for such release from isolated brain slices and synaptosomal preparations.

The experiments were carried out on preparations of the rabbit and guinea pig striatum, which contain very high endogenous levels of Met- and Leu-enkephalin. The enkephalins were isolated by adsorption on Amberlite CG-400 and elution with formic acid¹¹, followed by adsorption on, and elution with methanol from, Amberlite XAD-2 (ref. 3). All the samples were assayed on the mouse vas deferens with Met- and Leu-enkephalin as standards. Antagonism by naloxone (900 nM) was routinely used in each assay to check for specific opioid peptide activity.

A small basal release of enkephalin (0.4% of tissue content in 30 min) was detected in the superfusate from a layer of crude synaptosomes prepared from rabbit striatum (Table 1). When the potassium ion concentration of the superfusion fluid was increased from 5.94 to 50 mM, the amount of enkephalin recovered in a 15-min collection increased to 1.9% of the tissue content. A second perfusion, 30 min after the first, with Krebs solution containing 50 mM K⁺, produced a much smaller release of enkephalin. In a separate set of experiments, the concentration of calcium chloride was increased to 5.08 mM and the potassium-evoked release of enkephalin was more than double that in Krebs solution containing 2.54 mM calcium chloride. Omission of calcium chloride from the medium mar-

Table 1 Enkephalin release from rabbit striatal synaptosomes

Calcium chloride and potassium ion concentrations in Krebs solution (mM)		No. of experiments	Fractional release (%) during a collection period	
CaCl ₂	K ⁺		1st collection	2nd collection
2.54	5.94	11	0.4±0.2	0.2±0.15
5.08	5.94	4	0.5±0.2	—
2.54	50	4	1.9±0.3	0.5±0.15
5.08	50	4	4.4±0.2	0.9±0.2
0	50	3	0.8±0.1	—
0+EDTA (0.5 mM)	50	3	not detectable	—

A crude synaptosomal fraction (P₂) of rabbit striatum was prepared by homogenising (Teflon pestle and glass tube) 0.8–1.0 g of tissue in 0.32 M sucrose (1 g tissue per 10 ml sucrose). The nuclear fraction (10,000g min) was discarded and the P₂ fraction obtained by centrifuging the supernatant at 17,000g for 20 min. The P₂ pellet was resuspended in Krebs solution and layered on a 1-cm diameter filter superfused with Krebs solution at 36 °C, gassed with 95% O₂ and 5% CO₂. The preparation was superfused for 20 min before collecting the superfusate. Basal release at 2.54 mM CaCl₂ and 5.94 K⁺ was determined in 30-min periods and potassium-evoked release in 15-min collection periods. Fractional release refers to the total enkephalin activity (measured as Met-enkephalin) released during a collection period into the superfusate and is expressed as % of the tissue content. In some experiments a second collection of superfusate was made 30 min after the first collection. All determinations were made in separate experiments, apart from the second collections. The limit of sensitivity of the assay was 0.5 ng. The values are the means±s.e.m.

kedly reduced the evoked release of enkephalin; the addition of EDTA to the calcium-free medium reduced the release to undetectable levels.

It has been suggested that Met-enkephalin is merely a proteolytic breakdown product of β -endorphin¹². Experiments were carried out to test the possibility that the source of the released enkephalin might be the larger endorphins released into the medium and subsequently degraded, rather than the direct release of enkephalin. In three perfused synaptosomal preparations, β -endorphin was added to the superfusion medium so that 1 nmol of the peptide passed through the layer of synaptosomes in 15 min. There was no detectable increase in enkephalin above basal levels in each of these experiments. The breakdown of only 0.1% of the β -endorphin to Met-enkephalin would have been detected (sensitivity of assay, 0.5 ng Met-enkephalin), and so we conclude that cleavage of β -endorphin does not occur to any significant extent under our experimental conditions.

The effect of potassium as a depolarising agent is not specific for neurones. Veratridine may be considered a more specific stimulus¹³, and therefore we tested the effect of this agent on enkephalin release from superfused slices of the guinea pig striatum. Preliminary experiments established that the release by veratridine was small and variable, which was considered to be due to enzymatic breakdown of enkephalin. A series of di- and tripeptides were screened for their ability to reduce breakdown. It was found that a combination of leucyl-leucine, leucyl-glycine and tyrosyl-tyrosine (each 1 mM) prevented the breakdown of both Met- and Leu-enkephalin when incubated with either brain homogenates or striatal slices. The inhibition by the dipeptides decreased with time, suggesting

that the mechanism of action might be substrate competition. Control experiments showed that the recovery of added Met-enkephalin from superfused striatal slices increased from 47±5% (*n* = 5) in the absence of the dipeptides to 97±11% (*n* = 5) in their presence.

In the presence of the dipeptides, no basal release of enkephalin (<0.5 ng) could be detected in 10-min collections of striatal superfusate. The addition of veratridine (50 μ M) to the superfusing fluid for 2–10 min caused a release of enkephalin. During a prolonged exposure to veratridine (10 min), the output of enkephalin increased over the first 6 min and then declined (Fig. 1a). When slices were exposed to veratridine for 3 min, at intervals of 30 min, the output of enkephalin declined with successive exposures (Fig. 1b). A similar phenomenon was seen with potassium-evoked enkephalin release from synaptosomes. This decrease in output with successive exposures to veratridine may be due to incomplete recovery of the tissue from the preceding intense stimulation, depletion of the releasable store of enkephalin, or a decrease in the viability of the slices during the course of the experiment. Tetrodotoxin (1.7 μ M) abolished the veratridine-induced output of enkephalin (Fig. 1b).

In another series of experiments, the material released by veratridine was analysed by thin layer chromatography to separate Met- and Leu-enkephalin (Table 2). Both peptides were found to be present in the superfusate and the tissues. The ratio of Met-enkephalin to Leu-enkephalin released from the guinea pig striatum was very similar to the ratio of these peptides present in the tissue.

Our results from striatal synaptosomes and slices indicate that the enkephalins, in common with other putative neurotransmitters, are released from brain tissue by an increase in

Table 2 Comparison of stimulated output and tissue content of Met-enkephalin and Leu-enkephalin

	No. of experiments	Met-enkephalin (ng)*	Leu-enkephalin (ng)*	ratio Met/Leu†
stimulated output	6	5.5±0.9	1.7±0.16	3.4±0.5
tissue content	4	79±22	20±5	3.8±0.2

Guinea pig striatal slices (600- μ m thick, sagittal section) from two striata weighing approximately 300 mg were used in each experiment. The slices were superfused (1.1 ml min⁻¹) for 45 min with Krebs solution at 36 °C and gassed with 95% O₂ and 5% CO₂. The slices were exposed to veratridine (50 μ M) for 10 min and the superfusate collected for 20 min from the start of exposure to veratridine. The dipeptides, Leu-Leu, Tyr-Tyr and Leu-Gly (each 1 mM) were present in the superfusing fluid for 5 min before exposure to veratridine and throughout the collection period. For the determination of endogenous enkephalins, the tissues were homogenised in 0.1 M HCl. All samples (superfusate and tissues) were chromatographed on Amberlite CG-400 and XAD-2 columns, then spotted on 0.25-mm silica gel plates and developed with ethyl acetate:pyridine:water:acetic acid:ethane-1,2-dithiol (100:44:25:11:0.2). The marker lanes were stained with cadmium-ninhydrin reagent, and the areas corresponding to Met-enkephalin (*R_f* \approx 0.4) and Leu-enkephalin (*R_f* \approx 0.55) were removed, eluted and assayed. The values are the means±s.e.m.

*Uncorrected for recovery from all chromatographic procedures; this was estimated to be 30–35%.

†Ratios calculated from individual experiments.

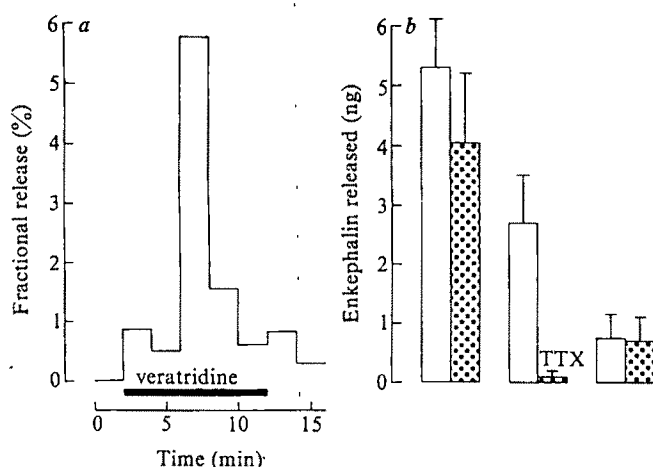

Fig. 1 Release of enkephalin from guinea pig striatal slices. The slices were superfused (1.1 ml per min) for 45 min with Krebs solution at 36 °C and gassed with 95% O₂ and 5% CO₂. *a*, 600 μ m thick sagittal sections from two striata weighing approximately 300 mg were exposed to veratridine (50 μ M) for 10 min. The superfusate was collected at 2-min intervals. Fractional release refers to the total enkephalin activity (assayed as Met-enkephalin) released into the superfusate expressed as a % of the tissue content. *b*, 450 μ m thick sagittal sections from one striatum weighing approximately 150 mg were exposed to veratridine (50 μ M) for 3 min every 30 min. The superfusate was collected for 12 min from the start of veratridine exposure. The open columns represent the output of enkephalin on three successive exposures to veratridine. The stippled columns represent the output of enkephalin from tissues in which the second exposure to veratridine was made in the presence of 1.6 μ M tetrodotoxin (TTX). All outputs were assayed as Met-enkephalin. Each column represents the means from three experiments, the vertical bar indicating s.e.m. In both *a* and *b*, Leu-Leu, Tyr-Tyr and Leu-Gly (each 1 mM) were present in the superfusing fluid for 5 min before exposure to veratridine and throughout the collection periods. All samples (superfusate and tissues) were chromatographed on only Amberlite CG-400 and XAD-2 columns with a recovery of 90–100%. No attempt was made to separate Leu-enkephalin from Met-enkephalin.

potassium ions or veratridine. The potassium-induced release is calcium-dependent and the effect of veratridine is abolished by tetrodotoxin. We suggest that the source of this evoked release is the neuronal stores of enkephalins and that the present results provide additional direct evidence that Met- and Leu-enkephalin may act as central neurotransmitter agents.

Release of enkephalin from rat globus pallidus *in vitro*

SINCE the discovery of the endogenous opioid peptides Leu- and Met-enkephalin in mammalian brain, there has been considerable interest in their possible physiological functions^{1–3}. Recent immunohistochemical studies have shown that the enkephalins are localised in neurones in various regions of the central nervous system, with high concentrations in nerve terminals^{4,5}. These morphological studies and the results of detailed regional analyses of rat brain by radioimmunoassay have indicated that enkephalin-containing nerve terminals are particularly concentrated in the rat globus pallidus, which by radioimmunoassay has been found to contain a concentration of enkephalin six to eight times higher than that observed in any other brain region^{6,7}. Here, we describe a calcium-dependent evoked release of enkephalin-like immunoreactivity from slices of rat globus pallidus *in vitro*. This finding supports the view that enkephalins may be released as neurotransmitter substances from nerve terminals in the brain.

Globus pallidus tissue was dissected from each side of thick frontal sections of chilled rat brain, using the anatomical landmarks of the atlas of König and Klippel⁸. The pooled samples of tissue from left and right sides weighed approximately 30 mg and were contaminated with small amounts of adjacent striatal and thalamic tissue. The tissue from each brain was cross-cut at 200- μ m intervals with a McIlwain tissue chopper, and the resulting slices were suspended in Krebs-bicarbonate medium in a small plastic superfusion chamber at 37 °C, as described previously^{9,10}. The slices were superfused with a modified Krebs-bicarbonate medium at 37 °C, containing bovine serum albumin and bacitracin to protect against loss of released enkephalin by absorption or metabolism. After an initial wash period of 13 min, superfusate samples were collected at 3-min intervals and aliquots were analysed for enkephalin using a sensitive radioimmunoassay procedure^{11,12}. This assay involved the use of an anti-Leu-enkephalin rabbit serum for which Leu-enkephalin had an affinity some 30 times higher than that of Met-enkephalin. It was thus not possible to distinguish between Leu- and Met-enkephalin, and the results were calculated in terms of units of enkephalin (1 unit = 1 ng Leu-enkephalin equivalent). Since rat globus pallidus is reported to contain a sixfold preponderance of Met-enkephalin over Leu-enkephalin⁷, the observed immunoreactivity was probably due to a mixture of the two peptides.

A rapid release of enkephalin-like immunoreactivity was observed during the initial 13-min wash-out period; after this, however, the spontaneous release of enkephalin decreased to 0.1–0.2% of the total tissue stores per minute. In several instances, the concentration of enkephalin present in such spontaneous release samples was less than 10 pg ml⁻¹, which represented the lower limit of accurate measurement for the radioimmunoassay procedure. During exposure to a high potassium medium (K⁺ 50 mM) for a 6-min period, there was a large increase in the rate of release of enkephalin-like immunoreactivity (Fig. 1a). During the period of potassium ion stimulation the rate of enkephalin release was 10–20 times higher than in the preceding spontaneous release samples, and a total of 9.6 \pm 1.8% of the total tissue enkephalin content was released during the 6-min stimulation period (mean \pm s.e.m., *n* = 10 experiments). On return to normal medium the efflux of enkephalin decreased rapidly to resting values similar to those observed before the stimulus. The release of enkephalin was very rapid during the initial 3 min of the period of potassium ion exposure, and was significantly slower during the second 3 min of the potassium ion pulse (Fig. 1). Further evidence for an exhaustion of the tissue stores of releasable enkephalin was obtained from experiments in which the tissue slices were exposed to a second potassium ion pulse 9 min after the first exposure (Fig. 2). The second exposure to potas-

sium ion released less than half as much enkephalin as the first, although the tissue content of enkephalin at the beginning of the second stimulation period was only some 10% lower than at the beginning of the first period of stimulation.

In the absence of calcium in the superfusion medium, the spontaneous release of enkephalin occurred at a low rate, similar to that observed in control experiments, and high potas-

Fig. 1 Release of enkephalin immunoreactivity from slices of rat globus pallidus superfused with normal (a) or calcium-free medium (b). The slices of pallidal tissue (about 30 mg wet weight) were superfused at a rate of approximately 300 μ l min⁻¹, and after an initial wash period of 13 min, samples of the superfusate were collected at 3-min intervals for subsequent radioimmunoassay. The superfusion medium was a modified Krebs-bicarbonate solution with the following composition: NaCl 127 mM; KCl 3.73 mM; CaCl₂ 1.8 mM; KH₂PO₄ 1.18 mM; MgSO₄ 1.18 mM; NaHCO₃ 20 mM; D-glucose 2 g l⁻¹. The medium was gassed with an oxygen/carbon dioxide (95%:5%) mixture, and contained bovine serum albumin (Sigma, crystalline) (0.1%, w/v) and the peptidase inhibitor bacitracin (Sigma) (30 μ g ml⁻¹). Twenty microlitres of a saturated solution of Na₂EDTA was added to each of the tubes used to collect the superfusate samples as a further precaution to protect released enkephalin from enzymatic degradation. During the period indicated by the horizontal black bars the slices were exposed to a medium in which KCl was substituted for NaCl to give a final K⁺ concentration of 50 mM. One hundred microlitre aliquots of the superfusates were analysed for enkephalin using a radioimmunoassay procedure¹¹. Results are expressed as percentage total tissue enkephalin released per minute, based on measurements of the total tissue enkephalin content at the end of the superfusion (Table 1). This was estimated after extraction of the tissue with boiling 1 M acetic acid, homogenisation and neutralisation of the centrifuged extracts, as described previously¹¹. Control values (a) represent means \pm s.e.m. for 10 experiments; results obtained with calcium-free medium (b) are means \pm s.e.m. for four experiments.

Fig. 2 Release of enkephalin from rat globus pallidus slices in response to two periods of exposure to high potassium medium. Mean values for two experiments; conditions as in Fig. 1a.

sium ion exposure was completely without effect in stimulating enkephalin release (Fig. 1b).

Measurements of the total enkephalin-like immunoreactivity in extracts of freshly dissected globus pallidus samples (Table 1) confirmed that this area of rat brain contains a very high concentration of enkephalin^{6,7}, amounting to 377 ± 15.4 units per g wet weight (mean \pm s.e.m., $n = 4$), a value some three to four times higher than that observed in rat striatum or hypothalamus in a previous regional survey using the same radioimmunoassay procedure¹². After a 40-min period of superfusion *in vitro*, the total enkephalin immunoreactivity of the tissue slices was markedly reduced when compared with the values obtained from fresh samples of globus pallidus tissue, indicating that some 60% of the total tissue enkephalin content was lost during the course of the experiments (Table 1). This is in contrast to the results obtained in analogous experiments with the other neuropeptides, substance P^{9,10} or somatostatin and neurotensin (L.L.I., S.D.I., F.E.B., M. Brown and W. Vale, unpublished), in which only a small proportion of the tissue stores of peptides were lost during a similar period of superfusion. The loss of tissue enkephalin during superfusion could not all be accounted for by the amounts of free peptide measured in the superfusate samples. During the 40-min superfusion period, approximately 25% of the total tissue enkephalin content was recovered as immunoreactive material in the superfusate samples; the remaining substantial loss of tissue enkephalin must presumably be attributed to enzymatic degradation, which was only partially inhibited by the addition of bacitracin¹³. The importance of adding this peptidase inhibitor was illustrated by the results of experiments in which bacitracin was

Table 1 Tissue content of enkephalin immunoreactivity in rat globus pallidus

Conditions	No. of experiments	Tissue enkephalin (units per globus pallidus sample)
Freshly dissected	4	11.32 ± 0.46
At end of 40-min control superfusion	10	4.62 ± 0.38
At end of 40-min superfusion in calcium-free medium	4	4.06 ± 0.52
At end of 40-min superfusion with control medium without bacitracin	4	4.17 ± 0.53

omitted. In these conditions, the spontaneous release of enkephalin was so low that it could not be measured accurately by the radioimmunoassay procedure in a majority of the resting efflux samples. Furthermore, although exposure to high potassium ion evoked a measurable release of enkephalin, the amounts collected during the 6-min period of exposure to high potassium ion represented only $5.8 \pm 1.5\%$ of the total tissue stores (mean \pm s.e.m., $n = 4$), significantly lower than the values observed in response to high potassium ion in media containing bacitracin. The tissue content of enkephalin at the end of these experiments, however, was not significantly different, whether or not bacitracin had been added to the medium (Table 1), suggesting that protection from enzymatic degradation is not important for stabilising enkephalin in its intracellular storage sites, but is critical in inhibiting degradation after the peptide has been released.

Because of this degradation, the observed percentage of enkephalin released should be viewed with some reservation. Since our antisera read both enkephalins, more detailed analysis of the release and stability of each enkephalin in these experimental conditions will be needed in order to arrive at more accurate estimates of the percentage of the total enkephalin content which can be released by potassium *in vitro*. Preliminary experiments indicate that the rate of catabolism of Met-enkephalin within the perfusion chambers is faster than that of Leu-enkephalin⁵. Nevertheless, the overall results of the present experiments have been validated in a variety of experimental conditions, with controls for release and peptidase inhibition.

In summary, the present results show that enkephalin can be released from rat brain *in vitro* in response to depolarisation caused by elevation of the external potassium ion concentration, and that this evoked release is completely dependent on the presence of calcium ions in the external medium. Such behaviour is characteristic of a number of other substances thought to be released as neurotransmitters in the central nervous system¹⁴⁻¹⁶, and strongly supports a neurotransmitter role for enkephalin in mammalian brain. A similar calcium-dependent potassium-evoked release of enkephalin has been described from rat brain synaptosome preparations¹⁷ and from rabbit guinea pig striatal tissue¹⁸.

Inhibition of hepatitis B DNA polymerase by intercalating agents

INFECTION with hepatitis B virus (HBV) is widespread and increasing in incidence in many countries. Unfortunately, there is as yet no effective chemotherapy. The hepatitis B virion is unique in that it contains both circular DNA and a DNA polymerase enzyme (for review see ref. 1). After the description of the enzyme² in concentrated preparations of hepatitis B antigen (HBsAg) containing Dane particles it was shown that enzyme activity was inhibited by intercalating agents such as ethidium bromide³. We have extended these early studies to include intercalating agents that can be safely administered to patients. We show here that several intercalating agents in clinical use inhibit the hepatitis B (HB) DNA polymerase reaction *in vitro* and we discuss the implications of these findings for the therapy of hepatitis B infection.

The following compounds were included in the study: ethidium bromide (molecular weight 394.3), chloroquine diphosphate (MW 515.9), primaquine diphosphate (MW 455.4), quinacrine hydrochloride (MW 472.9), methylene blue (MW 319.9), chlorpromazine (MW 355.3), quinine hydrochloride (MW 360.9) (all from Sigma) and hydroxychloroquine (MW 530, Sterling-Winthrop). Ethidium bromide and chloroquine have been shown to intercalate by changes induced in the superhelical density of the replicative form of Φ X174 DNA (ref. 4). Quinacrine, chlorpromazine, methylene blue and quinine change the superhelical density of PM-2 DNA in the manner of intercalators when examined by viscometric titration⁵. Primaquine has been shown to change the superhelical density of PM-2 DNA in the manner of intercalators at low ionic strength⁶.

Pellets of HBsAg containing Dane particles were prepared from patients' sera and shown to contain hepatitis B surface antigen (HBsAg) and hepatitis B core antigen (HBcAg) by methods described previously⁶. Assays for HB DNA polymerase were carried out in reaction mixture containing 0.15 M KCl and 0.01 M MgCl₂ (ref. 7), and in the differential assay mix⁸ containing 0.4 M KCl and 0.04 M MgCl₂ as previously described^{2,6,7}. The DNA product of the reaction was shown to be associated with HBcAg (ref. 6). Concentrated stock solutions of the drugs were prepared in distilled water and aliquots were added to the reaction mixtures to give the desired concentrations. The concentration of intercalating agent resulting in 50% inhibition (IC₅₀) of the HB DNA polymerase reaction was calculated from the results by a modification of the method of Reed and Muench⁹ where applicable.

Ethidium bromide, the archetype intercalating agent, was the most effective inhibitor of hepatitis B DNA polymerase amongst the drugs examined. The DNA polymerase reaction was inhibited by 90% at a concentration of $10 \mu\text{g ml}^{-1}$ (2.5×10^{-6} M) of ethidium bromide in reaction mixture containing 0.15 M KCl and 0.01 M MgCl₂ (Fig. 1a); the IC₅₀ was $3.2 \mu\text{g ml}^{-1}$ (8.1×10^{-6} M). Higher concentrations of magnesium ion interfered with inhibitory effect of ethidium bromide. Thus in 0.04 M MgCl₂ only 77% of the DNA polymerase reaction was inhibited at a concentration of $25 \mu\text{g ml}^{-1}$ of ethidium bromide and the IC₅₀ was $10 \mu\text{g ml}^{-1}$ (Fig. 1a). Inclusion of the non-ionic detergent Nonidet P-40 (NP-40) in the reaction mixture did not affect the inhibitory action of ethidium bromide on HB DNA polymerase.

The other intercalators studied, although not as toxic as ethidium bromide, are much weaker intercalators and were weaker inhibitors of HB DNA polymerase. However, several of the drugs inhibited HB DNA polymerase substantially at concentrations achievable in human liver⁹. Chloroquine, the mainstay of malarial prophylaxis, inhibited the DNA polymerase reaction by 45 and 53% at concentrations of 250 and $500 \mu\text{g ml}^{-1}$ respectively (Fig. 1b); the IC₅₀ was $480 \mu\text{g ml}^{-1}$ (9.30×10^{-4} M; Table 1). Quinacrine was a more effective inhibitor of HB DNA polymerase than chloroquine

(Fig. 1b); the IC_{50} for quinacrine was $334 \mu\text{g ml}^{-1}$ ($7.1 \times 10^{-4}\text{M}$; Table 1). Inclusion of NP-40 in the reaction mixture at a concentration of 0.3% interfered with the inhibition of the DNA polymerase reaction by chloroquine (Fig. 1b); NP-40 also interfered with the inhibition of the enzyme by quinacrine. Magnesium ion reduced the inhibitory activity of chloroquine (Fig. 1b); thus at a concentration of chloroquine of $500 \mu\text{g ml}^{-1}$ only 16% of the reaction was inhibited in the presence of 0.03 M MgCl_2 (Fig. 1b). Primaquine, another antimalarial

Fig. 1 Inhibition of hepatitis B DNA polymerase by intercalating agents. Pellets containing particulate HBAG, including Dane particles, were prepared by diluting serum 1:2 with phosphate-buffered saline (PBS), and centrifuging at $39,000g$ at 4°C , as previously described^{2,6}. The resulting pellet was washed in an equal volume of PBS or centrifuged through 5–20% sucrose gradients in PBS⁶. The final pellets were taken up in PBS in 1:20 of the original volume of serum. The standard DNA polymerase reaction mixture^{6,7} contained 0.05 M Tris-HCl, 20 mM dithiothreitol (DTT), 1 mM each of dATP, dCTP, and dGTP, and $2.5 \mu\text{Ci}$ of ^3H -dTTP at pH 7.5 in a final total volume of 0.1 ml. KCl, MgCl_2 , and NP-40, were included in the reaction mixture at various concentrations. The complete reaction mixture, including DNA polymerase-containing pellet suspension, was incubated at 38°C for 180 min. Enzyme activity was measured by the incorporation of ^3H -dTTP into acid-insoluble product^{6,7}. The ordinate represents enzyme activity expressed as % of control reactions not containing intercalators and the abscissa represents the concentration of intercalators in $\mu\text{g ml}^{-1}$. The same quantity of polymerase-containing pellet suspension was included in each reaction mixture. *a*, Ethidium bromide: ●—●, reaction mixture contained 0.4 M KCl, 0.04 M MgCl_2 and 0.3% NP-40; ●--●, same reaction mixture without NP-40; ▲—▲, reaction mixture contained 0.15 M KCl and 0.01 M MgCl_2 with 0.3% NP-40; ▲--▲, same reaction mixture without NP-40. Control reaction mixtures without intercalators in 0.04 M MgCl_2 with 0.3% NP-40 incorporated 2,200 c.p.m. of ^3H -dTTP per 0.1 ml reaction mixture into DNA; without NP-40 incorporation was 1,250 c.p.m. Control reactions without intercalators in 0.01 M MgCl_2 with NP-40 incorporated 1,100 c.p.m. of ^3H -dTTP and 875 c.p.m. without NP-40. Incorporation of 100 c.p.m. represents 4×10^{-3} pmol of ^3H -dTTP. *b*, ▲—▲, Chloroquine in reaction mixture containing 0.15 M KCl, 0.01 M MgCl_2 and 0.3% NP-40; ▲--▲, same reaction mixture with chloroquine but without NP-40. □, Chloroquine in reaction mixture containing 0.15 M KCl, 0.03 M MgCl_2 without NP-40. ×, Quinacrine in reaction mixture containing 0.15 M KCl, 0.01 M MgCl_2 without NP-40. Incorporation of ^3H -dTTP in control reactions without intercalators is given in (a) except that control reactions in 0.15 M KCl, 0.03 M MgCl_2 incorporated, 1,048 c.p.m.

agent, was a weak inhibitor of HB DNA polymerase; the IC_{50} of primaquine was $900 \mu\text{g ml}^{-1}$ ($2 \times 10^{-3}\text{M}$; Table 1). On the other hand, chlorpromazine was a very active inhibitor of the DNA polymerase reaction with an IC_{50} of $250 \mu\text{g ml}^{-1}$ ($7 \times 10^{-4}\text{M}$). Hydroxychloroquine and quinine hardly inhibited the enzyme reaction. However, methylene blue was a potent inhibitor of HB DNA polymerase; 94% of the reaction was inhibited at a concentration of $250 \mu\text{g ml}^{-1}$ of methylene blue ($7.8 \times 10^{-4}\text{M}$).

The inhibitory activity of combinations of intercalating agents against HB DNA polymerase was examined in order to determine whether additive or even synergistic effects would be observed. The combination of chloroquine and primaquine yielded moderately additive inhibitory effects on HB DNA polymerase (Table 2). Thus the combination of chloroquine at $500 \mu\text{g ml}^{-1}$ with primaquine at $250 \mu\text{g ml}^{-1}$ inhibited the DNA polymerase reaction by 66%, whereas at these concentrations each drug alone inhibited the reaction by 50 and 15%, respectively. However, the combination of chloroquine and primaquine at $500 \mu\text{g ml}^{-1}$ for each drug was not much more inhibitory than the lower concentrations (Table 2). The combination of chloroquine and quinacrine also showed moderately additive inhibitory activity against HB DNA polymerase. The combination of $500 \mu\text{g ml}^{-1}$ of chloroquine with 250 and $500 \mu\text{g ml}^{-1}$ quinacrine inhibited the DNA polymerase reaction by 71 and 78%, respectively (Table 2). In general the additive inhibitory effect of chloroquine combined with either primaquine or quinacrine was not much greater than the inhibition shown by the more active agent alone. The combination of chloroquine and chlorpromazine was quite effective in inhibiting the DNA polymerase reaction: $500 \mu\text{g ml}^{-1}$ of each drug combined inhibited the enzyme by 81% (Table 2). Chloroquine with methylene blue was an extremely potent inhibitory combination against HB DNA polymerase. Chloroquine at $500 \mu\text{g ml}^{-1}$ combined with 250 and $500 \mu\text{g ml}^{-1}$ of methylene blue inhibited the DNA polymerase reaction by 95 and 99.7%, respectively (Table 2). Primaquine combined with quinacrine also showed additive inhibitory effects against HB DNA polymerase (Table 2). The combination of quinacrine and chlorpromazine was extremely potent in inhibiting the DNA polymerase reaction; quinacrine $500 \mu\text{g ml}^{-1}$ combined with $100 \mu\text{g ml}^{-1}$ chlorpromazine inhibited the reaction by 84% (Table 2). Thus although the combinations of intercalators examined did not show synergistic effects, additive inhibitory effects were shown for all the drug combinations examined.

Of the three major antimalarial drugs examined primaquine was a much weaker inhibitor of HB DNA polymerase than either chloroquine or quinacrine. Primaquine seems to act as a preferential inhibitor of protein biosynthesis by causing a rapid breakdown of ribosomes when studied *in vivo*^{10,11}. Primaquine at $6 \times 10^{-4}\text{M}$ inhibits protein synthesis almost completely in *Bacillus megaterium* but has only marginal effects on the biosynthesis of DNA and ribonucleic acid¹⁰. The two phenothiazine derivatives, chlorpromazine and methylene blue, were quite active in inhibiting HB DNA polymerase. Careful study of the binding of these two compounds to DNA, in conditions selected to avoid precipitation of the DNA by the phenothiazine derivatives, by Allison and Hahn⁶ showed that these two drugs

Table 1 Comparison of inhibitory activity of intercalators against hepatitis B DNA polymerase

Intercalator	IC_{50} ($\mu\text{g ml}^{-1}$)
Ethidium bromide	3.2
Chloroquine	480
Quinacrine	334
Primaquine	900
Chlorpromazine	250

Reaction mixtures contained 0.15 M KCl and 0.01 M MgCl_2 without NP-40. Experimental details are given in the text and legend to Fig. 1.

Reaction mixtures contained 0.15 M KCl and 0.01 M MgCl_2 without NP-40. Reaction mixtures included the combination of drugs at the concentrations shown. Other experimental details as detailed in the text and in the legend to Fig. 1. CQ, chloroquine; PQ, primaquine; QC, quinacrine; CP, chlorpromazine; MB, methylene blue.

did bind to DNA in the manner of intercalators. Interestingly, neither quinine nor hydroxychloroquine were active inhibitors of the DNA polymerase. The observation that the various combinations of chloroquine, primaquine and quinacrine were only moderately more inhibitory than the more active drug in the combination suggested that the drugs all attach to the same site on the DNA. Inhibition of HBV DNA polymerase by the intercalators decreased as the concentration of MgCl_2 was increased. Magnesium interferes with the binding of intercalators to DNA⁴.

Our results show that hepatitis B DNA polymerase can be inhibited by drugs in clinical use. It has been suggested that the DNA polymerase of the hepatitis B virion plays an important part in the replicative cycle of this virus in the hepatocyte¹. Thus, our findings suggest a new approach to the therapy of HBV infection using intercalating agents either singly or in combination. Drugs such as chloroquine and quinacrine accumulate in very high concentrations in the human liver during therapy⁹, and this pharmacologic property may make it feasible to treat HBV infection, even though high concentrations are required to inhibit HBV DNA polymerase. Furthermore, the possible therapeutic effects of these template blocking agents may be examined in combination with DNA synthesis inhibitors or with interferon¹². Interestingly, intercalating agents have the singular property of eliminating bacterial plasmids^{13,14}. Thus it may be speculated that these compounds may remove and thus 'cure' the infected hepatocyte from HBV DNA. Clinical studies to evaluate the therapeutic possibilities of intercalating agents in human HBV infection are under way.

We thank Drs Salvatore Vernace, Fenton Schaffner and Martin Goldfield for providing sera from patients infected with HBV.

Relationship between β converting and γ non-converting corynebacteriophage DNA

BACTERIOPHAGE can convert non-toxin producing strains of *Corynebacterium diphtheriae* to toxinogeny, and the significance of the difference between β -tox⁺ converting corynebacteriophage isolated by Freeman¹ and γ -tox non-converting phage isolated in this laboratory² has been studied sporadically over the past 20 yr. These two phages are serologically related, but are heteroimmune when tested reciprocally against their lysogenic derivatives³. Both phages exhibit similar one-step growth characteristics and patterns of inducibility by ultraviolet light⁴ and are morphologically similar though differing slightly in head and tail measurements⁵. The phages recombine vegetatively, though at a frequency lower than in homoimmune β matings⁶ and also recombine as prophages in tandem double lysogens⁷. It has been shown⁸ that γ non-converting phage probably carries a cryptic tox gene, or part of the gene, as matings between β -tox and γ -tox have yielded tox⁺ recombinants. These data all suggest that there is a high degree of genetic homology between these two phages. To assess this point more directly we have examined DNA heteroduplexes of the phages and DNA fragments produced by various restriction endonucleases. The data show that the two phages are almost identical.

Heat-inducible mutants of β and γ phages, β -tsr3 and γ -tsr1, isolated in this laboratory⁹ were used for the production of purified phage DNA. These mutants are unlikely to vary significantly from wild-type phage because both are conditional lethals, presumably a result of point mutations and thus not detectably different from the wild type in heteroduplex analyses. Lysogens of these phages in strain C7 of *C. diphtheriae* were induced in tryptose yeast extract broth¹⁰ supplemented with 0.2% Tween 80. The phage were concentrated directly from lysates by high-speed centrifugation (100,000g) following an initial low-speed cycle (8,000g). The pellets were immediately resuspended in 0.05 M EDTA, 0.1 M NaCl, 0.05 M Tris buffer (pH 7.2) and the DNA was extracted sequentially, twice with equal volumes of chloroform:isoamyl alcohol (24:1). After dialysis against 0.006 M Tris (pH 7.5) the contaminating RNA was eliminated by a treatment for 1 h at 60 °C with ribonuclease (Calbiochem) at 0.05 mg ml⁻¹ in 0.01 M NaCl, 0.0005 M EDTA, 0.002 M Tris (pH 8.0). The purified DNA was then dialysed exhaustively as above. No contaminating bacterial DNA was detected in whole-phage DNA preparations subjected to Agarose gel electrophoresis. Melting profiles also demonstrated the homogeneity of the DNA preparations, and showed that the mole fraction of guanine plus cytosine in both β -tsr3 and γ -tsr1 was 0.54. These data, together with microscopic evidence, show that corynebacteriophage DNA is double stranded.

To determine the molecular mass of the phage genomes, whole phage DNA was prepared and mounted on grids for examination in the electron microscope by the Kleinschmidt technique¹¹. RSF2124, a 7.4×10^6 molecular mass derivative of the *Escherichia coli* plasmid ColE1 with an inserted Tn3 (provided by P. Shipley) was used as a molecular mass standard¹². The contour lengths of 21 linear β -tsr3 molecules were measured and from these a mean molecular mass of

Fig. 1 Electron micrograph of γ -*tsr1* DNA spread for the determination of molecular mass. The small molecular mass standard, RSF2124, is encircled by γ -*tsr1* DNA.

$22.9 \pm 0.31 \times 10^6$ (\pm standard error) was calculated. Similarly, 20 γ -*tsr1* molecules had a mean molecular mass of $25.2 \pm 0.51 \times 10^6$. These data compare favourably to the estimate of 22×10^6 for wild-type β DNA reported by Wolfson and Dressler (quoted in ref. 13). Circular molecules noted in these preparations (Fig. 1) were also measured. The molecular mass as calculated from the contour length of 21 circular β -*tsr3* molecules was $22.9 \pm 0.08 \times 10^6$, and was $24.9 \pm 0.07 \times 10^6$ for 19 circular γ -*tsr1* molecules. The presence of circular molecules in the DNA preparations suggests that packaged β and γ phages have sticky, single-stranded ends similar to the lamboid phages of *E. coli*. Laird and Groman, in their study of the prophage map of β phage⁷, postulated that circularisation of the vegetative phage genome precedes integration into the bacterial genome. Our findings provide physical evidence that this step is possible.

Heteroduplexes of the two corynebacteriophage mutants

were prepared¹⁴ and examined in the electron microscope. Two typical heteroduplexes are shown in Fig. 2a. Three single-stranded regions of nonhomology were observed, two deletion-insertion loops (DI-1 and DI-2) and one substitution bubble (S). Preliminary calculations showed that the two single-stranded DI loops were most reasonably assigned to γ (see below), and therefore the total duplex length of the hybrid molecule plus the length of S was attributed to β . With the duplex length of β , the molecular mass of its DNA and a conversion factor of 2.08×10^8 per μm (ref. 15), the absolute sizes of various segments of DNA in the heteroduplex were readily calculated. The end of the heteroduplex nearest to the DI-1 loop was arbitrarily chosen as the starting point, and the distances derived are shown in Fig. 2b. Loops DI-1 and DI-2 were assigned to γ -*tsr1* because the sum of these loops, 2.0×10^6 , corresponds closely to the 2.3×10^6 difference in the molecular mass of the two bacteriophage DNAs.

The most significant finding in these heteroduplex studies is that over 99% of β DNA is homologous to γ DNA. Only the 0.11- μm S segment fails to hybridise. Conversely, if the sizes of DI-1, DI-2 and the estimated length of β are summed to give the approximate size of γ , it can be calculated that over 91% of γ DNA is homologous to corresponding regions of β DNA. The DI loops were assigned to γ in these calculations. Further evidence of this close relationship is provided by the electrophoretic banding patterns of restriction enzyme digests of the two phage DNAs. DNA from β -*tsr3* and γ -*tsr1* was cleaved with restriction enzymes and the resulting fragments were compared by electrophoresis on Agarose gels¹⁶. The gels show that β and γ have remarkably similar patterns, although in all digests γ DNA displayed one or more bands not found in β DNA (Fig. 3).

The heteroduplex of β and γ DNA establish unequivocally that there is a close evolutionary relationship between these two phages, a conclusion previously suggested by circumstantial genetic, serological and morphological data. The restriction enzyme analysis also strongly

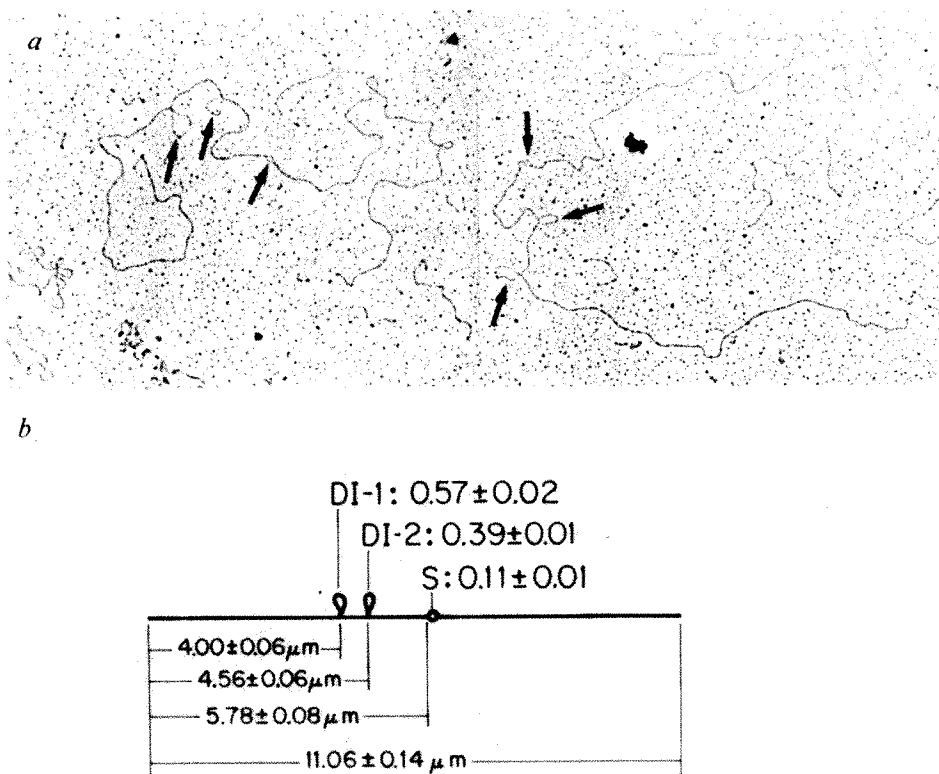

Fig. 2 a, Heteroduplexes between β -*tsr3* and γ -*tsr1*. Heteroduplexes were prepared by mixing 0.1 to 0.2 μg of each DNA in 0.25 ml of a 0.1 M NaOH, 0.01 M EDTA aqueous solution at pH 12.4–12.6 for 10 min, at which time the pH was reduced to 8.4–8.6 by adding 2.0 M Tris (pH 7.1). Formamide, 0.25 ml, was added and the mixture allowed to re-anneal at room temperature for 4–6 h at which time the DNA was spread and rotary shadowed as described¹⁴. All electron microscopy was done with a JEOL Model 100B electron microscope. b, Graphical representation of the heteroduplex.

Fig. 3 Restriction enzyme digests after electrophoresis on 0.5% Agarose gels. *a*, *Sal*I; *b*, *BAM* H-1; *c*, *Eco* R1. In each case the γ -*tsr*1 DNA is in the left lane and the β -*tsr*3 DNA in the right lane. One minor band that appears at the bottom of the negative for the *Sal*I digest of both γ and β does not appear in this photograph.

supports this conclusion. The high degree of similarity seen in the DNA pattern of the digest is more significant than the differences, since small changes in nucleotide sequences (including single base changes) can alter DNA banding patterns. The presence of one or more minor bands in the Agarose gels (Fig. 3) indicates that there is a small amount of heterogeneity in the digests of γ DNA. Since this heterogeneity was not eliminated by clonal reisolation it is assumed to be intrinsic to the γ population. The reason for this heterogeneity is not clear, but the limited nature of this variation does not affect the primary conclusions of this paper.

Data from the restriction enzyme digests also confirm the molecular mass of β and γ DNA obtained by direct measurement. Standards were used to calculate the approximate masses of each fragment in the digest and these were summed to provide an independent estimate of the size of the two phage DNAs. In the three digests used in these calculations, β -*tsr*3 varied in size from 21 to 22×10^6 and γ -*tsr*1 varied from 22 to 23×10^6 . Although these figures are slightly smaller than those reported above from direct measurements, they are confirmatory, particularly since the summation of fragment weights is less precise than calculations from contour length. Significantly, in each enzyme digest γ DNA was consistently 1 to 2×10^6 molecular masses larger than β . This closely approximates the size differences calculated from the direct measurements.

On the basis of previous observations (see above), a large degree of homology was expected between β -*tsr*3 and γ -*tsr*1. However, it is of particular interest that though these phages are heteroimmune their DNAs are 99% homologous. This suggests that parental β and γ phages are either recent evolutionary derivatives, one from the other, or recently shared a common ancestor. If so, then heteroimmunity must have arisen either through a small number of muta-

tions or through recombination with a distantly related corynephage. Strong selective pressure for genes outside the immunity region would also account for the high degree of homology, but the extent of homology makes it less likely that this is the primary conserving mechanism.

It is not possible to identify the regions of nonhomology between β and γ phages without appropriate mutants. Because these phages are heteroimmune the immunity region is an obvious candidate for the region of nonhomology seen in the substitution bubble. Although β phage is *tox*⁺ and γ is *tox*, it is known that γ carries at least a portion of the *tox* gene⁸. It is possible that the cryptic nature of the *tox* gene in γ is the result of an insertion of nonhomologous DNA into the *tox* gene. If this were the case it would account for one or both of the loops.

We thank Mr Ron Gill for his advice on techniques and helpful discussions. This research is supported by USPHS grant AI-10492 and NSF grant 75-14174.

CIDNP in tyrosyl protons of luliberin

We report here on the possibility of extending CIDNP (chemically induced nuclear magnetic polarisation)-assisted NMR studies of the tyrosyl unit to medium sized peptides. Our previous studies indicate that, strong ¹H nuclear polarisation may usually be obtained in phenols in the presence of dyes such as fluorescein or any of its halogenated derivatives, such as rose bengal, erythrosin B or eosin Y, and others excited to their triplet state¹⁻⁴. The polarisation is due to the H atom transfer from the hydroxyl of the phenol ArOH to the triplet excited dye ³D,

and back,

Steps (a) and (b) were shown to be chemically reversible, the nuclear polarisation resulting from the magnetic interactions in spin-correlated radical pairs ArO[•] + DH[•].

We recently reported that the phenolic amino acid tyrosine and some of its simple derivatives as well as small tyrosyl peptides show a similar phenol CIDNP in certain well defined conditions⁵ (Dr R. Kaptein (Groningen) has performed similar

Fig. 1 (—) ^1H 90 MHz FT NMR spectra of luliberin acetate (0.01 M) in D_2O in the presence of fluorescein (2×10^{-3} M). Broken lines (---) give the integration curves. Each spectrum is the result of 256 accumulated pulses. *D*, dark spectrum; *L*, light spectrum (RF pulse preceded by 1 s ultraviolet irradiation period). The protons are assigned according to Vessel *et al.*⁸ *a-d*, aromatic rings: *a*, His; *b*, Trp; *c*, Trp and Tyr meta to OH; *d*, Tyr ortho to OH; *e* and *e'*, HDO impurity; *f*, methylene of Gly-NH₂; *g*, Ser methylene; *h*, Tyr, His, Trp and Arg methylene; *i*, Glu and Pro methylenes; *j*, acetate; *k*, Leu and Arg methylenes; *l*, Leu methyl; TMSP, trimethyl silyl propanoic acid, d_4 used as $\delta = 0$ standard.

tyrosine CIDNP studies with other unspecified dyes). In our studies, carried out in D_2O solutions in the presence of fluorescein, strong CIDNP effects were obtained on the tyrosine ring protons ortho to the OH group and on the tyrosine methylene protons.

The particular substrate chosen in this investigation of the triplet dye-induced tyrosyl CIDNP in peptides was luliberin^{6,7}, the hypothalamic luteinising hormone releasing factor (LRF). This linear decapeptide of amino acid sequence pGlu-His-Trp-Ser-Tyr-Gly-Leu-Arg-Pro-Gly-NH₂, was used as the acetate after repeated exchange of its acidic protons with D_2O .

Figure 1 (*L*) shows the effect of ultraviolet irradiation on the proton NMR spectrum of a 0.01 M solution of luliberin in D_2O in the presence of fluorescein (0.002 M), which acts as the H atom photoabstractor. The tyrosyl ring protons ortho to the hydroxyl group (*d*) show a 17-fold negative enhancement *E*. Signal *h*, due to the tyrosyl methylene protons and to methylene protons of His, Trp and Arg⁸ similarly shows a 2-fold enhancement (*A*). The signs of the CIDNP effect for ortho and methylene protons (— and +) are the same as those found in the other phenols¹⁻³, in complete agreement with the analysis

based on the radical-pair model of CIDNP⁹. The *E* and *A* effects in luliberin are similar in magnitude to the effects observed in other tyrosine compounds with the exception of H-Tyr-Tyr-OH, where considerably larger effects were observed (ref. 5 and K. A. M. & C. G., in preparation). The two synthetic derivatives¹⁰ [*L*-Ala⁶]LRF and [*D*-Ala⁶]LRF were also studied, and gave almost identical results.

Preliminary results in smaller peptides indicate that tyrosine ^1H CIDNP is strongly pH dependent. This effect should probably be attributed to the nuclear relaxation of the polarised nuclei catalysed by fast degenerate electron exchange processes (* denoting nuclear polarisation)

and

The efficiency of these is due to the short T_1 relaxation times of the paramagnetic species $\text{Ar}^*\text{O}^\bullet$ and $\text{Ar}^*\text{OH}^{+\bullet}$.

Further experiments are being carried out to determine the scope of the method and the role of factors such as structure of peptide and of photoabstractor, and tyrosyl unit accessibility.

Nature Index and Binders

The complete Index for 1976 is available, price £2.50 (UK), US\$5.00 (Rest of World). Copies of the 1975 index are still on sale, price £2.25 (UK), US\$5.00 (Rest of World).

Binders for the journal are also available at £8.00 (UK), US\$16.00 (Rest of World) for three: a year of *Nature* fits into three binders.

All prices include postage. Payment may be made in any currency at the prevailing exchange rate. Orders should be sent, accompanied by remittance, to Macmillan Journals Ltd, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

matters arising

Upwelling by icebergs

NESHYBA¹ argues for the importance of iceberg melting below the thermocline in introducing nutrient rich water into the surface layer. I believe she overrates this effect. She assumes that icebergs melt as a single piece and does not even consider calving as part of the deterioration process. Icebergs that are protected from wave action by sea ice are observed to deteriorate little. Icebergs begin to undergo rapid deterioration when they emerge from the sea ice into the open sea². Wave action progressively melts a groove at the waterline by turbulent mixing. I have observed these grooves to have a depth of up to 7–10 m. The sides of the iceberg then fail, producing a large number of small icebergs and 'growlers' and much fine brash. These small icebergs and growlers, which in most cases would be less than 30 m long and have a maximum draft of 20–25 m, are subject to the same erosional forces. Although no hard figures exist at this time, I would estimate that more than 80% of the melting of an iceberg takes place in a surface layer no deeper than 20 m which is in most cases shallower than the main thermocline.

Cadmium in seabirds

I FEEL that the article on cadmium in marine animals by Bull *et al.*¹ contains a number of misstatements. Seabirds do not generally contain higher residues than marine invertebrates; as long ago as 1956 Mullin and Riley² reported that molluscs may contain up to 500 mg of cadmium per kg in their digestive organs and renal glands, a level not yet equalled by birds, and Holdgate³ reported much the same levels in healthy guillemots *Uria aalge* from British waters as Bull *et al.*¹ do for other marine animals.

Anderlini *et al.*⁴ only investigated six, not seven, bird species, and then only looked at the eggs, which contain little cadmium, for three of them; they included birds from the Atlantic as well as the Pacific and Antarctic. In the three

species where they tested the livers, the most novel finding was perhaps not so much the presence of a mean level of 53 mg of cadmium per kg in ashy petrels *Oceanodroma homochroa* from the polluted coast of California, as that of nearly half as much (means of 20–28 mg per kg) in the livers of snow petrels *Pagodroma nivea* resident in the Antarctic pack ice and Wilson's petrels *Oceanites oceanicus* breeding in Antarctica and migrating into different northern oceans. Similarly, the main point of interest about the puffins *Fratercula arctica* examined by Parslow *et al.*⁵, only one of which was taken alive at a colony as reported by Bull *et al.*¹, was that the two healthy birds from remote west coast colonies contained much more cadmium than the six mainly found washed up on beaches from the east coast. They also reported surprising levels in a herring gull *Larus argentatus* (12 mg per kg) and a Manx shearwater *Puffinus puffinus* (24 mg per kg) as well as the fulmar *Fulmarus glacialis* liver level of 159 mg per kg actually quoted by Bull *et al.*¹ which is higher than any reported by the latter from the same laboratory when they claimed 'considerably higher levels than any previously found'; the ashy petrel mean is in fact also near their highest liver level.

In addition to their references to past evidence for the normal occurrence of high cadmium levels in pelagic seabirds, Bull *et al.*¹ also seem a little careless in their discussion of their own observations on the occurrence of cadmium in sea-skaters *Halobates micans*. They state 'some of the areas where the higher cadmium residues occur, for example off the coast of West Africa,

have little industrial activity, but have upwelling currents of cold water which bring to the surface nutrients, and possibly cadmium too. Areas of ocean upwelling are known to be important wintering locations for pelagic seabirds.' Leaving aside the question whether the bird species quoted do in fact winter in upwelling areas, the map published by Bull *et al.*¹ shows no particular concentration of cadmium in *Halobates* in such areas, but in fact an apparently random distribution of levels above 25 mg per kg throughout the area sampled including the centre of the Sargasso Sea, which is more celebrated for sinking water than upwelling.

Bull *et al.*¹ attribute to me the statement that individual birds are becoming increasingly contaminated with cadmium through feeding in areas of local pollution around the British coast. In point of fact, I ended the paragraph which I devoted to cadmium⁶ 'it would appear that like some other marine animals pelagic seabirds may accumulate exceptional amounts of this element, whose effects are still obscure'. This statement attributed to me comes from the next paragraph summarising observations of heavy metals in general, though as Holdgate³ reported up to 13 mg per kg cadmium in dead guillemots washed up in western Britain in the autumn of 1969 when the level in normal birds was low, it seems possible that there may be some local pollution with cadmium as well as other metals of birds frequenting our offshore waters. If this is the case with either cadmium or any other pollutant it seems doubtful whether it will be detected by looking at birds from remote breeding stations which feed elsewhere, rather than at individuals dying on the spot. It would also be helpful if Monks Wood Experimental Station could place all their other estimations of pollutants on record.

Matters Arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered.

Transmitter release statistics are meaningful

BARTON and Cohen¹ recently attempted to show that statistical analyses of neurotransmitter release, especially those based on a simple binomial model, are of dubious validity. Given their point of view, the authors might have asked: are any statistics meaningful? Every statistical analysis is based on certain assumptions, some purely formalistic, some containing empirical elements. If the statistician assumes an underlying binomial distribution then he tacitly assumes that there are a number of units, each of which may act independently in two ways with a certain probability for each way, the respective values for these probabilities being the same for all units. A binomial assumption was first satisfactorily applied to transmitter release at the crayfish neuromuscular junction². In general terms such an analysis assumes units involving a certain class, C , of probability distributions. The basic parameters of this class are (1) the form of dependence of the units; (2) the number of units, n ; (3) the probabilities of release, p_1, p_2, \dots, p_n . The binomial is the simplest subclass of the whole with independence, n constant and $p_1 = p_2 = \dots = p_n$. Each element of this subclass can be approximated in many ways by more complicated elements of C , but is there any value in that when the simplest analysis suffices?

For example, in the case of falling bodies a random exponent, distributed about 2.00001, would serve as well as the classic quadratic relation; orbits other than a simple ellipse could suffice to describe the path of the earth around the sun.

These examples illustrate the 'principle of parsimony' which postulates that one's observations be described by as simple a model as possible. Experimental observations which cannot be described by the simplest model can then be used for gaining insight into the underlying processes in the real world and are described by, stepwise, more complex models (for example, the branch-block model proposed to explain experimental findings at the frog neuromuscular junction³).

The computed example of Barton and Cohen presents the result of a concatenation of binomial trials with a wide range of p values. However, it is difficult to conceive that over 100 quanta with such low release probabilities ($p < 0.01$ in over 70% of quanta) would result in so few failures of release (their Fig. 1b shows only 2–3 failures). Nonetheless, in the result as presented, the simulated and predicted curves would seem to be different; indeed, the χ^2 value quoted indicates that, had they simulated about 250 trials instead of 100, a 5% level of significance would have been achieved with the same relative differences between

the two histograms. This emphasises the importance of an adequate number of samples for satisfactory analysis of transmitter release.

We find the paper of Barton and Cohen a negative one, which makes no contribution to the real need, of which our own experimental results have made us particularly aware. This need is for a comprehensive theoretical treatment of particular generalisations of the binomial model, of which the branch-block model is simply one. Only then will interpretation of experimental results be soundly based; but without the experiments science can become merely a meaningless play with models.

E. HANSERT
A. WERNIG
J. J. CARMODY

Max-Planck-Institut für Psychiatrie,
D-8000 München 40,
Kraepelinstraße 2, FRG

1. Barton, S. B. & Cohen, I. S. *Nature* 268, 267–268 (1977).
2. Johnson, E. W. & Wernig, A. J. *Physiol., Lond.* 218, 757–767 (1971).
3. Carmody, J. J. & Wernig, A. *Pflügers Arch. ges. Physiol.* R32 (1977).

BARTON AND COHEN REPLY—We indicated¹ that many different p distributions can lead to histograms of the quantal content which are indistinguishable from the binomial predictions. There are a number of reasons for rejecting the plea of Hansert, Wernig and Carmody that only the 'simplest analysis' should be considered. As we mentioned in our letter, the binomial assumption conflicts with at least two experimental observations. First, quantal contents greater than the binomial estimate of n have been recorded at the crayfish neuromuscular junction; this is equivalent to a release of more than the total number of available quanta. Second, the timing of spontaneously released quanta is clustered, implying temporal or spatial non-uniformity of the release process. It is not obvious how the branch-block modification can explain this property of spontaneous release.

The implications of statistical analyses of quantal release are critically dependent

on the assumed probability distribution. n is generally assumed to represent an extensive property of the release process and p an intensive one. However, if the binomial assumption is false then a change in the p distribution of a fixed number of quanta would be interpreted as a change in both n and p , or even as a change in n alone.

The principle of parsimony is used to select the simplest of a set of equivalent hypotheses². However, this principle is irrelevant because the predictions of the assumptions in question are different and experimental distinction of these hypotheses is possible.

We would like to clarify three other points raised by Hansert *et al.* First, there are only two failures of release when 70% of the quanta have $p < 0.01$ because those quanta with high p values effectively prevent large numbers of failures. If a single quantum had $p = 1$ then no failures would ever occur. Second, we described a simulation of 100 trials—a sample size often used by some workers³—but simulations of 1,000 trials produced similar results (see Table 1). It is incorrect to assume, as Hansert *et al.* did, that the relative shape of the quantal-content histogram remains the same when the sample size is increased. After publication of our letter it was brought to our attention that Brown, Perkel and Feldman⁴ had performed a similar analysis in 1976 and had reached the same conclusions that we did; they used 1,000 trials and studied the effects of temporal and spatial variations in n or p . The distributions of quantal contents remained indistinguishable from the binomial predictions even at this high sample size. Third, we agree that a general theoretical treatment would be valuable, but the successful development of this seems unlikely without more data.

These arguments suggest to us that the assumption of binomial release is unlikely to be valid, despite its mathematical simplicity. We believe that the contribution of our letter can be determined only by its success or failure in stimulating new experiments designed to differentiate between the various hypotheses.

STUART B. BARTON

Table 1 The results of six simulations

χ^2	Degrees of freedom	P
5.421	7	0.61
0.924	5	0.97
6.921	6	0.34
3.094	8	0.93
8.172	6	0.23
9.305	6	0.16

The distribution of the release probability of the 100 quanta was generated in the same way as that in Fig. 1a of our earlier letter¹ ($\bar{z} = -5$, $\sigma_z^2 = 2$). 1,000 trials were performed in each simulation. The χ^2 value compares the simulated distribution of quantal contents with the best-fitting binomial distribution. The P values give the probability that a value of χ^2 greater than the observed value can arise by chance.

Elucidation of the structure of glyco-protein carbohydrate moieties is important in order to understand their physiological role. Exoglycosidases have been widely used as tools for the structural study of glycoproteins degrading the sugar chain from the non-reducing end. They reveal the sequence in oligosaccharide chains and also the anomeric configuration based on the specificity of the glycosidase for α and β linkages.

Endoglycosidases releasing oligosaccharides are now also available and suitable for studies on glycoproteins and glycopeptides with complex sugar chains. These enzymes are highly purified and specific proteins.

Send for your copy of the Miles Research Products Catalog describing these and many other significant Research Biochemicals.

New Titles on Membranes and Lipids

Handbook of Lipid Research

Treatise edited by Donald J. Hanahan

This new series offers expert reviews of research involving fatty acids and glycerides, phospholipids, sphingolipids, the sterols, steroids, and physico-chemical facets of lipids.

Volume 1: Fatty Acids and Glycerides

edited by Arnis Kuksis

Summarizes current methodology and research findings in fatty acid and acylglycerol separation, determination of structure, and methods of chemical synthesis. approx. 440 pp., illus., 1978, \$42.00/£22.05

Volume 2: The Fat-Soluble Vitamins

edited by Hector F. DeLuca

Reviews the mechanisms of absorption, distribution in nature, metabolism, and mechanism of action of the fat-soluble vitamins, and their relation to disease. approx. 315 pp., illus., 1978, \$33.00/£17.33

Methods in Membrane Biology

edited by Edward D. Korn

Volume 9

Describes recent developments in physical methods for studying membrane lipids—scanning calorimeters, paramagnetic hydrophilic probe on the NMR signal, and the genetic approach. 407 pp., illus., 1978, \$42.00/£22.05

Volume 8

Examines chemical and physical methods for characterizing lipids, organic solvents used to separate membrane components, chemical synthesis of stereospecific lipids, and electron paramagnetic resonance spectroscopy. 378 pp., illus., 1977, \$39.00/£20.48

Function and Biosynthesis of Lipids

edited by Nicolás G. Bazán,

Rodolfo R. Brenner, and Norma M. Giusto

This volume examines lipid involvement in the biogenesis of membranes; glycosphingolipids and gangliosides; lipids in the central nervous system; and the enzymology and role of fatty acids. *Advances in Experimental Medicine and Biology, Volume 83.* 658 pp., 1977, \$71.40/£37.49

Lipid Metabolism in Mammals

edited by Fred Snyder

In two volumes

Destined to become the standard reference source of lipid metabolism in mammals, this two-volume treatise emphasizes the uniqueness of lipid pathways in the different organs of the body. Volumes in *Monographs in Lipid Research*.

Volume 1: 420 pp., 1977, \$51.00/£26.78

Volume 2: 408 pp., 1977, \$51.00/£26.78

The Molecular Biology of Membranes

edited by Sidney Fleischer,

Youssef Hatefi, David MacLennan,

and Alexander Tzagoloff

Examines an important area of biochemical research today—mitochondrial structure and metabolism. approx. 330 pp., illus., 1978, \$35.40/£18.59

Physiology of Membrane Disorders

edited by Thomas Andreoli,

Joseph Hoffman, and Darrell D. Fanestil

Provides a comprehensive assay of the pathophysiological disturbances of membrane structure and function. approx. 1395 pp., illus., 1978, \$90.00/£47.25

Phylogeny of immunity

Nicholas Cohen

Immunity in Evolution. By John J. Marchalonis. Pp.xx+316. (Edward Arnold: London, 1977.) £10.

RECENT years have witnessed a surge of quality research and heightened theoretical interest in the plethora of problems posed by the phylogeny of immunity. Within the past two years, this activity has led to the birth of the journal, *Developmental and Comparative Immunology*, and to the formation of the Division of Comparative Immunology within the construct of the American Society of Zoologists. This activity has also been translated into several reviews, publication of the proceedings of four substantive international symposia, and, as well might be expected, the appearance of three monographs. Dr Marchalonis' labour of love, *Immunity in Evolution*, is the most recent single-authored volume to appear. Fortunately, for readers and authors (and publishing companies), redundancy has been minimised, since each monograph vividly mirrors its author's unique interest, expertise, and personality.

Marchalonis devotes a full 10 chapters to a discussion of the evolution of immunoglobulin structure and function, an area in which his first-hand experience and insight is well-known. Following a detailed review of the structure of mammalian immunoglobulins and the arrangement of immunoglobulin genes in mammals, Marchalonis digests, in a well organised and well written fashion (and in separate chapters) the large body of literature dealing with invertebrate humoral mediators of defense; the phylogenetic emergence of IgM; light chains; the distribution of immunoglobulins distinct from the IgM class; variable regions; antigenic studies of immunoglobulins of eutherian mammals; molecules that might possibly be related to immunoglobulins; and the origins of antibody diversity. His text is more than a paraphrasing of the original papers; it is an assimilation that focuses on concepts and enigmatic problems as well as on facts.

Although Marchalonis does not deal with the evolution of the cellular basis of immunity with the same detail and

perceptive depth that he devotes to humoral immunity, he does critically discuss many of the salient aspects of quasi-immune recognition and effector systems of invertebrates; the emergence of lymphoid cells and organs; the phylogenetic distribution of cell-mediated immune functions; memory and tolerance; and manipulations of the immune systems of ectothermic vertebrates with temperature. It is in these chapters, however, that one shortcoming of the book emerges, a blemish that is revealed only because of the very vitality of the field with which it deals. Although fewer than 2% of the more than 700 cited references were published in 1975 (none were later), it is precisely during the past three years that many of the queries commendably raised by Marchalonis that bear, for example, on the evolution of lymphocyte heterogeneity, the evolution of the major histocompatibility complex, cell cooperation, and the selective effects of temperature on a subset of T cells, have been approached and partly answered. It is also during this period that major concepts in cellular immunology have emerged that may have striking ramifications in understanding the evolution of immunity

(for example, associated recognition). In short, the time from submission and revision of the manuscript to its publication this year was too long.

Fortunately, it is relatively easy for the interested reader to remedy this understandable problem. He or she need only peruse one of the recent photo-offset published proceedings of the symposia held in 1975-77 (*Developmental Immunology*, *Am. Zool.*, **15**, 3-213; 1975; *Immunologic Phylogeny*, ed. W. H. Hildemann and A. A. Benedict, *Adv. exp. Med. Biol.*, **64**, Plenum: New York; 1975; *Phylogeny of Thymus and Bone-Marrow-Bursa Cells*, ed. R. K. Wright and E. L. Cooper, North-Holland: Amsterdam; 1976; *Developmental Immunobiology*, ed. B. M. Solomon and J. D. Horton, North-Holland: Amsterdam; in press) to update their information. Marchalonis' book has provided many of the provocative questions and has predicted several experimental scenarios; these symposia provide at least some of the answers. □

Liquid semiconductors

Liquid Semiconductors. By Melvin Cutler. Pp. 226. (Academic: New York and London, 1977.) \$19.50; £13.85.

PHYSICISTS weaned on the nearly-free-electron theory of solids find it satisfying, if at first surprising, that the properties of most liquid metals can be treated within this approximation. As long as the scattering of the conduction electrons by the non-crystalline arrangement of atoms is weak, perturbation theory can be used, as for example in Ziman's theory of electrical conductivity. It seems that many of the recently discovered metallic glasses can also be described in these terms. However, if the scattering is so strong that the mean free path becomes comparable to the average lattice spacing, then perturbation theory is no longer adequate and new approaches must be sought. This is the situation in certain liquid

metals and in all amorphous and liquid semiconductors.

Concepts required for an understanding of the physics of amorphous and liquid semiconductors have evolved over the past ten years. It is clear that many properties are determined by the short range or local configuration of atoms—that is, bond length, bond angle and coordination number. These determine the main features of the distribution in energy of the electronic states. It is quite proper, therefore, that the author of this book should stress the tight-binding or molecular-bond model when interpreting experimental behaviour. Electrical conductivity, Hall effect and other transport properties demand special treatment, since the concept of well defined wave vectors for the electrons becomes inappropriate and the relaxation time approximation breaks down. The author describes the

current level of understanding of these properties, calling for the most part on models developed to describe amorphous semiconductors. For liquids, of course, further difficulties arise. The local atomic configuration and hence the electronic structure changes not only with time but also with temperature. Thus, if measurements are made as a function of temperature, one has to deal with a different material at each temperature.

The field is not short of experimental results and these are presented in several chapters, one devoted to physical properties, one to physico-chemical properties and metallurgical properties, and two others to specific alloys. The book is valuable for this collection alone. It is not surprising to find Ti-Te alloys discussed extensively, since this system has not only been exhaustively investigated by the author himself, but also exhibits so many of the diverse and interesting properties characteristic of liquid semiconductors. Experimentalists will appreciate the short chapter on techniques.

It behoves a reviewer to draw attention to faults lest it be thought that he is a friend of the author (which he is) or else in league with the publishers (which he is not). My only criticism (apart from an unfortunate interchange of the words band and bond between two section headings in the list of contents), is that tantalising extracts of theory and models, described in detail in later chapters, are interspersed with experimental data presented earlier in the book; yet if the reader tries the theoretical chapters first, he is confronted with tantalising extracts of data. One has to learn, however, to find one's way around any book of this kind and specialists in the field will certainly have no trouble.

The price came as a pleasant surprise (by today's standards) and the book *has* to be good value for such an admirable condensation of a difficult subject by a leader in the field.

Group theory or general relativity

Group Theory and General Relativity. By Moshe Carmeli. Pp. 391. (McGraw-Hill: New York and Toronto, 1977.) £16.85.

THERE is no doubt that a textbook which links together the topics of group theory and general relativity is very welcome. The jacket of this book proclaims that it is the first book on "the applications of group theory to general relativity", but I have some reservations about whether this is an appropriate description. Reading the book gives the impression of two research monographs grafted together: one on group theory, the other general relativity. This does not mean that the contents are not useful, but some stronger motivation for the conjunction of topics would have been desirable.

Field theoreticians are well used to relying heavily on group theoretical techniques, particularly with the recent activity in the area of gauge theories. When it comes to general relativity, group techniques are less powerful because of the absence in general of metric-preserving global diffeomorphisms. Of course, interest centres on special model spacetimes with particular symmetries, and group theory has long played an elegant and useful role in elucidating and classifying their properties. More general classes of

spacetimes, however, can be fruitfully investigated using group methods. Especially important are those that admit asymptotic symmetry groups, and the formulation of concepts such as asymptotic energy momentum, and multipole moments of the gravitational field for isolated bodies relies heavily on the analysis of these groups. In addition to this, much attention has recently been directed to gauge theories in curved spacetime, in which the gauge group continues to play an important part.

This book covers much of the material relevant to these applications, but in a somewhat shapeless form. Readers who have no previous knowledge of one or the other (or both) central topics may find the presentation a little stark with essential facts simply run off. I would recommend some previous background reading, at least for the group theory, from the books of Naimark or Gel'fand *et al.* These are recommended by the author in his introduction, and Carmeli's treatment is closely similar to these.

The first six chapters contain little general relativity, dealing extensively with the representations of the rotation and Lorentz groups. Chapter 3 treats the spinor representations of the Lorentz group. Chapters 4, 5 and 6 tackle in great depth the principal, complementary and complete series of representations of $SL(2, \mathbb{C})$.

The author's discussion of relativity begins with chapter 7. The treatment is standard and traditional, and no attempt seems to have been made to

present the material in any especially novel or enlightening way, or to exploit many of the techniques of modern differential geometry. It is here that one most feels the need for stronger links with the group theory and motivating remarks. The author goes on to develop a detailed discussion of the spinor formulation of general relativity, and it is particularly useful that this approach, advocated by Roger Penrose, and for so long in widespread use among relativists, is dealt with in an integrated fashion in a student textbook. It is frustrating, though, that many useful results of spinor calculus are relegated to the exercises.

In chapter 9, Carmeli takes up the subject of gauge theories, and after a preliminary discussion of electromagnetic and Yang-Mills fields attempts to formulate general relativity also as a gauge theory. The Newman-Penrose formalism is obtained from a gauge theory approach, though perhaps its physical relevance could have been better described. The Goldberg-Sachs theorem is proved in chapter 10, but its importance is not made transparent.

The final two chapters of the book deal with solutions of the field equations of general relativity and the Bondi-Metzner-Sachs group. There are also several appendices. Once again, all the details are competently collected together, but the uninitiated reader may have difficulty in understanding their wider importance or relevance. Perhaps these people would do well to consult the final paragraph of the Introduction which contains a quotation of Abdus Salam, who learned group theory from Racah: "After attending these lectures I thought this is really too hard; I cannot learn this; one is hardly ever likely to need all this complicated matter. I was completely wrong".

In spite of the specific criticisms concerning the presentation, I find this book a timely addition to the many research papers on these two most important topics. It should prove useful as a teaching text and, at least in conjunction with some background material, it could be used as a course book for either group theory for physicists, or more specifically for relativity courses. The style is straightforward and information retrieval easy. Many exercises are given with each chapter and an extensive bibliography is added. It is elegantly produced, and at £16.85 is not over-expensive for a mathematical book of this length.

Announcing a New Journal . . .

INVESTIGATIVE AND CELL PATHOLOGY

This Journal is an independent, international periodical which will be published quarterly. It aims to provide a forum for original papers concerned primarily with the correlation of structure and function in normal and pathological tissues.

Within this context, the Journal will cover all aspects of investigative pathology and experimental medicine. Original articles concerned with cell biology, embryology and teratology in relation to human disease will be encouraged. Contributions concerned with animal models of human disease, new techniques, tumour pathology, iatrogenic and metabolic disease will also be included.

Each issue will contain signed editorials on topical or controversial aspects of investigative and cell pathology, together with one or more review articles related to areas of current interest. Letters to the Editor and reviews of recently published books will also become a regular feature of the Journal.

NONCOHERENT OPTICAL PROCESSING

by G. L. Rogers, *University of Aston in Birmingham, UK.*

This explores the theoretical developments of noncoherent optical processing techniques refined over the last decade, and presents a detailed analysis of the relation between coherent and noncoherent systems, providing a theoretical and philosophical framework for the noncoherent techniques. It introduces a new field of virtually unexplored possibilities, including methods of preselection and information on coding and decoding techniques. Basic concepts of redundancy, spatial frequencies, parallel processing, orthogonality in optics, and spatial and temporal modulation are presented. (Wiley Series in Pure and Applied Optics).

FLORA OF THE USSR Vol. XXI, Labiatae, Part 2

edited by B. K. Shishkin, *Komarov Botanical Institute, USSR Academy of Sciences.*

Translated from the Russian.

This concludes the description of the family Labiatae, covering another 44 genera and 544 species. Two new genera, *Metastachys* Knorr, and *Gontscharovia* Boriss, and several new species are described here for the first time. Species of the genera *Thymus* and *Ziziphora* are dealt with in great detail. The plants described in this volume include many oil-producing and medicinal species and those utilized in the food industry. (Series: Flora of the USSR).

FUNCTIONAL NEUROSCIENCE Vol. 1: Foundations of Cognitive Processes and Vol. 2: Neurometrics: Clinical Applications of Quantitative Electrophysiology.

by R. Thatcher and R. John, both of *New York Medical College.*

Volume one is an integration of basic neurophysiological, neurochemical, and electrophysiological data as applied to higher mental functioning, particularly in regard to applications. Part 1 is concerned with the integration of neuroanatomical, neurochemical and neurophysiological processes.

Volume two describes a revolutionary technique for assessing brain functions particularly related to information processing and higher cognitive functionings. It presents a comprehensive review of research in electrophysiology and defines the inadequacy of existing methods for assessing brain functions. (Series: Functional Neuroscience).

MOLECULAR GENETIC MODIFICATION OF EUKARYOTES

Edited by IRWIN RUBENSTEIN, RONALD L. PHILLIPS, CHARLES E. GREEN and ROBERT J. DESNICK

FROM THE PREFACE:

The editors hope that this book will serve to collect in one volume some independent judgments on the potential of molecular genetic modification, assess some of the tools at hand for such research, expose the more obviously deficient areas of knowledge, and present additional data. . . . Throughout the book the usefulness of molecular genetic techniques is obvious in three aspects; as an alternative approach to currently available genetic methods, as a new approach to currently unfeasible ideas, and as an approach to the study of the basic biology of the eucaryotic genetic system.

1977, 192 pp., \$9.50/£6.75 ISBN: 0-12-601150-8

LAKES OF NEW YORK STATE

VOLUME 1/THE FINGER LAKES REGION

Edited by JAY A. BLOOMFIELD

This volume on the present ecological condition of the Finger Lakes is the first of a unique series that will profile the physical, chemical, geological, and biological properties of freshwater lakes in New York State. Emphasis is placed on eutrophication, pollution, and other ecological factors changing the environment of these lakes. Much of the material is of a general nature and should be of interest to many ecologists working on temperate zone freshwater lakes. The volume documents existing knowledge, and represents a framework for future ecological studies and attempts at environment management.

1978, about 475 pp., in preparation ISBN: 0-12-107301-7

THE BIOLOGY AND CULTIVATION OF EDIBLE MUSHROOMS

Edited by S. T. CHANG

In this book, contributors from eleven countries give perhaps the first comprehensive account of the twelve most popular species of cultivated mushroom. The book represents an attempt to bridge the gap between researchers and growers, and is written to be read by both groups. It will show researchers the problems faced by growers, and will familiarize growers with some of the basic biological facts about the fungi they cultivate. The book discusses progress and problems in ascertaining nutritive value, increasing quality and yield of present species, discovering new species, improving media and techniques for growing mushrooms, and eventually increasing supply and lowering cost.

1978, about 750 pp., in preparation ISBN: 0-12-168050-9

* Subscription prices for individual volumes are valid only on orders for the complete set received before publication of the last volume. Subscription prices are not valid in the United Kingdom, Australia, and New Zealand.

Vibrational and Rotational Relaxation in Gases

J. D. Lambert

This concise survey of experimental data enables its readers to appreciate the quantitative effects of the physical factors involved. The topics include catalytic and anti-catalytic effects in energy transfer, the way in which energy transfer processes can lead to population inversions which give rise to laser or maser action, and the new information-theoretic approach to energy transfer in relation to the Lambert-Salter plot and other linear relationships. £8.75 *International Series of Monographs on Chemistry*

The Numerical Treatment of Integral Equations

Christopher T. H. Baker

There is a growing interest in the numerical solution of integral equations, and the author here provides a comprehensive account of modern knowledge of the subject by describing and illustrating available techniques, and investigating the theoretical background for the methods. £22.50 *Monographs on Numerical Analysis*

Quantitative and Numerical Methods in Soil Classification and Survey

R. Webster

Many numerical methods may be used in soil survey, some well-established, others relatively new. This book considers the methods available for survey and classification and the role of computers, and guides the reader in his choice of method and equipment. Practical problems are described, possible solutions mentioned, and the more appropriate ones discussed in detail. The emphasis throughout is on fully quantitative methods, measurement or careful estimation of soil properties of interest, and proper planning. £12.50 *Monographs on Soil Survey*

Boolean-Valued Models and Independence Proof in Set Theory

J. L. Bell

Since the discovery by P. J. Cohen in 1963 of the independence proofs for the Axiom of Choice and the Continuum Hypothesis, a vast amount of work has been done on the foundations of set theory. This book aims at a motivated account of some of the most important results. £5.95 *Oxford Logic Guides*

New Medicine Texts

Crohn's Disease

Bryan Brooke, David R. Cave, John F. Gurry and Denis W. King

An up-to-date review based mainly on the research and experimental work of the authors, indicating that Crohn's Disease is probably infective. The book seeks to provide a basis from which physicians and surgeons can build a pragmatic treatment. £9.75

Artificial Organs

Proceedings of a seminar on the clinical applications of membrane oxygenators and sorbent-based systems

Edited by R.M. Kenedi, J.M. Courtney, J.D.S. Gaylor and T. Gilchrist

Reproduces the forty-five papers presented at the conference, which discussed research, development and clinical applications in the area of membrane oxygenation and sorbent-based systems. The therapeutic role of the latter was explored in kidney and liver failure and drug overdose. £20.00

Introduction to Epidemiology

M.R. Alderson

An account of the various approaches that may be made in descriptive, analytical and intervention studies in the health field. The book is unique in the attention it pays to the use of routine mortality and morbidity data and in its discussion of medical care studies and the problem of data collection. £8.95/£4.50

Forthcoming titles:

Introduction to Cancer Medicine

Kenneth Calman and John Paul
1978, about £7.95/£3.95

Basic Principles of Cancer Chemotherapy

Kenneth Calman and M.N.H. Tattersall
1978, about £2.95, illustrated

To order a copy of any of these books, please send the correct amount, plus 50p per volume carriage, with your order to Technical Book Services, P.O. Box 79, Maidenhead, Berkshire SL6 2EG.

Coastal zone ecology

The Coastline. Edited by R. S. K. Barnes. Pp. 356. (Wiley: Sussex, New York and Sydney, 1977.) £12.50; \$24.50.

By a nice piece of timing, the publication date of this book coincided with the First European Ecological Symposium on Ecological Processes in Coastal Environments at Norwich, where it was exhibited by the publishers. It certainly caught the attention of the conference participants who seemed to like what they saw; so did I. Having now had the opportunity to read it in some detail, my opinion has not changed.

The stated purpose of the book is to contribute to our understanding of the coastline's ecology and physiography in relation to land-use, management and the pressures to which it is subject. To meet this objective, the editor has brought together a team of contributors who have done an admirable job in condensing a relatively large amount of information into one very readable volume. After an introductory chapter on problems and pressures, there follow thirteen chapters, each concerned with one fairly uniform group of habitats. Seven chapters describe predominantly aquatic environments (lagoons, estuaries and foreshores) and six cover terrestrial environments (reclaimed land, cliffs, dunes and shingle). A common structure has been adopted for each chapter: a summary of the ecological and geomorphological processes, characteristic features and pressures, recommendations for methods of study, particular uses, and finally suggestions for conservation and management policies. Coastline management is dealt with in more detail in a concluding chapter.

Many of the examples given are of British coastal areas, but others are from mainland Europe and some from as far afield as Australia. The diagrams which illustrate the various sections are generally good but the reproduction of the (fortunately few) photographs is very poor. There are errors, but those I found are mostly minor spelling mistakes. However, inaccuracies do occur: for example, on p144, it is erroneously stated that the Nature Conservancy Council do not own land. I consider that there are also some errors of omission. Current proposals for energy generation from a Severn Barrage or wave energy converters are not included; the effect of either on the coast would probably be considerable.

Although thermal pollution is mentioned, the possible damaging effects on plankton by its entrainment in cooling water systems is not discussed. The introduction of alien species, which has already led to a great many changes in some ecosystems, is dealt with rather superficially. It would have been valuable if some developing ideas about various ecosystems were included, such as the probable part played by diatoms and some invertebrates in stabilising sediments by their mucus secretions. It is surprising how little is said about ecological and conservation evaluation of coastal ecosystems, surely an essential step in formulating any management proposals. Perhaps more would have been included on this subject had *A Nature Conservation Review* (for review, see *Nature*, 269, 271, 1977) been published a few years earlier.

Atmospheric highlights

Earth's Aura. By Louise B. Young. Pp. 305. (Alfred A. Knopf: New York, 1977.) \$12.95.

This is a book about some of the highlights of the history of atmospheric exploration, about the effect of man's activities on the atmosphere and about the effect of climate on man. In the first chapter we are taken up with pioneering balloonists rising to unbelievable heights in flimsy baskets as the main structures of the various regions of the atmosphere are introduced. The second and third chapters introduce us to clouds and cloud-seeding experiments, and describe thunderstorms by recounting the drama of Franklin's classic kite experiment and the experience of a German glider pilot caught in a cumulonimbus. The delicate balances which control some of the atmosphere's chemistry (including the ozone problem) are introduced in the next three chapters. The enormous variety of winds, jet streams and waves come next; then optical phenomena, the solar wind and the atmospheres of the planets are dealt with in the same dramatic style. Modern speculations about the way the climate may change are discussed in a final chapter.

It is a fascinating account written in an enthusiastic, dramatic, sometimes gripping, style. The material has been effectively selected so that the book is not only very readable but also informative. Some beautiful colour pictures from space are included in the collection of ten illustrations in the centre of the volume.

Both the general reader and the

As stated in the concluding chapter, we still have to rely heavily on a descriptive approach to many ecosystems, as not enough is known to quantify them; we still have some way to go before we can be confident in our predictive capabilities as coastal managers. In relation to this, it would have been valuable to have had a discussion of the last chapter which concerned itself more fully with an appraisal of the state of the coastline. Nonetheless, I strongly recommend the book to those concerned with coastal management as well as to those seeking a lead into the study of this fascinating zone.

R. Mitchell

R. Mitchell is a Marine Biologist and the Chief Scientist's Team at the Nature Conservancy Council, Huntingdon.

specialist will be left with a new perspective on the environment and a new enthusiasm for the continued quest. "Weather is probably the most dominant factor in determining the quality of human existence", we are reminded, "but although we have set foot on the Moon, have identified organic molecules in the tenuous dust of outer space and measured the stars of galaxies a billion light years away, we still do not understand the intricate interplay of forces that make the earth's weather".

On the whole, the book does give the present state of knowledge in an accurate way. The emphasis is on two of the chapters, however, to leave the reader with a milder impression. One might have wished for instance that alongside the detailed description of the 1952 drought and the far-reaching changes brought about by the 1957 Clean Air Act, more had been described. Less attention is also given to the relatively small area of the influence of climate of sunspot cycles on the earth, whereas virtually no mention is made of the ocean/atmosphere interaction and feedback processes in the Arctic or Antarctic ice regions, the probably of much greater importance.

The cover describes this as a popular science writing at its best. It is a pleasure and discovery of the new problems that still face us. I have enjoyed reading it: it must be one of the best popular science books I have read deals with the atmosphere.

Further, for a well printed volume of 700 pages and some colour illustrations, the book is moderately priced.

J. T. Houghton

J. T. Houghton is Professor of Atmospheric Physics at the Clarendon Laboratory, Oxford, UK.

Churchill Livingstone

Evans' Histological Appearances of Tumours

David J. B. Ashley

A standard reference for both specialist tumour histopathologists and general histopathologists. The emphasis is on the relationship between histopathology of tumours and their clinical features.

1978. Third edition 900 pages 1466 illustrations £40.00

Theory and Practice of Histological Techniques

Edited by John D. Bancroft and Alan Stevens

Covers laboratory techniques from the principles of tissue fixation to scanning electron microscopy.

1977 436 pages fully illustrated + 8 pages of colour plates £13.00

EARTH'S FLIGHT BEYOND

LOUIS JACOT

This book sounds a word of warning!

The author considers that the great advances made in recent years in astronomy and physical science have been misunderstood, and that essential long-term conclusions to be drawn from those advances have been obscured by scientific obsession with outmoded theories.

The author's intention is not to spread alarm, but to bring the reader's attention, in sober terms, to things as they are and as they will be.

*A book that no-one who has the future
of the planet at heart can afford to ignore.*

Wild M40 – the simple, direct way.

Investigations in vitro.

Laboratory vessels, Erlenmeyer flasks, tissue culture chambers and Terasaki chambers are placed directly in the beam path of the Wild M40 inverted microscope. Liquids, sediments, precipitates, solution processes, crystal formation, culture growth and chemical reactions can therefore be readily observed.

The controls are conveniently low slung, and there is a six-place nose-piece. The base, the drive housing and the optics carrier form a single rigid unit which imparts the necessary stability to the instrument. The rich variety of interchangeable accessories enables the instrument to be expanded for cytology, bacteriology, immunology, environmental studies, chemistry etc. The information is in brochure M1 140e.

WILD
HEERBRUGG

Seed Pathology Volumes 1 and 2

Paul Neergaard

This is a unique and comprehensive compilation of the most recent data on the subject, brought together by an internationally recognised authority. It is the first book in this field and it is thoroughly up to date.

Paul Neergaard gives a comprehensive survey of research and current concepts relating to seed-borne diseases, the methods used for their identification and control, the mechanics of their transmission through seeds, procedures for laboratory seed testing, and the risk assessment of crop losses due to seed-borne diseases. The book will have a wide application both as a university textbook and as a practical guide and reference work for those involved in almost any sphere of the subject.

Contents

Volume 1 – Part I: Pathogens – Diseases – Hosts –
Economic Significance of Seed-Borne Diseases –
Diseases and Injuries of Seed – Seed-Borne Viruses –
Seed-Borne Bacteria – Seed-Borne Fungi – Seed-Borne
Nematodes – Storage Fungi – Impact of Seed-Borne and
Storage Fungi on Animal and Human Health – Types of
Host in Relation to Types of Pathogen – Morphology and
Anatomy of Seeds in Relation to Transmission of
Pathogens.

Part II: Mechanisms of Seed Transmission –
Introduction to Part II – Environment and Plant-Seed
Infection – Entry Points of Seed Infection – Infected or
Contaminated Parts of the Seed – Seed-Plant
Transmission, Establishment of Infection and Course of
Disease – Environmental Physicochemical Factors
Affecting Establishment and Course of Disease –
Environmental Biotic Factors Affecting Establishment
and Course of Disease – Intermezzo – Factors Inherent
in the Pathogen Affecting Establishment and Course of
Disease.

Volume 2 – Part III: Principles of Control –
Introduction to Part III – Seed Crop Management –
Management of Seed Storage – Seed Treatment,
Procedures and Equipment – Mechanism and Practical
Use of Chemical Seed Treatment – Testing Seed
Germicides and Treated Seed – Quarantine for Seed.

Part IV: Seed Health Testing Methods –
Objectives of Seed Health Tests – Sampling –
Examination of Ungerminated Seed – Incubation Tests
1: Procedures – Incubation Tests II: Factors Affecting
Test Results – Bioassays and Biochemical Procedures –
Inspection of Plants Beyond the Seedling Stage.

Part V: Assessment of Seed-Borne Inoculum –
Forecasting Losses from Seed-Borne Diseases and
Assessing Disease Tolerances for Seed Testing.

PRESS

Mathematics

- BAKER, Christopher T. H. *The Numerical Treatment of Integral Equations*. (Monographs on Numerical Analysis.) Pp.xiv + 1034. (Oxford: Clarendon Press; London: Oxford University Press, 1977.) £22.50.
- COLIN, Andrew J. T. *Programming and Problem-solving in Algol 68*. (Macmillan Computer Science Series.) Pp.viii + 251. ISBN-0-333-23115-5. (London and Basingstoke: The Macmillan Press, Ltd., 1978.) £4.50.
- DODSON, C. T. J., and POSTON, T. *Tensor Geometry: The Geometric Viewpoint and Its Uses*. (Surveys and Reference Works in Mathematics. 1.) Pp.xii + 598. ISBN-0-273-00317-8. (London, San Francisco and Melbourne: Pitman, 1977.) £19.
- FIORINI, S., and WILSON, R. J. *Edge-Colourings of Graphs*. (Research Notes in Mathematics. Vol. 16.) Pp.154. ISBN-0-273-01129-4. (London, San Francisco and Melbourne: Pitman, 1977.) £6.50.
- JOHNSTONE, P. T. *Topos Theory*. (London Mathematical Society Monographs No. 10.) Pp.xiii + 367. ISBN-0-12-387850-0. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1977.) £17.50; \$34.25.
- KNOPS, R. J. *Nonlinear Analysis and Mechanics: Heriot-Watt Symposium, Vol. 1*. (Research Notes in Mathematics. Vol. 17.) Pp.241. ISBN-0-273-01128-6. (London, San Francisco and Melbourne: Pitman, 1977.) £7.
- MILLER, John J. H. (edited by). *Topics in Numerical Analysis III*. (Proceedings of the Royal Irish Academy Conference on Numerical Analysis, 1976.) Pp.xiv + 477. ISBN-0-12-496953-4. (London and New York: Academic Press, 1977. Published for The Royal Irish Academy.) £23; \$44.90.
- PFEFFER, Washel F. *Integrals and Measures*. (Pure and Applied Mathematics: a Series of Monographs and Textbooks. Vol. 42.) Pp.ix + 259. ISBN-0-8247-6530-3. (New York and Basel: Marcel Dekker, Inc., 1977.) \$Fr.65.
- SHOWALTER, R. E. *Hilbert Space Methods for Partial Differential Equations*. (Monographs and Studies in Mathematics. Vol. 1.) Pp.xii + 196. ISBN-0-273-01012-3. (London, San Francisco and Melbourne: Pitman, 1977.) £14.
- WHEEDEN, Richard L., and ZYGUMUND, Antoni. *Measure and Integral: An Introduction to Real Analysis*. (Pure and Applied Mathematics: a Series of Monographs and Textbooks. Vol. 43.) Pp.x + 274. ISBN-0-8274-6499-4. (New York and Basel: Marcel Dekker, Inc., 1977.) \$Fr.54.

Astronomy

- ASIMOV, Isaac. *The Collapsing Universe: The Story of Black Holes*. Pp.204. ISBN-0-09-131770-3. (London: Hutchinson and Co. (Publishers), Ltd., 1977.) £4.50 net.
- BLUNCK, Jürgen. *Mars and Its Satellites: a Detailed Commentary on the Nomenclature*. Pp.200. ISBN-0-682-48676-0. (Hicksville, New York: Exposition Press, 900 So. Oyster Bay Road, 1977.) \$10.
- BOHME, S., ESSER, U., FRICKE, W., GUNTZEL-LINGNER, U., KRAHN, I., HEINRICH D., SCHMADEL, L. D., and ZECH, G. (edited by). *Astronomy and Astrophysics Abstracts*. (A Publication of the Astronomisches Rechen-Institut Heidelberg, Member of the Abstracting Board of the International Council of Scientific Unions. Vol. 19: Literature 1977, Part 1. Pp.x + 732. ISBN-3-540-08555-6. (Berlin and New York: Springer-Verlag, 1977. Published for Astronomisches Rechen-Institut.) DM95; \$43.70.
- EWERS, Ralph O., and EWERS, Lynda M. *A Universe to Explore: Searching for Structure*. Pp.iv + 92. ISBN-0-03-922123-7. (Toronto and Montreal: Holt, Rinehart and Winston of Canada, Ltd., 1976.) £3.50.
- LANDSBERG, Peter T., and EVANS, David A. *Mathematical Cosmology: an Introduction*. Pp.x + 309. ISBN-0-19-851136-1. (Oxford: Clarendon Press; London: Oxford University Press, 1977.) £6.95 net.
- MESSÉL, H., and BUTLER, S. T. (edited by). *Focus on the Stars*. Pp.287. ISBN-0-435-68282-2. (London: Heinemann Educational Books, Ltd., 1977.) £4.80 net.
- SHEA, M. A., SMART, D. F., and WU, S. T. (edited by). *Study of Travelling Interplanetary Phenomena, 1977*. (Proceedings of the L. D. de Feiter Memorial Symposium held in Tel Aviv, Israel, June 7-10, 1977.) (Astrophysics and Space Science Library, Vol. 71.) Pp.xii + 439. ISBN-90-277-0860-6. (Dordrecht, Holland and Boston, Mass.: D. Reidel Publishing Company, 1977.) Dfl. 95; \$38.
- THE INDISPENPHMERIS AND NAUTICAL ALMANACH for the year 1978. Pp.xxii + 469. (Delhi: Controller of Publications; London: The High Commission of India 1977.) Rs. 30; £3.50; \$10.80.
- WALD, Robert M. *Space, Time, and Gravity: The Theory of the Big Bang and Black Holes*. Pp.viii + 131. ISBN-0-226-87030-8. (Chicago and London: The University of Chicago Press, 1977.) \$10.95; £7.70.

Physics

- BRUSSAARD, P. J., and GLAUDEMANS, P. W. M. *Shell-Model Applications in Nuclear Spectroscopy*. Pp.xii + 452. ISBN-0-7204-0336-7. (Amsterdam, New York and Oxford: North-Holland Publishing Company, 1977.) Dfl. 160; \$65.50.
- BURNS, Gerald. *Introduction to Group Theory with Applications*. (Materials Science and Technology.) Pp.xv + 429. ISBN-0-12-145750-8. (New York and London: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1977.) \$18.50; £13.15.
- CLARKSON, B. L. (edited by). *In association with HAMMOND, J. K., HOLMES, P. J., and KISTNER, A. Stochastic Problems in Dynamics*. Pp.566. ISBN-0-273-01104-9. (London, San Francisco and Melbourne: Pitman, 1977.) £12.
- COOBLIN, B. *The Electronic Structure of Rare-Earth Metals and Alloys: The Magnetic Heavy Rare-Earths*. Pp.xvi + 656. ISBN-0-12-18815-4. (London and New York: Academic Press, a Subsidiary of Harcourt Brace Jovanovich, Publishers, 1977.) £29.50; \$57.75.
- HENDERSON, S. T. *Daylight and Its Spectrum*. Second edition. Pp.x + 349. ISBN-0-85274-343-2. (Bristol: Adam Hilger, Ltd., 1977.) £12.50 net.
- HOLAH, G. D. (edited by). *Ternary Compounds, 1977*. (Invited and contributed papers from the Third International Conference on Ternary Compounds held at Heriot-Watt University, Edinburgh, 14-15 April 1977.) (Conference Series No. 35.) Pp.ix + 326. ISBN-0-85498-126-8. (Bridgdon and London: The Institute of Physics, 1977. Published in association with the American Institute of Physics, New York.) £20; \$38.

- WEINSTEIN, Boris (edited by). *Chemistry and Biochemistry of Amino Acids, Peptides, and Proteins: a Survey of Recent Developments*, Vol. 4. Pp.xi + 339. ISBN-0-8247-6604-0. (New York and Basel: Marcel Dekker, Inc., 1977.) \$Fr. 128.

Technology

- ANGRIST, Stanley W. *Direct Energy Conversion*. Third edition. Pp.vii + 518. ISBN-0-205-05581-8. (Boston, Mass. and London: Allyn and Bacon, Inc., 1977.) £13.95.
- BLAKER, Alfred. *Handbook for Scientific Photography*. Pp.xxii + 319. ISBN-0-7167-0285-1. (San Francisco: W. H. Freeman and Company, 1977.) \$22.50.
- COLUCCI, Joseph M., and GALLOPOULOS, Nicholas E. (edited by). *Future Automotive Fuels: Prospects, Performance, Perspective*. Pp.ix + 380. ISBN-0-306-31017-1. (New York and London: Plenum Press, 1977.) \$47.40.
- ELECTRIC CIRCUITS: a First Course in Circuit Analysis for Electrical Engineers. By Members of the Staff of the Department of Electrical Engineering, MIT. (Principles of Electrical Engineering Series.) Pp.xxxiii + 782. (Cambridge, Mass.: The MIT Press, 1977.) \$6.95.
- FOSTER, Arthur R., and WRIGHTS, Jr., Robert L. *Basic Nuclear Engineering*. Third edition. Pp.xii + 548. ISBN-0-205-05697-0. (Boston, Mass. and London: Allyn and Bacon, Inc., 1977.) £9.75.
- HEARN, E. J. *Mechanics of Materials: An Introduction to the Mechanics of Elastic and Plastic Deformation of Solids and Structural Components*. Vol. 1: Pp.xxix + 1-394. ISBN-0-08-018749-8. £10. Vol. 2: Pp.xxii + 395-643. ISBN-0-08-020617-4. £7.50. (Pergamon International Library of Science, Technology, Engineering and Social Studies International Series in Materials Science and Technology, Vol. 19.) (Oxford and New York: Pergamon Press, 1977.)

what's new – centrifuges

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. More detailed information may be obtained by circling the appropriate numbers on the Reader Enquiry Card, bound inside the cover. A feature on balances will appear in the 8 May issue.

Damon/IEC. The IEC DPR-6000 high-capacity mid-speed refrigerated centrifuge features a digital speed readout that gives precision to 10 r.p.m., eliminating the need for periodic speed calibration. The DUR-6000 is fitted with a flexible drive shaft, a brush-wear indicator, durable range timer, variable electric brake and precise temperature control. The DPR-6000 attains a maximum speed of 6,000 r.p.m. and maximum force of 7,275g. Maximum capacity is 6 l. The IEC range also includes eight models of bench-top centrifuge and the B-20A and B-60 ultracentrifuges.

Circle No. 51 on Reader Enquiry Card.

The IEC Clini-cool refrigerated bench-top centrifuge

Gallenkamp. The Gallenkamp CFC-301 bench-top centrifuge has a maximum total capacity of 200 ml and has a top speed of 5,000 r.p.m. A built-in timer provides automatic control of running time for up to 20 min, if required. The self-balancing action of the motor ensures that centrifuge tubes need only be balanced by eye. Speed control is provided and choice of swing-out and angle heads is available. Centrifuge CFD-400 is suitable for a large number of routine and research applications, and has a maximum speed of 5,000 r.p.m. and total capacity up to 1,000 ml.

Circle No. 52 on Reader Enquiry Card.

DuPont Instruments (Sorvall). The GLC-3 bench-top model has a capacity of 80 tubes from 10×75- to 12×75-mm at speeds of up to 3,400 r.p.m. and forces of

1,240g. The GLC-2B also takes 80 tubes, providing speeds up to 2,600 r.p.m. and 1,240g. Higher g forces are attained by using buckets; the GLC-2B providing speeds up to 6,000 r.p.m. with fixed-angle rotors. The Sorvall RC-5B superspeed refrigerated centrifuge is equipped with a built-in automatic rate controller for soft starts and stops. Temperature, speed and time are programmed automatically. The rate of acceleration can be varied between start and 100 r.p.m. to give optimum acceleration for density gradient runs with vertical and zonal rotors. The Sorvall OTD-50 ultracentrifuge provides speeds up to 50,000 r.p.m. and forces up to 300,000g and the OTD-65 provides 65,000 r.p.m. and 429,297g. Both ultracentrifuges are self-contained: the self-contained cooling unit eliminates the need for external plumbing, filter and valves. The RC-5 superspeed and the OTD ultracentrifuges can be fitted with Sorvall vertical rotors which allow the rapid performance of density gradient separations.

Circle No. 53 on Reader Enquiry Card.

Beckman. The TJ-6 bench-top centrifuge is available with or without refrigeration. The TJ-6 provides speeds of up to 2,700 r.p.m. and 1,520g. Fixed-angle rotors (10×50 ml and 24×15 ml) are rated for 5,700 r.p.m. and 4,470g. The Microfuge B miniature centrifuge holds 48 250- or 400-μl tubes or 18 1.5 ml tapered-bottom tubes. It accelerates almost instantaneously to top speed and can spin down blood cells or protein precipitates in 1 min. Separations for RIA take 3 min. The Model J-21C floor-model centrifuge is designed as a general laboratory centrifuge for initial processing of large particles in large volumes at up to 21,000 r.p.m. and 50,330g. The Beckman range of preparative ultracentrifuges includes the Model L5-40, with a maximum speed of 40,000 r.p.m., 284,000g and the L5-75 which can operate at 75,000 r.p.m., 504,000g. The Beckman Airfuge is a miniature table-top ultracentrifuge capable of rapidly separating small volumes. The rotor holds six 175-μl samples and attains 100,000 r.p.m., 160,000g in 30 s. The Airfuge is powered by standard laboratory air pressure.

Circle No. 54 on Reader Enquiry Card.

MSE Scientific Instruments. The MSE Prepspin 50 preparative ultracentrifuge operates at up to 50,000 r.p.m.

(347,000g) with a maximum capacity of 2,000 ml. The Prepspin features a new overspeed protection system, a wide range of angle and swing-out rotors in aluminium and titanium, full zonal capability, variable acceleration and braking, fast acceleration, automatic oil recirculation, and a brush-wear indicator. Also available are the Prepspin 65 and Prepspin 75 for operation at higher

MSE Prepspin 75

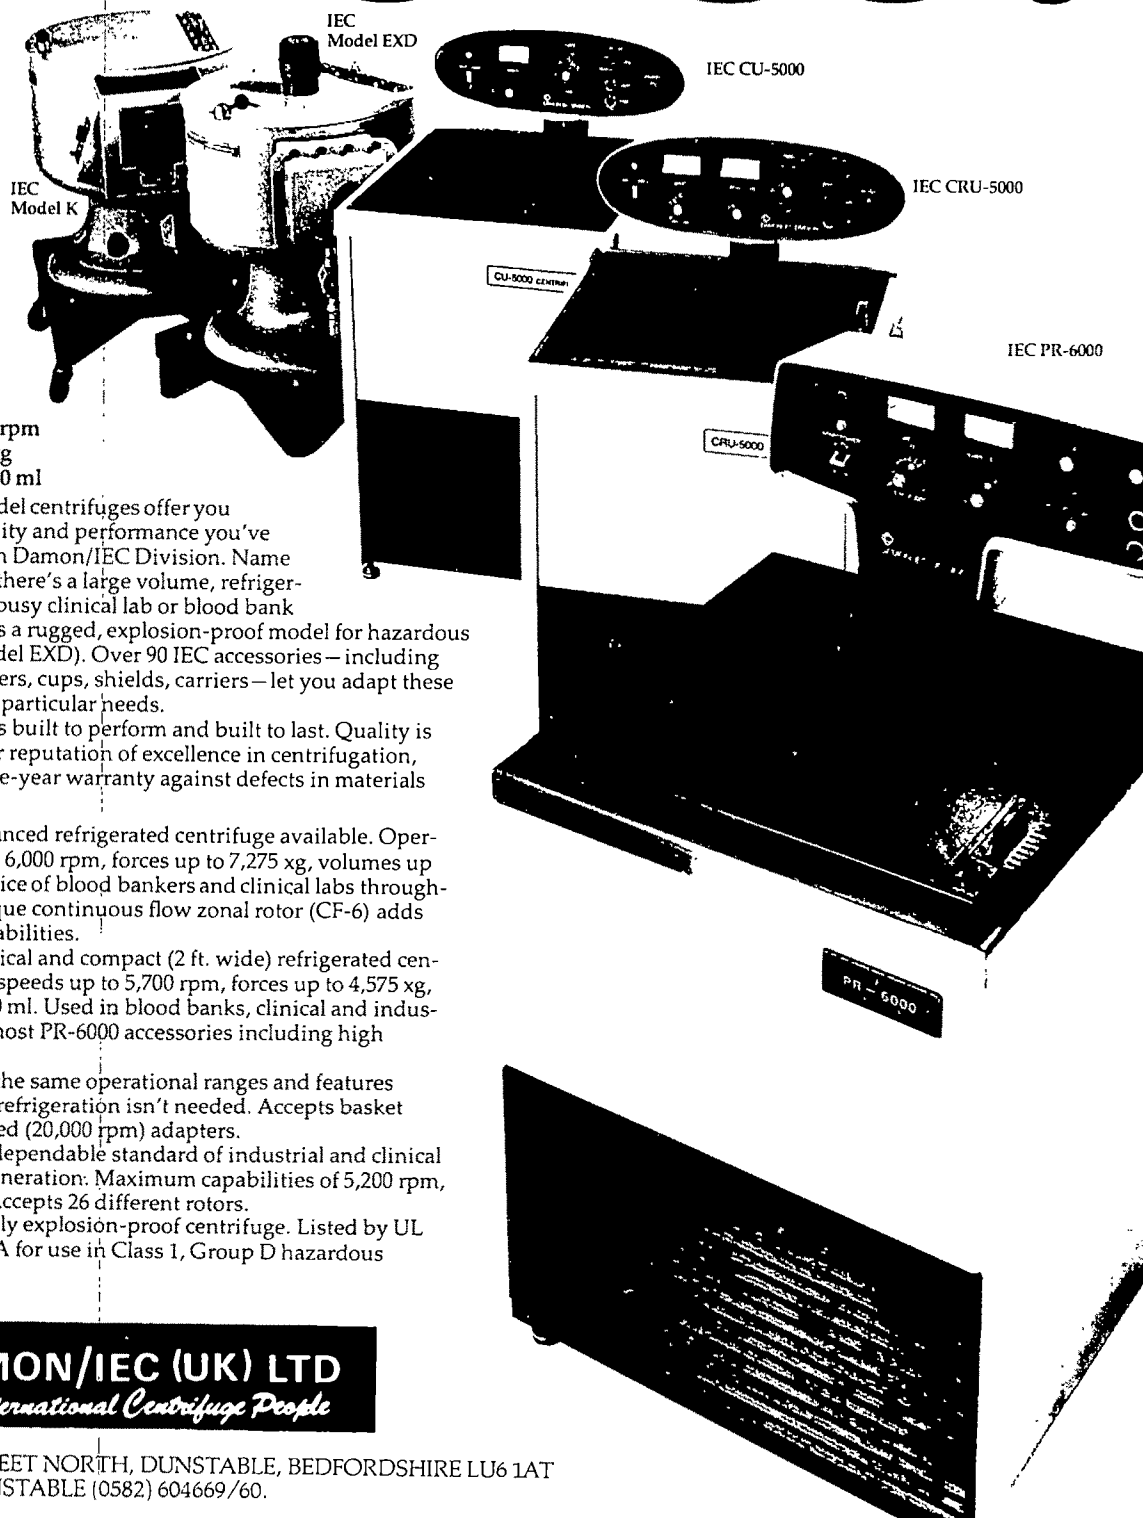

speeds. The Coolspin is a refrigerated centrifuge particularly suited for use in blood transfusion centres. The capacity of this centrifuge is 6 l at over 5,000g; it can accommodate 12 blood bags or carry 288 samples at one time. The Coolspin operates in the temperature range -20° to -40°C: acceleration and braking are variable and acceleration is fast. The range of rotors includes a 4×1,000 ml windshielded swing-out rotor developing 6,140g at 5,200 r.p.m., a two-place head for use in radio-immunoassay and autoanalyser work and the 'A' type zonal rotor. The Hi-Spin 21 is a high-speed 3-l capacity refrigerated centrifuge. The rotor complement includes large-capacity angle rotors such as the 6×500 ml and the 24×15 ml rotors, a continuous action rotor and the HS zonal rotor. To meet the demand for a simple and reliable refrigerated bench-top centrifuge MSE have produced the Chilspin. Chilspin has a maximum speed of 6,100 r.p.m. (6,030g) and uses the same rotors and accessories as the MSE Super Minor.

Circle No. 55 on Reader Enquiry Card.

Hettich. The Hettich EBA 3S is a newly designed bench-top laboratory centrifuge. The spin time can be set to 1-60 min, and the speed of rotation can be pre-selected and monitored on a revolution counter. Angular steel rotors are provided for either four or six buckets. Balancing is not essential because of the elastic suspension of the drive in the housing. The maximum rotor speed is 5,500 r.p.m.

Circle No. 56 on Reader Enquiry Card.

Choice.

Speeds up to 6,000 rpm
Forces up to 7,275 xg
Volumes up to 6,000 ml

These five floor model centrifuges offer you the versatility, quality and performance you've come to expect from Damon/IEC Division. Name your application—there's a large volume, refrigerated model for the busy clinical lab or blood bank (PR-6000), as well as a rugged, explosion-proof model for hazardous environments (Model EXD). Over 90 IEC accessories—including rotors, rings, adapters, cups, shields, carriers—let you adapt these centrifuges to your particular needs.

Each centrifuge is built to perform and built to last. Quality is backed by a 75-year reputation of excellence in centrifugation, along with a full one-year warranty against defects in materials or workmanship.

PR-6000. Most advanced refrigerated centrifuge available. Operates at speeds up to 6,000 rpm, forces up to 7,275 xg, volumes up to 6,000 ml. The choice of blood bankers and clinical labs throughout the world. Unique continuous flow zonal rotor (CF-6) adds ultracentrifuge capabilities.

CRU-5000. Economical and compact (2 ft. wide) refrigerated centrifuge. Capable of speeds up to 5,700 rpm, forces up to 4,575 xg, volumes up to 4,000 ml. Used in blood banks, clinical and industrial labs. Accepts most PR-6000 accessories including high speed adapters.

CU-5000. Provides the same operational ranges and features as CRU-5000 when refrigeration isn't needed. Accepts basket rotors and high speed (20,000 rpm) adapters.

Model K. Rugged, dependable standard of industrial and clinical laboratories for a generation. Maximum capabilities of 5,200 rpm, 4,275 xg, 6,000 ml. Accepts 26 different rotors.

Model EXD. The only explosion-proof centrifuge. Listed by UL and certified by CSA for use in Class 1, Group D hazardous environments.

FREELANCE TRANSLATOR (Ph.D.) Math. and Phys. Science and Technology from Russian, Ukrainian, Romanian and German. Rate Negotiable. Box 1391, Nature, Advertising Dept., c/o Macmillan Journals Ltd., 4 Little Essex Street, London WC2R 3LF. 1391(B)

APPOINTMENTS VACANT

UNIVERSITY OF GLASGOW RESEARCH TECHNICIAN

A research technician with extensive laboratory experience and some training in immunological techniques is required to assist in a study of the immunoregulation of IgE production. The post, which is funded by the M.R.C., is available for 1 year in the first instance on Grade 3 of the University technicians salary scale (starting salary: £2,688).

Applications and enquiries to Dr E. Jarrett, Dept., Vet., Path., the University Veterinary Hospital, Bearsden, Glasgow G61 1QH (041-942 2301, Ext. 54).

In reply please quote Ref. No. 4083M. 1454(A)

UNIVERSITY OF TORONTO. Department of Mathematics. Tenure-stream appointments at the rank of **ASSISTANT PROFESSOR, in MATHEMATICS, APPLIED MATHEMATICS or HISTORY OF MATHEMATICS.** Appointments to commence July 1, 1978 subject to budgetary approval. Ph.D. and evidence of excellence in teaching and research required. Application should be made as soon as possible to: The Chairman, Department of Mathematics, University of Toronto, Toronto, Canada, M5S 1A1. 1445(A)

MEDICAL RESEARCH COUNCIL LABORATORY OF MOLECULAR BIOLOGY RESEARCH ASSISTANT

required to join a group working on chemical aspects of protein and oligonucleotide synthesis. Candidates should possess or expect to obtain a degree, H.N.C. or equivalent qualification in a science subject.

Salary on scale according to experience, starting from £2,823 plus 5% supplement. Good prospects for permanency and promotion to research officer grade.

Applications giving details of qualifications, experience, and the names of two referees, should be sent to:

Dr R. C. Sheppard, M.R.C. Laboratory of Molecular Biology, The Medical School, Hills Road, Cambridge CB2 2QH, as soon as possible. 1420(A)

LEUKAEMIA RESEARCH UNIT

(Department of Haematology)

RESEARCH TECHNICIAN

Graduate in Biological Sciences required to work in Cytogenetics Laboratory of a unit providing both diagnostic and research facilities for the study of chromosome abnormalities in Leukaemia.

The successful candidate will be responsible for running the cytogenetics laboratory and will also have the opportunity to participate in the various ongoing research projects of the department.

Some experience in cytogenetics preferred but full training will be given. Salary on Whitley Councils' Scale.

For further details, contact Dr J. C. Sharp or Mr A. W. Wayne 01-274 6222 extension 2013. Written applications, giving full curriculum vitae and the names and addresses of two referees to the Secretary of the Medical School at the above address.

Closing date March 3, 1978.

1466(A)

UNIVERSITY OF SASKATCHEWAN COLLEGE OF DENTISTRY SASKATOON, CANADA ORAL BIOLOGY

Applications are invited for two full-time positions in the Department of Oral Biology. Depending on qualifications, applicants may be considered for Chairmanship of the Department.

ORAL PATHOLOGY: The applicant should have a dental degree and graduate training in Pathology—Oral and/or General. Responsibilities will include teaching at the undergraduate level, research and managing a diagnostic biopsy service.

ORAL BIOCHEMISTRY/ MICROBIOLOGY: The applicant should have a dental degree and graduate training preferably beyond the Masters level. Responsibilities will include teaching at the undergraduate level and research in biochemistry/microbiology.

Rank and salary will be determined according to qualifications and experience.

Letters of application and curriculum vitae should be sent to:

Dr E. R. Ambrose, Dean,
College of Dentistry,
University of Saskatchewan,
Saskatoon, Saskatchewan,
Canada S7N 0W0 1442(A)

UNIVERSITY OF TORONTO, Department of Mathematics. Possible tenure-stream and/or contractually limited positions at the rank of **ASSISTANT PROFESSOR in STATISTICS,** on the St George and/or Erindale College campuses. Appointments to commence July 1, 1978. Ph.D. and evidence of excellence in teaching and research required. Application should be made as soon as possible to: The Chairman, Department of Mathematics, University of Toronto, Toronto, Canada, M5S 1A1. 1447(A)

HERIOT-WATT UNIVERSITY EDINBURGH

Department of Physics

Applications are invited for the following positions, which will be associated with an established group in the area of **SOLAR ENERGY CONVERSION** by Photovoltaic Cells based on amorphous semi-conductors fabricated by the glow discharge process. The work of the group is funded by S.R.C. and the E.E.C.

POST-DOCTORAL RESEARCH ASSOCIATE

Applicants should have relevant research experience in experimental Solid State Physics, materials science, or electronic device technology. The position will be tenable for two years in the first instance. Salary on Research Range 1A (£3,333 to £5,627, under review).

RESEARCH TECHNICIAN

Applicants should preferably have experience as a research technician and mechanical and/or electronic workshop experience. Duties will include assistance with preparation and testing of solar cells. Grade of appointment is flexible. The probable salary range is £2,688 to £3,720.

RESEARCH STUDENTSHIP

A Research Studentship is also offered in the above area. Informal enquiries may be made to:

Dr J. I. B. Wilson,
Department of Physics,
Heriot-Watt University,
Telephone: 031-449 5111, Ext. 2388

Application forms are available from the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX. 1393(A)

FLOUR MILLING AND BAKING RESEARCH ASSOCIATION CHEMISTS AND BIOCHEMISTS STATISTICIAN/MATHEMATICIAN

The Flour Milling and Baking Research Association carries out a wide range of research and service work for the Milling and Baking Industries and holds a number of research contracts for the Ministry of Agriculture, Fisheries and Food. The laboratories are situated in an attractive semi-rural area on the edge of the Chilterns with ready access to London.

Several positions are available for graduates with strong research backgrounds who would be interested in carrying out basic and applied research on cereal problems.

PROTEIN CHEMIST/BIOCHEMIST

fundamental studies on cereal proteins

ORGANIC CHEMIST/BIOCHEMIST (two posts)

natural product chemistry

CHEMIST/ANALYTICAL CHEMIST

application of modern chemical/physical analytical techniques

BIOCHEMIST

nutritional and toxicological studies

STATISTICIAN/MATHEMATICIAN

statistical and mathematical service for the

Research Association

Applicants should have a Ph.D. degree and further research experience. For the post of Statistician/Mathematician a B.Sc. or equivalent or postgraduate qualification in statistics or mathematics together with several years applied experience is required.

Starting salary will depend on qualifications and experience within the Senior Scientific Officer (c. £4,350 to £5,810 p.a.) or Principal Scientific Officer (c. £5,620 to £7,120 p.a.) scales. There is a pension scheme and assistance with relocation expenses will be given where appropriate.

Further details can be obtained from Professor Brian Spencer, Director-General, Flour Milling and Baking Research Association, Chorleywood, Herts. WD3 5SH. Telephone: 092 78-4111. Applications, with the names and addresses of three referees, should be submitted by March 20. 1404(A)

Commercially Oriented Scientist

Foods Research

c. £8,000

This is an opportunity for a young scientist — probably mid-late twenties — to make his or her mark within an R & D team which has an impressive record of innovation and successful implementation in a competitive sector of the consumer food market.

The job will appeal to commercially minded scientists capable of relating their specialist skills to the broader business implications of food research. The objective of the R & D team is to maintain a fundamental research programme into new raw materials, products and food technologies. There is considerable scope for you to develop your original ideas within the team — provided you have the communicative powers to present and "sell" them to technical and commercial

management.

You will have a good honours degree or PhD in Food Technology or Science, Biochemistry or Biochemical Engineering backed by formal training in research and preferably practical experience in the food industry.

Starting salary will be around £8,000 plus full large company benefits including assistance with relocation to an attractive part of the rural East Midlands.

Ref: W4869/N

REPLIES will be forwarded direct, unopened and in confidence to the client unless addressed to our Security Manager listing companies to which they may not be sent. They should include comprehensive career details, not refer to previous correspondence with PA and quote the reference on the envelope.

A member of PA International

MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE Carshalton, Surrey

Applications are invited for the post of Senior Research Officer in the Director's Department.

The successful candidate will be expected to assist the Director with:

- (i) personal assistance with his administrative duties
- (ii) a research programme designed to evaluate specific pathogen free cats.

It is hoped that he/she will be a mature person with an interest in scientific administration. Applicants should have a degree in biological science, together with a Ph.D., and previous experience with small animals would be an advantage although not essential. The post offers excellent conditions of service. Salary in the range £3,999 to £5,199 according to age, qualifications and experience, plus £354 London Weighting, plus £312 Pay Supplement, plus Variable Pay Supplement. Contributory Superannuation Scheme.

Applications, together with a curriculum vitae and the names of two referees should be sent to the Director, Medical Research Council Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

1377(A)

MRC

Medical Research Council

UNIVERSITY OF SURREY SCIENTISTS FOR MANAGEMENT/PRODUCT DEVELOPMENT

Applications are invited for the position of Research Officer or Research Fellow to work on a Department of Industry sponsored project for two years duration concerned with the development of novel printing inks designed to facilitate the recycling of waste papers.

Candidates (male or female) should possess a high but versatile level of practical skills together with a multi-disciplinary approach to problem solving, preferably with a background in chemistry, polymer science or paper technology. Applicants should, in addition, have management potential and be capable of developing contracts with government agency and private industry to further the interests of the project.

Salary according to age, experience, etc. will be on either the Research Range 1B: £2,904 to £4,190 p.a. or Range 1A: £3,333 to £5,423 p.a. (under review).

Applications should be sent as soon as possible to:-

Dr M. L. Burstall,
Department of Chemistry,
University of Surrey,
Guildford,
Surrey, GU2 5XH.

1437(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the following posts: DEPARTMENT OF VETERINARY CLINICAL STUDIES —PROFESSOR. Applicants should be in possession of a recognised Veterinary degree with a higher degree or its equivalent in one of the following areas: Veterinary Medicine, Surgery, Reproduction and Obstetrics or Veterinary Preventive Medicine. Candidates must also have considerable teaching and research experience at the University level. A knowledge of Tropical Veterinary Medicine will be an added advantage.

DEPARTMENT OF VETERINARY PATHOLOGY AND MICROBIOLOGY—SENIOR LECTURER. Applicants must be veterinarians and have a Ph.D. in Pathology or Microbiology and must have teaching experience in undergraduate and graduate levels in Veterinary Medicine especially in infectious diseases of domestic and wild animals. Salary scales: Professor K£4,632 to K£5,562 p.a. Senior Lecturer K£2,988 to K£3,984 p.a. (K£1=£1.30). The British Government may supplement salaries in range £4,128 to £4,674 p.a. (sterling) for married appointees and £2,880 to £3,384 p.a. (sterling) for single appointees (reviewed, annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Terms of service include superannuation scheme, medical aid scheme, family passages and various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar, University of Nairobi, PO Box 30197, Nairobi, Kenya by March 7, 1978. Applicants resident in UK should send one copy to Inter-University Council, 90/91 Tottenham Court Road, London. W1P 0DT. Further details may be obtained from either address. 1433(A)

UNIVERSITY OF LONDON KING'S COLLEGE DEPARTMENT OF BIOCHEMISTRY

A full-time research position, financed by the Medical Research Council, is available for three years. The work will be concerned with the metabolism of messenger RNA during erythroid cell development.

Applicants should hold a Ph.D. degree, preferably in Biochemistry, and have previous experience of techniques relevant to nucleic acid isolation and cell-free protein biosynthesis.

Starting salary up to £3,569 per annum plus £450 per annum London Allowance plus provision for superannuation.

Applications, with full curriculum vitae and the names of two referees, should be sent as soon as possible to Professor H. R. V. Arnstein, Department of Biochemistry, King's College, The Strand, LONDON WC2R 2LS, from whom further information may be obtained, quoting reference 191603/N. 1465(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF MOLECULAR BIOLOGY

Applications are invited for an M.R.C. postdoctoral fellowship to work on the molecular relationships of plasmids, principally those carried by enterobacteria and *Pseudomonas* species from soil and clinical sources. A variety of biochemical and genetical techniques will be involved. These will include DNA-DNA hybridisation and probably heteroduplex analysis and the generation of recombinant plasmids both *in vivo* and *in vitro*. The appointment is for three years from April 1978 or when convenient thereafter. The starting salary will be between £3,333 and £4,190 p.a. as appropriate.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Dr P. M. A. Broda, Department of Molecular Biology, King's Buildings, Mayfield Road, Edinburgh, EH9 3JR. Please quote Reference 5001. 1436(A)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PATHOLOGY

Applications are invited for the following posts available from October 1, 1978:

LECTURER/ SENIOR LECTURER (ref. 102/2/D)

Applications are invited from registered medical practitioners. Duties will include teaching, research and health service work. A special interest in one of the main branches of histopathology, such as cardiac, respiratory, skeletal, dermatological, or oncology is desirable but not essential. The successful applicant will be appointed at the level most appropriate to experience and qualifications, and the AHA(T) will be asked to award honorary consultant status or other appropriate grade to a suitably qualified individual.

Salary on the scale for Honorary Consultants £7,536 (plus supplements of £312 and £208) to £8,327 (plus supplements of £178 and £208) to £9,111 (plus supplement of £208) to £9,900 (plus supplement of £208) to £10,689 (plus supplement of £208), or on the scale for Senior Clinical Lecturers £6,915 to £8,142 (plus supplement of £312) (under review), or on the scale for Clinical Lecturers £3,742 to £7,440 (plus supplement of £312) (under review).

The Department may be visited by arrangement with Professor C. C. Bird.

LECTURER (ref. 102/3/D)

Applications are invited from medical practitioners. Previous postgraduate experience in histopathology is desirable but not essential. Duties will include teaching, research and health service work. The AHA(T) will be asked to award a suitable honorary clinical contract.

Salary on the scale for Clinical Lecturers £3,742 to £7,440 (plus £312 supplement) (under review).

Application forms and further particulars for both posts may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting appropriate reference number. Closing date for applications March 10, 1978. 1399(A)

Young qualified **TECHNICIAN** required in new dermatology research laboratory in Clinical Science Laboratories, Guy's Tower, for investigative work in histopathology, histochemistry and electron microscopy. Experience in preparative techniques in electron microscopy and use of the transmission electron microscope essential; training in pathology an advantage. Appointment for one year in first instance from April 1, 1978. Initial salary in range £2,982 to £3,379 according to qualifications and experience, plus £354 London Weighting and superannuation. Applications with names of two referees to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. D.R.1. 1435(A)3

KINGSTON POLYTECHNIC

Appointment of PRINCIPAL LECTURER in GEOLOGY

The School operates a range of C.N.A.A. degree courses and is actively engaged in research. A good background of research is desirable, whilst industrial and/or survey experience would be an advantage.

Salary range including 1976 and 1977 supplements £6,432 to £7,134 (bar) to £8,070 plus £297 London allowance.

Further details and application forms (to be returned by March 6) from Academic Registry, Dept. AO, Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. 01-549 1366. 1449(A)

IMPORTANT INTERNATIONAL PHARMACEUTICAL GROUP

located in PARIS is presently offering an **EXCELLENT CAREER OPPORTUNITY** for a

BIOCHEMIST/PHARMACOLOGIST

to join in the **DEPARTMENT OF BIOLOGICAL RESEARCH THE METABOLIC AND ENDOCRINE DISEASE UNIT** as

PROJECT LEADER

for:

- the **DISCOVERY** and **EVALUATION** OF NEW DRUGS
- the **DRAFTING** AND **IMPLEMENTATION** OF NEW PRODUCTS IN **BASIC RESEARCH**.

Preference will be given to individuals with the following qualifications:

- Ph.D. degree
- postdoctoral or industrial research experience (3-5 years)
- good attitude towards team work
- age between 30 and 40 years.

An excellent salary and comprehensive benefit programme accompany this position.

RESEARCH SCIENTISTS — MARINE MAMMALOGISTS (2 positions)

Initial salary up to \$36,760 (dependent on experience)
Ref. No: 77-PSTP-32-155 (N)

Fisheries and Environment Canada
St. John's, Newfoundland

Duties

Two research scientists are required in the Marine Fisheries Management Program to conduct independent research into the biology, ecology and population dynamics of marine mammals in the North-West Atlantic area. One position involves work on the harp and hood seals and the other involves the cetacean species. The selected scientists will organize and participate in field surveys for the collection of data and specimens for investigations; and will analyse data, interpret variables and present results to the scientific community and resource managers in order that the latter may formulate policies for the rational use of each species.

Qualifications

Applicants must possess a Ph.D. or a lesser degree with evidence of research experience and productivity equivalent to that of the Ph.D. in the field of biology. Experience in the fields of marine mammalogy and population biology is also required. Knowledge of English is essential.

How to Apply

Send application form and/or résumé to:

Professional, Scientific and Technical Program
Public Service Commission of Canada

Ottawa, Ontario K1A 0M7

Closing Date: March 20, 1978

1406(A)

Please quote the applicable reference number at all times.

nature

Nature is considering employing a physical scientist to assist Dr Stuart Sharrock, the Physical Sciences Editor. Such a person would have recently received a Ph.D. and would be hoping to develop a much broader appreciation of science. He or she would be expected to help Dr Sharrock in the assessment of manuscripts, work with other members of the *Nature* staff in compiling the various sections of the journal, establish contacts in the scientific community and, on occasions, write short pieces on recent scientific developments.

Write to Editor, *Nature*, 4 Little Essex Street, London WC2 enclosing a c.v. and any other material you consider relevant.

1430(A)

UNIVERSITY OF THE WEST INDIES JAMAICA

Applications are invited for the following posts: PROFESSOR/SENIOR LECTURER IN APPLIED MATHEMATICS. The appointee will be a person specialising in Modern Applied Mathematics with teaching and research experience in Operational Research or Statistics or Control Theory and allied fields.

SENIOR LECTURER/LECTURER IN APPLIED MATHEMATICS. The appointee will be a person with teaching and research experience in Statistics or allied fields.

LECTURER / ASSISTANT LECTURER IN PHYSICAL CHEMISTRY. Applicants should have interests in either Photochemistry, Electrochemistry, Radiochemistry or Gas Phase Kinetics. Salary scales: Professor: 1977/78—J\$17,166 to J\$21,252 p.a. Senior Lecturer: 1977/78—J\$12,066 to J\$15,897 p.a. Lecturer: 1977/78—J\$8,913 to J\$ 13,917 p.a. Assistant Lecturer: 1977/78—J\$7,236 to J\$8,412 p.a. (£1 sterling=J\$2.42). F.S.S.U. Study and Travel Grant. Unfurnished accommodation will be let by the University at a rental of 10 per cent of salary, or a housing allowance of 20 per cent of salary will be paid. Family passages. Detailed applications (two copies) with curriculum vitae and naming three referees should be sent as soon as possible to the Registrar, UWI, Mona, Kingston, Jamaica. Further particulars are available from the same source or from the Inter-University Council for Higher Education Overseas, 90/91 Tottenham Court Road, London W1P 0DT. 1434(A)

UNIVERSITY COLLEGE DUBLIN

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for an academic post at the level of either Assistant Lecturer or College Lecturer in Biochemistry. Applications would be particularly welcomed from candidates with experience in any of the following fields—proteins, nucleic acids, immunochemistry. The appointment will be tenable from October 1, 1978.

The current salary scales are:

Assistant Lecturer: £3,661 to £6,081

College Lecturer: £5,840 to £7,544

Entry point on the relevant scale will be in accordance with qualifications and experience. Family allowances or equivalent will be paid in addition to the above scale.

There is a non-contributory pension scheme. An alternative contributory F.S.S.U. type scheme is also available. Prior to application, further information (including details of application procedure) should be obtained from Mr J. P. MacHale, Secretary and Bursar, University College, Belfield, Dublin 4. Telephone: 693244, Ext. 431.

The latest date for receipt of completed applications is Thursday, March 16, 1978. 1409(A)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY EXPERIMENTAL OFFICER IN NUTRITION

There is a vacancy for an Experimental Officer to work with the Professor of Human Nutrition, Professor J. W. T. Dickerson. Candidates should have a good honours degree in a relevant subject and preferably some postgraduate experience. A strong interest in nutritional research is essential.

Salary will be within the Experimental Officer range: £3,975 to £5,015 per annum, depending on age and

Further particulars and application forms may be obtained from the Assistant Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH, or telephone Guildford 71281. Ext. 452. Completed forms should be returned by March 2, 1978. 1401(A)

THE SCHOOL OF PHARMACY UNIVERSITY OF LONDON LABORATORY SUPERINTENDENT

LABORATORY SUPERINTENDENT (Grade 8) required as soon as possible to be responsible to the Professor and Head of Department of Pharmaceutics for the organisation of laboratory services for teaching and research and the supervision of 22 technical and ancillary staff. The successful applicant should have experience in financial planning and stock control.

The Department comprises Physical Pharmacy, Microbiology and Pharmaceutical Engineering Science. Applicants should possess H.N.C. or equivalent qualification, and have 10-15 years experience in similar or related laboratories. Experience in workshop and personnel administration would be advantageous.

Salary Scale £4,594 to £4,987 plus London Weighting £465 per annum.

Applications in writing, giving full details of experience, qualifications and names of two referees to:

The Personnel Officer, The School of Pharmacy, 29/39 Bunswick Square, London WC1N 1AX. 1469(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHARMACOLOGY

Applications are invited for an office of:

UNIVERSITY LECTURER IN THE DEPARTMENT OF PHARMACOLOGY

The initial appointment will be for three years from October 1, 1978, with the possibility of re-appointment to the retiring age.

The pensionable stipend for a University Lecturer is on scale £4,607 to £7,087 a year, with initial placing above the minimum where appropriate. There is no grade of Senior Lecturer. A grant is made towards removal expenses.

Candidates should send twelve copies of their application together with the names of not more than three referees to Mr G. R. Anderson, General Board Office, The Old Schools, Cambridge CB2 1TT, from whom further particulars can be obtained, to arrive not later than March 20, 1978. 1417(A)

AVON AREA HEALTH AUTHORITY (T)— SOUTHMEAD HEALTH DISTRICT

DEPARTMENT OF CLINICAL CHEMISTRY

SOUTHMEAD HOSPITAL, BRISTOL

Applications are invited for a training post as a Basic Grade Biochemist, in connection with the University of Surrey M.Sc. Course in Clinical Biochemistry. Suitable candidates would hold, or would be expecting to obtain, a 1st or 2nd Class Honours degree in an appropriate science.

The appointment is for 3 years, the first 2 of which are spent on the M.Sc. Course, attending at Guildford for alternate University terms. The salary would be within the Whitley Council scales and the trainee is responsible for paying the University Course fees.

Further details may be obtained from Dr D. J. Goldie or Dr J. B. Holton at the above address (or Bristol (0272) 622821) and application forms are available from the District Personnel Officer, Southmead Hospital, Westbury-on-Trym, Bristol BS10 5NB (Tel: Bristol (0272) 622821 Ext. 162).

Closing date for applications: March 4, 1978. 1413(A)

UNIVERSITY OF WARWICK
POSTDOCTORAL
RESEARCH FELLOW
in VIROLOGY

Applications are invited for a Post-doctoral Fellowship with the Virus Research Group in the Department of Biological Sciences. This post is concerned with the use of isolated nuclei to study molecular events occurring during influenza virus multiplication. Experience in virology, cell biology and techniques for analysing proteins and RNA would be an advantage. Initial salary will be on the Research Range 1A scale £3,333 to £5,627 per annum (under review). The Fellowship is funded by the Cancer Research Campaign and is available immediately; it is then renewable on an annual basis until September 1980. Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL, quoting Ref. No. 27/R/78. Closing date for receipt of applications March 10, 1978. 1408(A)

UNIVERSITY OF
EAST ANGLIA
SENIOR
RESEARCH ASSOCIATE

required for two years to work with Dr G. S. Boulton, School of Environmental Sciences and Dr L. W. Morland, School of Mathematics and Physics in an investigation of the interactions between glaciers and underlying deformable materials. Applicants should have a good grounding in theoretical mechanics or soil mechanics theory and preferably some experience in numerical methods. There would also be the possibility of field work for an interested person. Applicants should have completed a Ph.D. in mathematics or other related disciplines. The appointment would be made at the appropriate age-point within the salary range £3,333 to £5,219 p.a. (under review). Applicants should send a curriculum vitae and the names of two referees to Dr G. S. Boulton, School of Environmental Sciences, University Plain, Norwich NR4 7TJ. No forms of application are issued. 1450(A)

UNIVERSITY OF
GLASGOW
LECTURESHIP IN
GEOLOGY

Applications are invited for a lectureship in structural geology. Preference will be given to those combining field and theoretical studies. Interest in teaching Engineering geology or ore geology would be an advantage. The initial salary will be within the range £3,333 to £4,811 per annum on the Lecturers' scale of £3,333 to £6,655 per annum according to qualifications and experience. Appropriate Superannuation Scheme will apply.

Further particulars may be had from the Secretary of the University Court (Room 18). The University of Glasgow, Glasgow G12 8QQ, with whom applications (8 copies) giving the names and addresses of three referees, should be lodged on or before March 20, 1978.

In reply please quote Ref. No. 4081M. 1414(A)

GRADUATE ASSISTANT

A position is available to work in a group on metabolic aspects of connective tissue diseases. The candidate must have a good background in biochemistry, but experience is not essential.

The starting salary is up to £3,333 per annum, and carries U.S.S. benefits. The position is available for three years. Please send curriculum vitae and names of two referees to The Secretary, Srageways Research Laboratory, Wort's Causeway, Cambridge; 1403(A)

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

Agricultural Statistician

Lesotho

To collect, process, analyse and publish agricultural statistics and design agricultural surveys. Applicants should be qualified Statisticians with background in sampling and experience in collection and analysis of Agricultural Statistics.

Appointment 2 years. Salary (UK taxable) to be arranged plus tax-free overseas allowance in range £1025—£2190 pa. (Ref 328X).

Extension Agronomist

Sudan

At Nuba Mountains Agricultural Production Corporation to assist with implementation of field programmes. Applicants should have University degree in Agriculture or related science, with at least 5 years' experience of crop production and extension work in developing country.

Appointment 3 years. Salary in range £7000—£8500 pa plus tax-free overseas allowance in range £1755—£4555 pa. (Ref 331X).

The posts are wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowance other benefits normally include paid leave, free family passages, childrens education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to:—

Appointments Officer,
MINISTRY OF OVERSEAS DEVELOPMENT,
Room 301, Eland House,
Stag Place, London SW1E 5DH.

1412(A)

HELPING NATIONS HELP THEMSELVES

UNIVERSITY OF THE
WEST INDIES—TRINIDAD

Applications are invited for the post of LECTURER/ASSISTANT LECTURER in CROP PRODUCTION, FACULTY OF AGRICULTURE. Applicants should possess a higher degree in Agriculture or Plant Sciences and experience in teaching and research in the tropical field or horticultural crops. Preference will be given to candidates with knowledge of and experience in Crop Production systems practised in the Caribbean Region. The applicant will be expected to assume duties not later than July 1978.

Salary Scales: 1977/78: Lecturer: TT\$19,071 to TT\$29,799 p.a. Assistant Lecturer: TT\$15,480 to TT\$16,974 p.a. (£1 sterling = TT\$4.66) F.S.S.U. Unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance of 10% of pensionable salary. Up to five full economy passages on appointment and on normal termination. Study and Travel Grant. Detailed application naming three (3) referees to Secretary, U.W.I. St Augustine, Trinidad. Details of post sent to all applicants. 1460(A)

UNIVERSITY OF TORONTO. Department of Mathematics. PROFESSOR. Demonstrate record of scholarly achievement. Teaching graduate and undergraduate courses. Direction of Ph.D. theses and otherwise maintaining a high standard of research in the Department. Salary negotiable, subject to budgetary approval. Effective date of appointment July 1, 1978. Application should be made as soon as possible to: The Chairman, Department of Mathematics, University of Toronto, Toronto, Canada, M5S 1A1. 1446(A)

UNIVERSITY OF
TASMANIA

LECTURESHIP/SENIOR
LECTURESHIP IN
PATHOLOGY

Applications are invited for this position with the salary scale as follows:

Senior Lecturer—\$A19,971 to 4 by 666 to 1 by 664 to \$23,299; Lecturer—\$A14,851 to 3 by 672 to 4 by 671 to \$19,551. An appointment will be offered from the beginning of 1979 within one of these grades, according to qualifications and experience. An additional loading is paid to medical staff with clinical responsibility. For this appointment, it is expected that the loading would be \$A5,000 p.a.

Applicants must have had experience in the practice of pathology and the successful appointee will be expected to contribute to the Pathology services of the Royal Hobart Hospital, where he will be given an appropriate appointment.

Intending applicants are invited to write to Professor R. A. Rodda, Department of Pathology in the University, for any further information they may require.

The University reserves the right to offer a short-term contract appointment, or a probationary appointment, rather than an appointment with immediate tenure. Conditions of appointment and application forms obtainable from Association of Commonwealth Universities (Appts). 36 Gordon Square, London WC1H 0PF. Applications close on March 31, 1978. 1427(A)

UNIVERSITY OF NAIROBI
KENYA

Applications are invited
for the post of

SENIOR LECTURER

in the

DEPARTMENT OF ZOOLOGY

Applicants should be zoologists with considerable teaching and research experience in ecology, vertebrate zoology, palaeontology, cell biology or immunology. Outstanding candidates with qualifications in other fields of Zoology will also be considered. The Department's main teaching and research interests are in ecology, comparative physiology, parasitology and hydrobiology (marine, freshwater and fish biology). Salary scale: K£2,988 to K£3,984 per annum (K£1=£1.30). The British Government may supplement salary in range of £4,128 per annum (sterling) for married appointee or £2,880 per annum (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Terms of service include superannuation scheme; medical aid scheme; family passages and various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent to Registrar, University of Nairobi, PO Box 30197, Nairobi, Kenya by March 7, 1978. Applicants resident in UK should send one copy to Inner University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 1407(A)

New Product Planning

Graduate Scientist

An opportunity has arisen for a young scientist to assist in the planning and co-ordination of the development of new medicinal products from the time of their identification to marketing.

The job involves preparing plans for the development of compounds, compiling and maintaining data on development projects and liaising between departments within the Company. He or she will act as secretary to key committees and be responsible for the production and distribution of appropriate documents for these committees.

Candidates will be graduates in a scientific discipline relevant to the pharmaceutical industry. Ideally, they will have some experience in a research environment and the ability to co-operate and communicate effectively with all levels and disciplines. 1978 Graduates will probably have insufficient experience for the position.

The post carries a competitive salary which will reflect the age and experience of the successful applicant; other benefits include pension and profit sharing schemes, and assistance with relocation expenses where appropriate to this very pleasant part of Hertfordshire.

Applications to: Dr I. Collins, Personnel Manager, Allen & Hanburys Research Ltd., Ware, Herts SG12 0DJ. Tel: Ware 3232. 1470(A)

**Allen & Hanburys
Research Limited**

SCIENCE RESEARCH COUNCIL ROYAL GREENWICH OBSERVATORY ASTROPHYSICS DIVISION

The Observatory has a vacancy for a Higher Scientific Officer to initiate and carry out observing programmes and theoretical interpretation of data in one or more of the following fields:

Stellar evolution, chemical composition of stars and stellar populations, galactic and extra galactic HII regions, star clusters, the structure and dynamics of normal and peculiar galaxies and of clusters of galaxies.

Observations will be made using Science Research Council and other facilities in the U.K. and overseas.

In addition the person appointed is likely to be involved in the design of instruments for astronomical research and in assisting visiting observers with observing and data reduction procedures.

Qualifications: Candidates should have a Ph.D. degree or equivalent qualification preferably with some post-doctoral experience in astrophysical research at a major observatory.

Salary: According to experience, within a range £3,745 to £4,976 per annum including supplements. The Council has a non-contributory pension scheme.

Application forms are available from: Mr J. Philcox, Royal Greenwich Observatory, Herstmonceux Castle, Hailsham, East Sussex BN27 1RP, telephone Herstmonceux 3171 and should be returned not later than March 24, 1978. 1472(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF MEDICAL PHYSICS

Applications are invited for the post of LECTURER in the above Department. Preference will be given to applicants already holding doctorate research qualifications and having experience in aspects of radiation physics.

Salary on the lecturer scale £3,333 to £6,655 (under review).

Application forms and further details may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 92/1/D. Closing date for applications March 17, 1978. Informal enquiries may be addressed to Professor R. E. Ellis, Department of Medical Physics, The General Infirmary, Leeds LS1 3EX. Tel: Leeds 32799, ext. 487. 1415(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF PHYSIOLOGY

Applications are invited for a post of TEMPORARY LECTURER in the above Department. The post is tenable for one year, and is available now. The Department has Science, Medical and Dental teaching commitments, and research interests in the major fields of mammalian physiology. Medical qualification would be welcome.

Salary in the range £3,333 to £4,403 (under review) of the scale for Lecturers.

Further details may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 104/5/D. Closing date for applications March 10, 1978. 1416(A)

THE UNIVERSITY OF LEEDS ASSISTANT LIBRARIAN

Applications are invited for a post of Assistant Librarian in the University Science Library. Candidates must be graduates in science or applied science with professional library qualifications or research experience.

Salary will be on the IA Scale for Senior Library Staff £3,333 to £5,627 (under review).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 116/7/D. Closing date for applications March 10, 1978. 1467(A)

UNIVERSITY OF EDINBURGH FACULTY OF MEDICINE LECTURER IN PHARMACOLOGY

Applications are invited for the post of Lecturer in the Department of Pharmacology as from October 1, 1978. This is a full-time appointment in which the successful candidate will be expected to make a research contribution. Salary on the scale £3,333 to £6,655. U.S.S. superannuation.

Applications (six copies) giving the names of two referees should be sent, not later than March 17, 1978, to the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, from whom further particulars may be obtained. Please quote Reference 1011. 1418(A)

BIOCHEMIST

An opportunity exists in this Pharmaceutical Research Company for a recent Honours Graduate in Biochemistry to join a small team involved in the preparation of enzymes from biological materials.

Some experience of protein purification techniques is desirable but a capacity to work with a minimum of supervision after training is of greater importance.

Application forms are available from The Company Secretary, Biorex Laboratories Ltd., Biorex House, Canonbury Villas, London N1 2HB. 1394(A)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

A TECHNICIAN is required to work in the Academic Department of Surgery at the Royal Free Hospital, Hampstead. Experience in tissue culture and biochemistry desirable. Qualifications—H.N.C. or equivalent. Salary on Whitley Council Scale.

Application forms available from The School Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP (or telephone 01-837 5385. Ext. 8 or 10). Closing date: March 2, 1978. 1439(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London) RESEARCH ASSISTANT (IMMUNOLOGY)

A research assistant is required in the new section of Immunology to work on aspects of human 'in vitro' cellular immunology. This post would be suitable for some with laboratory experience in immunology or a related subject and who is able to carry out research projects without close supervision. For further details apply with curriculum vitae to Sector Administrator, Department of Biochemistry, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. 1396(A)

UNIVERSITY MARINE
BIOLOGY STATION
MILLPORT
RESEARCH ASSISTANT

is required to work on the behaviour of subtidal burrow building macrofauna under the direction of Dr R. J. A. Atkinson. The appointment (N.E.R.C. supported) is for two years from March 1, 1978 or as soon thereafter as possible. Salary £2,904 with one increment of £215 after the first year.

Applicants should have an honours degree in Zoology or Biology and diving qualifications to B.S.A.C. 2nd Class or equivalent.

Applications (three copies) together with the names of three referees, one of whom has personal knowledge of diving ability, should be received no later than February 24, 1978 by the Secretary, University Marine Biological Station, Millport, Isle of Cumbrae, Scotland KA28 0EG. 1395(A)

SWISS FEDERAL
INSTITUTE OF
TECHNOLOGY (ZURICH)
RESEARCH ASSOCIATE OR
FELLOW IN
BIOCHEMISTRY

Applications are invited for the post of Research Associate or Fellow to work on a project concerning protein sequence determinations. Experience in biochemistry, especially in the techniques of protein sequence determination is essential. A Ph.D. or equivalent is preferable. The project is supported for 2 years by a grant of the Swiss Federal Institute of Technology. The salary will be SFr. ~40,000.-/year (\$ ~20,000.-/year, £ ~15,000.-/year).

Applications, including the names of two referees, should be sent to Professor Dr K. H. Winterhalter, Labor für Biochemie I, Universitätstr. 16, 8092 Zurich, from whom further details may also be obtained. Please quote Reference 1308 (A).

UNIVERSITY OF
BIRMINGHAM
DEPARTMENT OF
BIOCHEMISTRY

Applications are invited for a post of:

LECTURER IN
BIOCHEMISTRY

tenable from October 1978, or earlier. The successful candidate will be expected to participate in the general and specialised teaching programmes of the Department which provides courses for science, medical and dental undergraduates. Excellent facilities are available for most types of biochemical research.

Salary within the range £3,333 to £4,403 p.a. (plus U.S.S.), depending on age, qualifications and experience.

Applications (3 copies) naming 3 referees should be sent by March 6, 1978 to the Assistant Registrar (Senate), University of Birmingham, P.O. Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. 1311(A)

POSTDOCTORAL
RESEARCH POSITION

Two-year appointment available for recent Ph.D. in Physiology or Biology to work on oxygen transport to the eye and retina. Will also be involved in other aspects of retinal physiology. Background or knowledge of electrophysiology helpful.

Excellent salary and benefits.

Send resume to John J. Weiter, M.D., Department of Ophthalmology, Tufts New England Medical Center, 171 Harrison Avenue, Boston, Mass. 02111.

An Equal Opportunity Employer, M/F. 1411(A)

Wellcome

Production Manager/ Senior Scientist

... Reagents Bulk Production

This is a senior appointment with responsibility for the day-to-day running of the Bulk Production areas; producing a complete range of *in vitro* diagnostic reagents covering Immunology, Bacteriology, Serology and Clinical Chemistry.

Reporting to the Production Manager, Wellcome Reagents Limited, the successful candidate will require extensive scientific and managerial skills to maintain and improve on present production performance, both by the application of approved management techniques and the introduction of improved production methods.

Candidates, probably not less than 35 years old, will hold a first (or higher) degree or equivalent qualification, and be able to demonstrate previous experience in the preparation and use of *in vitro* biological diagnostic reagents.

Salary will be commensurate with ability and experience, and will attract those presently earning in excess of £5,500 p.a.

The Wellcome Research Laboratories are situated in pleasant parkland surroundings within easy reach of Bromley and Beckenham and about 12 miles from Charing Cross. Conditions of employment are attractive and include four weeks' holiday, pension and sick pay schemes, subsidised canteen and excellent sports and social facilities and generous assistance with relocation expenses where appropriate.

Please write giving brief details of qualifications and experience to R. V. Sutton, Personnel Officer, The Wellcome Research Laboratories, Langley Court, Beckenham, Kent BR3 3BS, quoting reference no. U.852.

1471(A)

HEAD OF DIVISION
OF IMMUNOGENETICS

A vacancy exists for the post of HEAD OF DIVISION OF IMMUNOGENETICS (Salary according to AH3). The successful applicant will be responsible for teaching immunogenetics and serogenetics. The applicant should have had experience in the field of transplantation antigens in order to be able to perform antigen typing within the framework of hereditary biological diagnosis. The Institute promotes research in the field of mammalian development. The experimental work of the applicant should therefore be mainly directed to problems of the cell surface during development.

Applications, together with selected reprints should be sent before April 1, 1978 to:

Dekanat der Medizinischen Fakultät der Universität Göttingen
Wilhelmsplatz 2
3400 Göttingen
West Germany 1392(A)

POSTDOCTORAL FELLOW
MICROBIOLOGY

Applications are invited for a post-doctoral fellow to work on structure and genetics for influenza virus. Preference will be given to applicants with experience in the field of RNAs. Please send curriculum vitae and references to: Dr Peter Palese, Microbiology Department, The Mount Sinai School of Medicine, 100 Street and Fifth Avenue, New York, N.Y. 10029, USA. An equal opportunity employer. 1405(A)

THE UNIVERSITY OF
CALIFORNIA
Faculty position in
AQUACULTURE
ASSISTANT OR
ASSOCIATE PROFESSOR

Twenty per cent. teaching; 80 per cent. research. Ph.D. in a specific area of fisheries biology, with strong background in larval rearing of fish with species endemic to the Sacramento River, California, and interest in developing research and teaching in fish aquaculture. Interest in species other than salmonids preferred. Teaching at both undergraduate and graduate levels expected. Applicants should submit résumé, publication list, letter describing interests, three letters of reference, and for recent Ph.D.s, undergraduate and graduate transcripts to: GRAHAM A. E. GALL, ASSOCIATE DIRECTOR AQUACULTURE, DEPARTMENT OF ANIMAL SCIENCE, UNIVERSITY OF CALIFORNIA, DAVIS, CA 95616 PRIOR TO APRIL 30, 1978. Position available July 1, 1978. The University of California is an Equal Opportunity/Affirmative Action Employer. 1456(A)

PART-TIME
RESEARCH NURSE

20 hours per week to assist in research into gastro-intestinal and vascular disorders. Previous research experience not necessary. For further details and informal visit call St James' Hospital, Batham. 672-1222 Ext. 132. 1461(A)

UNIVERSITY OF
QUEENSLAND
Australia
LECTURER IN
VETERINARY ANATOMY

Applicants should hold appropriate academic qualifications for the position, should have previous experience in teaching and research and should present evidence that their teaching and research ability is of the highest quality. Preference will be given to applicants who hold a qualification in veterinary science. The successful applicant will be expected to teach the gross anatomy of domesticated animals as well as embryology and histology. March 20, 1978.

Salary: \$A14,851 to \$A19,551 per annum. Other Benefits: Study Leave, Superannuation, housing assistance, travel and removal expenses.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Acpus), 36 Gordon Square, London WC1H 0PF. 1428(A)

JUNIOR TECHNICIAN

preferably with some experience of cell culture and virology, required in Department of Microbiology. Salary on scale £2,044 to £2,654, or £2,155 to £2,758, according to age and qualifications, plus £354 London Weighting.

Apply in writing, stating age, and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. M.C.1. 1410(A)

FELLOWSHIPS IN ENVIRONMENTAL RESEARCH

The Monitoring and Assessment Research Centre at Chelsea College, University of London is carrying out a research programme on pollution assessment.

The broad objectives of the programme are to improve understanding of the movement and effects of pollutants in the environment so that harm to man and his resources from pollution can be estimated and assessed.

The work is sponsored by the United Nations Environment Programme and The Rockefeller Foundation and has the support of the Scientific Committee on Problems of the Environment.

Applications are invited for senior visiting research fellowships from scientists who could make contributions in one of the following work areas:

1. The development and use of environmental transport models, along various critical pathways, which will enable the prediction of total exposure of man and other important targets to certain pollutants.
2. The evaluation of the effects of environmental pollution in particular to
 - * review current approaches to determine dose-response relationships for humans and other biota and the toxicological and epidemiological information required;
 - * use dose-response relationships to define exposure limits;
 - * develop methods of assessing the harm to intact ecosystems resulting from environmental stress.

In the first instance, appointments will be made for a period of one to six months. These fellowships are particularly suited to applicants wishing to come on sabbatical leave or on a similar basis. Financial support will be considered by M.A.R.C. on a case by case basis but may include contributions towards travel expenses as well as a *per diem* allowance during the term of the appointment.

Potential applicants may obtain further information from the Director, Monitoring and Assessment Research Centre, The Octagon Building, 459A Fulham Road, London SW10 0QX to whom applications together with *curriculum vitae* and the names of two referees should be sent. (1390)A

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(University of London)

Denmark Hill

London SE5 8RX

DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

Applications are invited from graduates or suitably qualified people for the post of Research Technician on a project for which experience of at least one year in tissue culture and cytogenetics is essential. In addition, histological and histochemical techniques will be applied in this area of pre-natal diagnosis of inherited diseases.

Starting salary £3,112 inclusive.

For informal enquiries please contact Dr J. Singer on 01-274 6222 extension 2349. Applications in writing giving full details of qualifications and experience should be sent to the Secretary of the Medical School at the above address. Closing date March 2, 1978. 1464(A)

RESEARCH ASSISTANT IN ATMOSPHERIC SCIENCE (AERONOMY)

The Department of Atmospheric and Oceanic Science of the University of Michigan has a postdoctoral research position available in the area of terrestrial and planetary aeronomy. This position involves analysis and interpretation of data obtained from a variety of space missions (e.g. Pioneer-Venus, Voyager, Dynamics Explorer, etc.). This work is to be carried out in collaboration with Professors T. M. Donahue and A. F. Nagy. Send resumes to: University of Michigan, Office of Professional and Administrative Staff Services, 1020 "SN" L.S. and A. Building, Ann Arbor, Michigan 48109. A non-discriminatory, affirmative action employer. 1441(A)

YALE UNIVERSITY SCHOOL OF MEDICINE NEUROBIOLOGIST

The Department of Physiology is seeking a neurobiologist at the Assistant Professor level. Preference will be given to individuals whose work relates to the function of the central nervous system. The position permits considerable time for research; opportunities exist for graduate and medical student teaching.

Please send curriculum vitae, bibliography and the names and addresses of three references to:

CHAIRMAN
Neurobiologist Search Committee
Department of Physiology
Yale University School of Medicine
333 Cedar Street
New Haven, Conn. 06510

Applications from women and members of minority groups are encouraged. An Equal Opportunity/Affirmative Action Employer.

Applications should be received before March 30, 1978. 1419(A)

EUROPEAN DISTRIBUTOR REQUIRED

We are looking for an experienced distributor who will actively market our products in the European research community. Cedarlane Laboratories is a Canadian manufacturer of specialised antisera, complement, and other reagents used primarily for immunological research. If your company is familiar with this market and would like to discuss distribution, contact:

Dr A. J. Farmilo,
Cedarlane Laboratories Limited,
493A Wellington Road South,
London, Ontario,
CANADA N6C 4R3 1443(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF ANATOMY

Applications are invited from graduates in medicine, medical or biological science for the post of LECTURER in the Department of Anatomy (Professor J. J. T. Owen). The Department has broad research interests but preference will be given to candidates with research interests in the field of immunobiology. Training in the teaching programme of the Department will be given if necessary, and previous experience is not essential.

Salary on the scale £3,333 to £6,655 plus superannuation.

Further particulars about the post can be obtained from Professor Owen. Applications should be sent to the Assistant Registrar, the Medical School, Birmingham B15 2TJ, giving the names of three referees, by March 17, 1978. 1426(A)

CENTRAL BIRMINGHAM HEALTH DISTRICT THE CHILDREN'S HOSPITAL, TECHNICIAN or BIOLOGICAL SCIENCE GRADUATE

required for a research post. The successful applicant will be concerned with a leukaemia and non-Hodgkins Lymphoma study. Previous experience in immunology helpful but not essential. Appointment for one year in the first instance.

Salary according to experience and qualifications.

For further details and an application form please contact Dr F. G. H. Hill, Consultant Haematologist, Haematology Department, The Children's Hospital, Ladywood Middleway, Birmingham B16 8ET. Telephone: 021-454 4851. 1402(A)

TECHNICIAN, H.N.C. or science graduate, to help with a grant financed project concerning antibodies in tumour immunology at the Institute of Cancer Research, Sutton, Surrey. Knowledge of protein chemistry and immunological techniques would be an advantage.

Salary in scale £2,982 to £4,258 p.a. plus London Allowance of £354 p.a., depending on qualifications and experience.

Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/40. 1438(A)

HERIOT-WATT UNIVERSITY DEPARTMENT OF ELECTRICAL AND ELECTRONIC ENGINEERING SCANNING ELECTRON MICROSCOPY X-RAY ANALYSIS Applications are invited for an EXPERIMENTAL OFFICER

to operate a scanning electron microscope with an X-ray analyser attachment.

Applicants should have supporting experience in related fields such as electronics, photography and data analysis. The Department provides a service for research, on dielectric, metallurgical, geological and biological materials, much of it in connection with the Heriot-Watt/S.R.C. Centre for Marine Technology. The Experimental Officer will be responsible for achieving high quality results for such research but will be encouraged to develop his own research interests.

Salary scale: Research Staff—Range 1A £3,333 to £5,626. (Salary scales currently under negotiation).

Please apply in writing for an application form to the Staff Officer, Heriot-Watt University, Chambers Street, Edinburgh EH1 1HX. 1440(A)

South African Astronomical Observatory Research Posts

Two temporary (3 year) or permanent research posts are available at the South African Astronomical Observatory which is financed jointly by the Council for Scientific and Industrial Research (South Africa) and the Science Research Council (United Kingdom). The astronomy staff of the SAAO is based in Cape Town where the main offices, etc. are situated. Most observing facilities are at Sutherland (Cape Province) where the SAAO has 1.9m; 1.0m; 0.75m and 0.5m reflectors equipped with a range of modern instrumentation.

Preference will be given to applicants with research experience and a Ph.D. degree or equivalent, and whose main interest is observational astronomy.

Salary will be determined by qualifications and experience. Assistance will be given with transfer expenses.

Fringe benefits include 39 days leave per annum (maximum), generous sick leave, and medical and pension schemes.

Enquiries should be directed to the Office of the Scientific Counsellor,

South African Embassy:

THE LONDON HOSPITAL MEDICAL COLLEGE (University of London) BONE AND JOINT RESEARCH UNIT

RESEARCH ASSISTANT (IMMUNOCHEMIST)

Applications are invited for the post of Research Assistant, from graduates with a suitable qualification, to assist in research on human protein immunochromatography. Further, an interest in cellular immunology will be an asset. This post, which is for a limited duration, is financed by a Grant from the M.R.C. to Dr E. J. Holborow from whom further details may be obtained, telephone no. 01-247 5454 Ext. 420. Initial salary will be within the range £2,904 to £3,761 (under revision) plus £450 London Allowance and superannuation under the U.S.S./N.H.S.

Written applications (quoting reference RA/IM/2/78) to The Secretary, The London Hospital Medical College, Turner Street, London E1 2AD within 21 days. 1452(A)

UNIVERSITY OF LONDON KING'S COLLEGE DEPARTMENT OF BIOCHEMISTRY CHIEF TECHNICIAN Grade 7

Applications are invited from appropriately qualified (at least H.N.C.) technicians with at least 10-12 years experience for this responsible post. Preferred age 30-40. The successful applicant will be in charge of the organisation and supervision of all technical services under the general direction of the Head of Department.

Salary on scale £4,719 p.a. rising to £5,242 p.a. inclusive. Application form and further particulars from: The Head Clerk, Ref. 191123/N, King's College London, Strand WC2R 2LS. 1423(A)

GLASSBLOWER required for construction and repair of chemical glassware. Write giving details of experience: Maybridge Chemical Co. Ltd. Tintagel, N. Cornwall. 1421(A)

ST JUDE CHILDREN'S RESEARCH HOSPITAL

Fellowships available July 1, 1979 at St Jude Children's Research Hospital, Memphis, TN for physicians or basic scientists: David A. Karnofsky Fellowship for training beyond postdoctoral level in cancer research and Leon J. Journey Fellowship for postdoctoral training in biomedical research.

Areas of training include: biochemistry, hematology-oncology, immunology, infectious diseases, nutrition and metabolism, pathology, pharmacology, radiology, surgery and virology.

Stipends: \$12,000 to \$18,000. Open to international competition. September 1, 1978 deadline. Write: Medical Director, St Jude Children's Research Hospital, P.O. Box 318, Memphis, Tennessee 38101. 1425(A)

THE UNIVERSITY OF SHEFFIELD

DEPARTMENT OF PHYSIOLOGY

Applications are invited from men and women for a post of RESEARCH ASSISTANT in the above Department tenable as soon as possible for up to three years. The successful applicant would be required to join a group working in one of the following areas: Central nervous control of gastrointestinal function.

Secretory mechanisms of exocrine glands.

Other areas of interest would, however, be considered. Initial salary in range £2,904 to £3,547 a year on the R&A Range IB scale rising to £4,190 a year. Particulars from the Registrar and Secretary, the University, Sheffield S10 2TN to whom applications (5 copies), should be sent by March 3, 1978. Quote Ref. R.73/G. 1400(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London)

BIOPHYSICAL ENDOCRINOLOGY UNIT, DEPARTMENT OF PHYSICS AS APPLIED TO MEDICINE

Applications are invited for a Research Assistant 1A; starting salary, depending on age and qualifications, of £3,783 to £4,212 including £450 per annum London Allowance.

Suitable for a postdoctorate, this post will be available for two years, funded by a Medical Research Council Programme Grant. The project will involve the in vitro assay of pressor substances including the preparation and use of dispersed muscle cells. Preparation and investigation of other biological cells may be involved.

Applications, together with the names of two referees should be sent to the Secretary, Department of Physics as Applied to Medicine, Windeyer Building, Cleveland Street, London W1P 6DB. 1462(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London) TECHNICIAN

required to assist with laboratory research on the physiology of animals including the nervous system and studies on the secretion of mucus. Experience desirable, but not essential since training in the various techniques will be provided. The grading of the post (up to a maximum of University grade 2B £3,155 p.a.) will be determined according to qualifications and/or experience. Application forms available from the Establishment Officer (Ref. Phys), St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. 1459(A)

ST THOMAS' HOSPITAL MEDICAL SCHOOL (University of London) London SE1 7EH

APPLIED NEUROPHYSIOLOGY

A Research Fellowship provided by the Medelec Co. Ltd. is available at the Sherrington School of Physiology and the Department of Rheumatology (Electrodiagnosis), St Thomas' Hospital, London SE1 7EH. Medical graduate to be appointed for 2 to 3 years, should have some experience of electrodiagnosis. Enquiries to Professor A. Taylor, Sherrington School.

1458(A)

FELLOWSHIPS

ROYAL POSTGRADUATE MEDICAL SCHOOL POSTDOCTORAL BIOCHEMIST/ PHARMACOLOGIST

Applications are invited for an M.R.C. Postdoctoral Research Fellowship, tenable for up to three years, for studies on aspects of the role of prostaglandins in human disease. Candidates should possess a Ph.D. in Biochemistry, Pharmacology or related subject and should have experience in (or a keen interest in learning) those analytical techniques, e.g. gas chromatography-mass spectrometry, employed in the determination of trace components in biological fluids.

Salary up to £4,256 per annum inclusive.

Applications, enclosing a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible to the Personnel Officer, R.P.M.S., 150 Du Cane Road, London W12 0HS, quoting ref. no. 20/466/N. 1463(E)

nature

Travelling Fellowships

Each year we have £1,500 available for travelling fellowships to be awarded to scientists or journalists who want to travel on *Nature's* behalf to parts of the world where we do not as yet have strong editorial contacts.

Sabbaticals

There are occasional opportunities for scientists to spend a period of a month or two in the *Nature* office working alongside our editorial staff.

We are at present inviting applicants for these positions for the coming year. Further details and application forms are available from The Editor, *Nature*, 4 Little Essex Street, London WC2. 1429(E)

FELLOWSHIPS—continued

UNIVERSITY OF
NOTTINGHAM
SCHOOL OF AGRICULTURE
POSTDOCTORAL
FELLOWSHIP IN
REPRODUCTIVE
PHYSIOLOGY

Applications are invited for a post-doctoral fellowship to join a research team investigating problems of reproduction in lactating dairy cows. The project involves liaison with dairy farmers and veterinary surgeons in studies on the causes and incidence of bovine subfertility. A knowledge of radioimmunoassay procedures an advantage.

Applications, giving the names of three referees together with a curriculum vitae to be submitted to Prof. G. E. Lamming, University of Nottingham School of Agriculture, Sutton Bonington, Nr. Loughborough, Leics. by March 1, 1978. 1451(F)

RESEARCH FELLOWSHIP
Imperial Cancer Research Fund
Laboratories, Mill Hill, NW7

A postdoctoral Fellow is required to join a group working on the genetic and biochemical analysis of certain heat activated loci in *Drosophila melanogaster*, using cloned DNA fragments to investigate their organisation and expression.

Appointment will be for two years in the first instance with possible extension for a third year. Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr D. Ish-Horowitz (01-959 3236). Applications with curriculum vitae and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by March 17, 1978. 1475(E)

SYMPOSIUM

SYMPOSIUM

on

"THEORY AND PRACTICE
IN AFFINITY TECHNIQUES"

APRIL 10-12, 1978

The workshop will be held at the Max-Planck-Institut für experimentelle Medizin, Göttingen, West Germany.

Lectures and Round Table Discussion will be on special features in Affinity Chromatography (recent developments) and Affinity labelling of enzymes, receptors and hormones, Radioimmunoassay, Enzyme Immunoassay.

Speakers will include:

C. R. Lowe (U.K.), F. von der Haar (Germany), P. D. G. Dean (U.K.), R. L. Easterday (USA), J. R. Coggins (U.K.), R. Abeles (USA), H. Fasold (Germany), F. C. Hartman (USA), M. Wilchek (Israel), E. Kuchler (Austria), D. G. Knorre (USSR), A. Maclieck (Germany), R. Leute (USA), Lequin (Netherlands).

Participation:

Applications should reach Dr P. V. Sundaram, Max-Planck-Institut für experimentelle Medizin, D-3400 Göttingen, Hermann-Rein-Straße 3, West Germany, before March 20, 1978, declaring research interests. A registration fee of DM 150, will be charged. Hotel arrangements will be left to participants but hotel list supplied. Participants will be responsible for their travel and living expenses.

Organizers:

Dr P. V. Sundaram and Professor F. Eckstein
(Telephone: 0551/303 274). 1444(M)

STUDENTSIPS

UNIVERSITY OF
ABERDEEN
FACULTY OF MEDICINE
RESEARCH
STUDENTSIPS

Applications are invited from recent first or upper second class honours graduates in a biological science subject, and from those who expect so to graduate in 1978, for research studentships established by the Faculty of Medicine from its Medical Endowment Funds. Successful applicants will study for the degree of Ph.D. on an approved subject in one of the Departments of Biochemistry, Developmental Biology, Pathology, Pharmacology or Physiology, commencing in October 1978.

The value of the studentship is £1,475 p.a. (for students living away from home) with payment of tuition fees and other allowances.

Application forms and further particulars of the projects may be obtained from D. K. Yule, University Office, Regent Walk, Aberdeen AB9 1FX to whom applications should be submitted by March 17, 1978. 1468(F)

THE WEST OF SCOTLAND
AGRICULTURAL COLLEGE
Crichton Royal Farm,
Dumfries

RESEARCH STUDENTSHIP

Applications are invited for Research Studentship at the above experimental husbandry farm, to study herbage production and its utilisation by dairy cattle. The current value of the award, which will be tenable for up to three years, is £1,478 p.a. plus fees and approved travel expenses.

Applicants should have a first or second class honours degree in agriculture or agricultural science and the successful applicant will be required to register for a higher degree.

Further details may be obtained from the Secretary, The West of Scotland Agricultural College, Auchincruive, Ayre KA6 5HW, with whom applications should be lodged by March 17 1978. 1457(F)

COURSES

F.E.B.S. ADVANCED COURSE No. 54

MITOCHONDRIAL BIOGENESIS IN
ANIMAL DEVELOPMENT

JUNE 10-25, 1978, KOTOR, YUGOSLAVIA

INSTITUTE FOR BIOLOGICAL AND MEDICAL SCIENCES
MONTENEGRO,

UNIVERSITY OF TITOGRAĐ (YUGOSLAVIA)

INSTITUTE OF BIOLOGICAL CHEMISTRY AND

CENTRO C.N.R. STUDIO SUI MITOCONDRI

E METABOLISMO ENERGETICO

UNIVERSITY OF BARI (ITALY)

The experimental program is as follows:

- Isolation of mitochondria from animal cells
- Isolation of mitochondrial DNA
- Endonuclease cleavage map of mitochondrial DNA
- Cloning of mitochondrial DNA fragments
- Extraction and characterisation of mitochondrial components
- Mitochondrial macromolecular synthesis during early developmental stages
- Nuclear control on mitochondrial biogenesis: anucleation and related techniques.

The speakers will include:

G. Bernardi (Paris), H. Bresch (Hannover), R. Butow (Dallas), G. Giudice (Palermo), V. Glišin, (Kotor), A. M. Kroon (Groningen), E. Quagliariello (Bari), C. Saccone (Bari), H. Weiss (Heidelberg).

The reaching staff will include:

N. Moškov, V. Deretić, M. Solomun (Kotor), M. Greco, G. Pepe, G. Del Prete (Bari), H. Bakker (Groningen), A. Nicotri (Roma), A. M. Rinaldi (Palermo).

The language of the course is English. Attendance at the course will be limited to 20 participants. Preference will be given to applicants from the European area at the postdoctoral level with research experience who plan to engage in investigations of the role and function of Mitochondrial Biogenesis in animal cells.

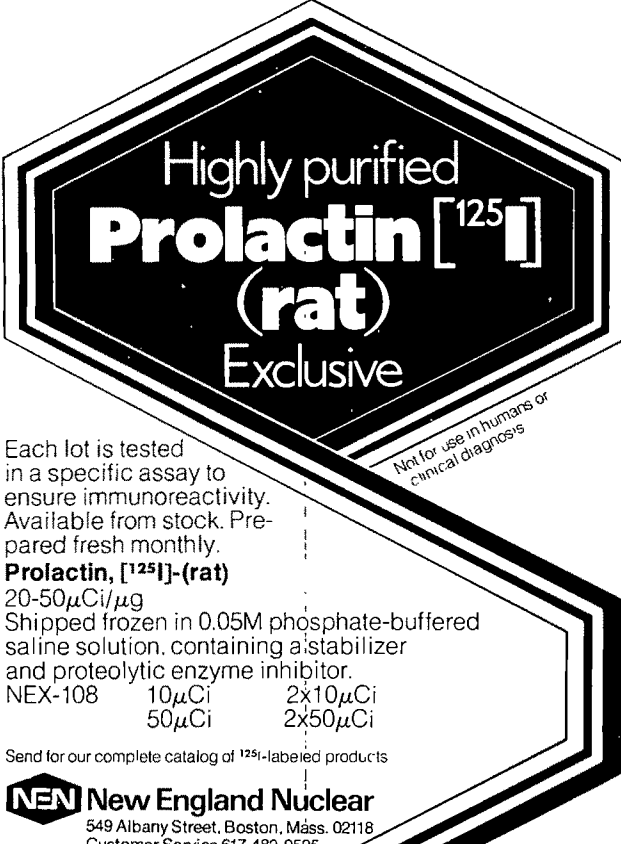

The participation fee will be 125,000 It. lire or 2,900 Yu. dinars.

The participants are expected to pay their own travel. The food and lodging expenses will be covered by the organisers. To successful applicants few accommodation fellowships will be awarded.

Applications with short curriculum vitae and any information which might help in the evaluation of the application should reach by April 15: Dr Vladimir Glišin, P.O. Box 80, Kotor, Yugoslavia 81330 and/or Dr Cecilia Saccone, Istituto di Chimica Biologica, Via Amendola 165/A, Bari (Italy).

ORGANISERS: Vladimir Glišin, Ernesto Quagliariello and Cecilia Saccone

OTHER SPONSORSHIPS: E.M.B.O., C.N.R. (Italy), University of Titograd (Yugoslavia), University of Bari (Italy). 1474(D)

A CHANGE IN MIND

A MEDICAL TRILOGY FROM YORKSHIRE TELEVISION

Three documentaries from Yorkshire Television's science unit which will reflect changing attitudes to the mind in the fields of neurology, psychiatry and psychology.

This week WHAT MAKES YOU TIC?

A report on...

Tourette's Syndrome, the medical enigma in which the sufferer is beset with a ceaseless stream of tics, grimaces, gesticulations, exclamations, compulsive touchings and noises, some of which echo and imitate the world around. "The most complex, the most inventive, the most creative disorder known or imaginable — a striking example of truth being stranger than fiction," says Dr. Oliver Sacks, the neurologist.

and go for the big name—**

MSE

Just two examples—backed by MSE's rigid safety and service standards*

CHILSPIN

Bench-top Refrigerated Centrifuge

- ☐ Speeds up to 6100 RPM (6030 x g)
- ☐ Temperature control over range +4°C to +15°C by $\frac{1}{4}$ HP hermetic cooling unit
- ☐ Stepless speed control
- ☐ Powerful motor giving fast acceleration: electric brake for smooth deceleration
- ☐ Pneumatic lid stay: smooth action, self-locking – supports lid in the open position
- ☐ Accepts all rotors and accessories used on the popular MSE Super Minor – maximum tube size 100ml, maximum total capacity 800ml
- ☐ Easy conversion to floor-standing model by using optional trolley with lockable castors

Publication No. 535/A

MINOR 'S'

Successor to the world-famous MSE Minor Centrifuge

- ☐ Clean, modern, compact design
- ☐ Improved performance – speeds up to 4000 RPM (2610 x g)
- ☐ Automatic Timer: 1–26 minutes
- ☐ Optional manual switch position for longer runs
- ☐ Electric brake for smooth, fast deceleration
- ☐ Accepts all rotors and accessories of the MSE Minor
- ☐ Mains on/off Lid Switch: locks lid until rotor is stationary, and centrifuge can be started only with lid correctly closed

Publication No. 534/A

* MSE's operational safety standards are probably the most rigid in the world – and for service there are 35 field engineers in the UK alone. Overseas, a world-wide network of Distributors offer a comprehensive after-sales and spares service from factory-trained engineers.

Does it change weight when you heat it?

Put it into a Stanton Redcroft Thermobalance and get a direct plot of weight versus temperature up to 1500°C.

Complete sample runs can be done in about half-an-hour. The TG-770 gives choice of heating rates up to 50°C per minute, with only 10 minutes for cooling back to ambient.

This speed, plus exceptional ease of use, makes the TG-770 ideal for routine quality control as well as for research and development, on things like inorganics, metals, minerals, clays and

soils, catalyst materials and supports, plastics, polymers and polymer additives including flame retardants, food stuffs, fats and lipids, medical specimens including gall stones and teeth structures, stability studies, electronic components, brake linings, oxidation and gaseous interactions.

A DTG unit can also be added to the 770 equipment to give the rate of weight change, which is extremely useful for kinetic work and in evaluating rapidly changing reactions.

Our own team of chemists looking at new developments in thermogravimetry can give valuable advice on your special interest and also carry out work under contract.

Stanton Redcroft also manufacture differential thermal analysers, temperature programmers and furnaces, thermocouples and flammability test equipment.

Full details from Stanton Redcroft, Copper Mill Lane, London SW17 0BN. Telephone 01-946 7731. Telex 8811417.

Stanton Redcroft

Guide to authors

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to e^a if '*a*' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unlettered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in 258, 1 (1975) and 264, v, 11 Nov. (1976).

Induction of IgG production in human B lymphoblastoid cell lines with normal human T cells	T. Kishimoto, T. Hirano, T. Kuritani, Y. Yamamura, P. Ralph and R. A. Good	756
Transplantation tolerance induced in foetal mouse thymus <i>in vitro</i>	J. H. Robinson and J. J. T. Owen	758
Regeneration of reduplicated limbs in contravention of the complete circle rule	J. M. W. Slack and S. Savage	760
Local perfusion of noradrenaline maintains visual cortical plasticity	J. D. Pettigrew and T. Kasamatsu	761
Connectivity changes in a class of motoneurone during the development of a nematode	J. G. White, D. G. Albertson and M. A. R. Anness	764
Dopamine receptors localised on cerebral cortical afferents to rat corpus striatum	R. Schwarcz, I. Creese, J. T. Coyle and S. H. Snyder	766
Coenzyme A is a purine nucleotide modulator of acetylcholine output	M. A. Cook, J. T. Hamilton and F. K. Okwuasaba	768
Localisation of gastrins to neuro- and adenohypophysis	J. F. Rehfeld	771
Dual action of erbium on transmitter release at the frog neuromuscular synapse	S. Metral, C. Bonneton, C. Hort-Legrand and J. Reynes	773
Monolayer coupling in sphingomyelin bilayer systems	C. F. Schmidt, Y. Barenholz, C. Huang and T. E. Thompson	775
ATP levels modify the activation of the Na pump by external cations in squid axons	L. A. Beauge and R. DiPolo	777
Transmission of Creutzfeldt-Jakob disease with scrapie-like syndromes to mice	E. E. Manuelidis, E. J. Gorgacz and L. Manuelidis	778
α -Crystallin polypeptides as markers of lens cell differentiation	A. J. M. Vermorken and H. Bloemendal	779
DNA polymerases during postnatal myocardial development	C. J. Limas and C. Limas	781
Photochemical (8 \rightarrow 8) coupling of purine nucleosides to guanosine	S. N. Bose, R. J. H. Davies, D. W. Anderson, J. C. Van Niekerk, L. R. Nassimbeni and R. D. Macfarlane	783

BOOK REVIEWS

Climates of Hunger: Mankind and the World's Changing Weather (R. A. Bryson and T. J. Murray)	John Gribbin	785
Self-Organisation in Non-Equilibrium Systems: From Dissipative Structure to Order through Fluctuations (G. Nicolis and I. Prigogine)	E. Neumann	785
Primate Ecology: Studies of Feeding and Ranging Behaviour in Lemurs, Monkeys and Apes (T. H. Clutton-Brock, editor)	John M. Deag	786
The Non-Classical Ion Problem (H. C. Brown)	M. C. Whiting	787
The Synthesis of Prostaglandins (A. Mitra)	C. J. Harris	787
International Cell Biology, 1976-1977 (B. R. Brinkley and K. R. Porter, editors)	A. V. Grimstone	788

Corrigendum

In the letter by P. E. Thorpe *et al* on p.752 of this issue, in Fig. 2 (a) it represents results from 1-h incubation with toxin (not 24h) and (b) represents its values from 24-h incubation.

For an explanation of the copyright lines that now appear at the bottom of many pages of *Nature*, please see page iii of the issue of 2 February 1978.

Find out why more researchers use S&S membranes for RNA/DNA hybridization, protein binding, DNA sequencing, and DNA blotting.

It won its reputation as B6, its old name. Now its catalog number is BA 85. They're two numbers for the same S&S nitrocellulose 0.45 μ m membranes. Either way, more researchers use S&S 0.45 μ m membranes than any other brand, in circles for adsorption of DNA strands and in sheets to blot DNA fragments from gels. As the laboratory standard, S&S is specified and preferred in most of the papers published on RNA/DNA hybridization, protein binding assays, or RNA or DNA sequencing.

If you don't know why, it's easy to find out. Fill in and mail the coupon to S&S, and receive a free sample of S&S BA 85—a 15cm square or circles up to 50mm diameter.

Coping with energy's nasty surprises

WHATEVER one may say about the general opacity of Whitehall and the British decision-making machine, Mr Tony Benn, Secretary of State for Energy, has ensured that his department is immune from much of the criticism. The proliferation of advisory councils, working groups, discussion documents and public meetings certainly means that Mr Benn shares his problems with the public-at-large; it probably also means that the decisions he makes are more enlightened, but whether those decisions turn out right in the long run is, in matters of energy, largely in the hands of people and events remote from Britain and British control. Thus it is reassuring that the one word which keeps cropping up in the Department of Energy's new consultative document *Energy Policy* (HMSO, £2.15) is 'flexibility'.

The Green Paper, although generated within the department, has also been discussed by the recently-formed Energy Commission, a body representing workers and management in the energy industry, and conservation, environment and consumer interests. Having been seen by many pairs of eyes both within the department and beyond it, the paper contains much middle-of-the-road common-sense, little that will surprise and a general commitment to keeping options open as long as possible. For instance, on nuclear strategy, "there is a need to have a capability to expand nuclear power rapidly in the late 1980s and 1990s if that course proves to be economically desirable and acceptable in other respects". Who would disagree with that?

Yet in spite of the genial optimism that generally surrounds the first major policy document to emerge from the department since North Sea oil flowed in any great quantity, there are problem areas; gas prices are perhaps the most serious. Natural gas is a relatively cheap resource which, since 1960, has progressively replaced coal as the domestic sector's most popular fuel; parenthetically, the supply of heat to the domestic sector has barely changed in 25 years, although the amount of useful heat consumed has risen by 75% with the switch away from coal and towards central heating. But the very cheapness of gas has acted, claims the department, against the best interests of a broadly based energy policy by prejudicing long term growth plans in the coal, electric and nuclear industries. So one of the decisions that has to be taken in the next two years or so, according to the Green Paper, is energy price structure, meaning how much the cost of gas should go up. Other short-term decisions with long-term implications are

- the fast reactor; UKAEA are bound soon to come up with a proposal for a demonstration commercial fast reactor which will have to go first to a public inquiry,
- whether a pipeline should be built to collect the heavier gas generally associated with North Sea oilfields,

- how much tougher conservation measures can be made, and
- the shape of future R & D, most notably where major efforts should be made in alternative energy sources.

Enthusiasts for alternative energy sources will be disappointed by the tone of the Green Paper. There are few concessions to 'softer' energy paths, and by the year 2000 alternative energy sources such as solar, waves, wind, tides and geothermal are seen as contributing a total of only 2%, if that, to the nation's needs. The recently installed Chief Scientist, Sir Hermann Bondi, is said to be looking right now at R & D strategy and it is to be hoped that he will put a little more optimism into these figures.

The one thing that the document does not do is discuss the possible nasty surprises which could cause a major derailment of the government's energy policy. Of course flexibility is meant to minimise the impact of nasty surprises but several could be thought of with disagreeable consequences. Two in particular might be mentioned. First, planning procedures have been getting distinctly more complex in recent years and there have been moves to make enquiries much wider-ranging than ever before. On major developments it is no longer simply a question of whether the local neighbourhood is going to be much inconvenienced—much broader policy questions are now being asked. Is it possible that a succession of questions, such as the opening up of new coalfields, should be decided against the government's intentions? If so, planning procedures could play havoc with a balanced energy policy. Second, the question of carbon dioxide and atmospheric warming seems by no means resolved. There is no doubt that the concentration is rising at present by more than 2% every ten years, and that there is no way of reversing this trend in the foreseeable future. In little more than fifty years' time, in some projections, the carbon dioxide concentration could be rising much more dramatically and be approaching double its present value.

There is no clear evidence today for a global warming from this cause, but, for all the uncertainties associated with climatic modelling, a doubling of the concentration is unlikely to occur without perceptible change. A warming of a degree or so, such as is often predicted, might be an agreeable bonus in temperate climates, but the real question mark is over the behaviour of the West Antarctic Ice Sheet (*Nature* 271, 321 (1978)). If this started to break up it would be far too late to prevent a catastrophic rise in sea level, so pressures for worldwide restraint in fossil fuel usage must come sooner rather than later. CO₂ might have as disturbing an influence on energy policy in the 1980s as did OPEC in the 1970s. □

Research in Greece

In this second article on Greek science, E M Pantelouris, assesses the effort put into non-university research.

MORE active Greek researchers work abroad than inside Greece. The recent death of one notable Greek scientist, K. Kotzias, who pioneered the treatment of Parkinson's disease with L-Dopa in the United States, only serves to emphasise this fact. And it was another Greek, George Papanicolaou, also working in the States before Kotzias' time, who first established the science of exfoliative diagnostic cytology.

Scientific papers, however, do come out of Greece. A computerised data search of the *Science Citation Index*—which may well cover 90% of the world's original research work—picked some 2,000 papers published in 1974-77 which are attributed to research centres in Greece (see table). Although there must be limitations to drawing conclusions from data about the quantity of published items, some general points can be made. In this article, such data will be taken as starting points for a general look at non-university research.

Non-university research

Pride of place in non-university research belongs to 'Demokritos', a research centre for fundamental science in Athens. The number of publications attributable to its 40 biological researchers equals the number attributable to equivalent researchers in Athens University; and its 140 researchers in physics and chemistry produce more publications than their university colleagues.

Scientists at Demokritos are, of course, free from teaching commitments; but so are scientists at other less effective institutes. The factors contributing to Demokritos' success seem to be the lack of the narrow compartmentalisation of the university, the relative independence of scientists in planning their research and competing for project grants, the higher qualifications possessed by practically all scientific staff, and good facilities.

In addition to fundamental research, the centre tackles some practical tasks. These include the production of 130,000 μCi of short-lived radio-isotopes (another 35,000 are imported) for hospital use (the centre was in fact founded around the reactor and still carries the name 'nuclear research centre'); dealing with methods for searching for uranium deposits; main-

taining a human tissue bank for transplants; and doing fundamental work on photosynthesis with the use, for biological control, of sterilised males of the insect pest of the olive, *Dacus oleae*. Demokritos would probably be a good place for postgraduate students to work.

The papers from 'other centres' come from a variety of establishments, including the National Research Foundation (with 30 publications) industrial laboratories and so on. For convenience, publications from the small, young universities of Yannina and Patras are included in this category.

Medical research

The medical faculty of the University of Athens has recently produced, with some pride, a list of 5,859 publications by its members in 1970-75. The press, however, soon pointed out that of these, the bulk are locally published articles, case discussions and so on. Only 757 are refereed papers in international journals; and some of those cover work carried out abroad. The *Science Citation Index* figure of 479 (see table) is limited to the years 1974-77 and does not seem to contradict this figure.

It cannot be disputed, however, that hospital doctors come across ample case material, and have sufficient facilities for doing clinical tests, leading to publishable observations; the stimulus, and in fact competition, for publishing such observations is undoubtedly strong. But few papers deal with biomedical, as distinct from clinical, research. Some medical research teams have become internationally known for a continuing body of work in certain fields, such as the

locally important problems of haemoglobinopathies and of enzyme polymorphisms.

But the prestige of the Athens medical faculty is not founded only on the number of papers it produces, but also on the social impact of the medical profession. Has the profession been able to provide adequate medical cover for the population? Is the standard of medical care much higher in the lucrative private sector than in the public sector? Is the profession avoiding the worst excesses of private practice?

These are legitimate questions when thousands of patients travel every year to seek treatment abroad, especially as they cannot help but compare the ethical attitudes and fees in other countries with those back home. It would also be interesting to find out whether the lucrative character of private medicine in Greece—or more accurately, of a special circuit of private medicine including a high proportion of university professors—will attract to Athens, when Greece enters the European Economic Community many doctors from other member countries.

Agricultural research

Another sector where social impact is important is agricultural research. The achievements of numerous stations and institutes run by the Ministry of Agriculture are not adequately reflected in the table because much of their work ends in filing cabinets, or is translated into circulars; and work lasting ten or more years to establish a new variety of wheat may yield very few papers.

But it may yield a lot of grain. In the 1920s when one and a half million refugees, mainly from Ionia, arrived in Greece destitute, the average wheat yield was 220 kg per acre. The late Papadakis, a dedicated agriculturist, started work at a small station in Thessaly with the aim of breeding new varieties better adapted to the country. It is largely thanks to the breeding work he initiated that, today, Greece

Numbers of papers listed in the Science Citation Index 1974-77 as originating from Greece.

Dr E. M. Pantelouris visited Greece as a Nature travelling fellow

is self-sufficient in wheat, with an average yield of 1,000 kg per acre, and could, if it were economical, produce some wheat for export. Greece might in fact do that specifically for the hard wheat required by EEC industries.

From that Cereal Improvement Station of Thessaly has developed the Cereal Breeding Institute of today at Thessaloniki; and the country has also become self-sufficient in barley for animal feed, and in rice. Corn is a problem, mainly because in the Greek climate it requires irrigation, and the country has very little irrigated land. All the work on cereals is carried out by about 20 members of staff at the institute, with the help of other people at peripheral testing centres. This is cost-effective research.

The same can be said about other research stations dealing either with single crops (such as cotton, in which again self-sufficiency was achieved years ago) or with livestock. The Yanitsa Livestock Improvement Station has had successes of great potential with crosses of the local Chios strain of sheep with Friesland sheep.

There are also some larger, interdisciplinary, institutes. The Benaki Phytopathological Institute near Athens deals mainly with entomology. Although founded in 1929 as an independent establishment, it is now largely supported by the Ministry of Agriculture. It deals with problems such as the notorious *Phylloxera*, which is reappearing in the vineyards of Crete, and the biological control of citrus-fruit scale insects.

The two forest institutes, at Athens and Thessaloniki, are also multidisciplinary. Forests in Greece are largely state owned, and are run by a system where the forestry service supervises all operations in co-operation with local villagers on contract. The institutes therefore have a variety of concerns, ranging from timber technology, mechanisation, and the introduction of new economic plantations, such as poplar and eucalyptus, to the protection of forests from fires, which caused enormous damage last summer. The forest institutes could perhaps concentrate more on forest and soil preservation in the least productive and uneconomic areas.

The work of these stations and centres suggests that small research groups, geographic isolation, and restricted facilities are not necessarily disadvantages so far as applied research of this type is concerned. Success hinges more on leadership and dedication. Applied research may well benefit more generally from the work of small task-oriented groups. Fundamental research on the other hand would be

Karamanlis: implementing a new science policy

better served in larger, multidisciplinary centres.

A New Research Policy

The Greek government is taking measures to stimulate 'relevant' research.

Greek agriculture suffers because of the small acreage per farmer, and can only be uplifted by technological progress and, in the last resort, by conversion to irrigation. Industry has, for some years now, exceeded agriculture in importance. To make both viable within the EEC, and to raise the per capita income, which now hovers around the level of Ireland, the government believe that indigenous activity in the fields of applied R&D is essential.

In general terms, the following policy has been formulated. On-going research will continue to be supported at present levels. New funds, however, will be made available specifically for research related to a few key requirements of the country's development plan. These funds will not be dispensed as support grants for institutions as such, but in the form of grants for specific research projects, submitted by individual or grouped workers. Foreign scientists are not excluded.

A law institutionalising the policy was passed last year and the Prime Minister, Mr Karamanlis, is by all accounts pressing for a speedy implementation. A cabinet committee is in control, and a special civil service department has been set up at the Ministry of Coordination, headed by Dr Argyropoulos, an electronics expert returned from the United States. A census of laboratories has been carried out, but due to lack of cooperation, it is as yet incomplete.

The new policy combines two pragmatic approaches: that of letting work now in progress continue; and of setting up target-oriented research.

One of the potential virtues of the combination is that it might forestall the reappearance of the old pattern in the guise of the new.

Success will now depend on how the policy is implemented. Firstly, an advisory council will be appointed by the government. Its appointment will be crucial because it must be efficient and imaginative, and must inspire complete confidence in the research community. The second crucial task is the definition of a handful of research sectors where efforts will be concentrated. If the definition is too narrow and specific it may inhibit creative processes. If too wide, it may be operationally meaningless, and provide no guidance.

For example, one problem Greece has to face is that of soil erosion. Limestone covers one third of the country, mostly in the form of mountains where the extremely fragile ecosystem has been degraded by destruction of forest and by erosion to the state of sparse maquis vegetation and small pockets of soil between exposed rock. What is not already lost must be preserved and every effort made to recoup as much as possible. This will involve preventing the winter rain from causing destructive floods and damaging agriculture and even dwellings.

Defined in this way, the problem appears to be one of traditional torrent regulation so that the seasonal rain is helped to flow safely away. But the water is a precious asset, and the key to making economically viable the Greek farmer's small acreage must be to conserve the winter rainwater for use in the summer. The problem may now be redefined as one of storing the winter rain in each catchment area. Perhaps it could be channeled to underground cisterns, or at least retained in soil 'sponges' created at the outlet of every torrent and gully. Perhaps chemical films should be used to reduce evaporation from reservoirs and special tubing systems (there is one under study by a Greek plastics firm) might permit the speedy and economic irrigation of crops and trees. Perhaps there might even be physico-chemical methods for producing a thin layer of soil on the limestone surface; and perhaps arid-zone plants should be seeded there to retain and improve the soil so that a future generation might reafforest it.

The definition of priority areas must be comprehensive enough to evoke all approaches which, when combined might lead to a solution—a definition of targets and problems, not just of projects and programmes, yet not vague and platitudinous. The successful implementation of the new policy is bound to be a difficult undertaking. □

AAAS

The expert has no clothes

WASHINGTON is a destroyer of myths. It destroyed Richard Nixon. It is destroying Jimmy Carter. And last week, at the annual meeting of the American Association for the Advancement of Science, it was happily destroying the myth of the expert. In the climate prevailing at the meeting, any of the 5,500 scientists attending who were unconscious of or unconcerned by the political, social, or psychological dimensions of their work were made to feel distinctly uncomfortable. The conclusion: scientists must absorb, welcome, and understand politics if they are to retain a niche in the ecology of the latter quarter of the 20th century, and not attempt to ignore or deflect politics through the exercise of defensive public relations.

Six sessions addressed such issues: in sociobiology, where the validity of human sociobiology is a political matter as much as a scientific one; in recombinant DNA, where the assessment of risks is still a political issue, complicated now by the introduction of firms such as Genentech Inc. which hopes to produce insulin by the end of the year, and is not controlled by the NIH guidelines (neither are any firms, defence establishments, or the CIA); in the protection of 'whistleblowers'—people who, like Dr Thomas Mancuso, working for a government agency, call the wrath of the system upon them by claiming a danger exists that the agency management would prefer to ignore (Mancuso claimed that workers in the Hanford nuclear plant, Washington State, were subject to a 5% increased cancer risk, and was taken off the study); in the reception of unconventional science, where people with wild but possibly fruitful ideas receive short shrift from the scientific establishment without much evidence of proper assessment; and in the reproducibility of experiments, where, for example, in one double blind test 70% of experimenters were found to smile at female subjects in a psychological experiment while only 12% smiled at males, thus influencing conclusions on sex role differences.

All these topics involve controversial science, in the sense that it is science at the time of formation, where conclusions are contestable and political and other prejudices can influence the interpretation of results. At this point science is inseparable from politics, and the Washington meeting went a long way to showing why and how this was so case by case. The sessions

chipped at the armour of the expert who set him or herself up as the final arbiter of truth, letting the politics go hang, and showed his and her relativity to social context wherever the science was ambiguous.

In recombinant DNA, for example, one commentator (Dr Susan Wright of the University of Michigan) concluded that "claims that the available evidence points in one direction or another seem premature. The view that the risks are minimal should be taken as the tentative opinion of a relatively small sector of the scientific community rather than a well established, theoretical position." Dr Philip Handler, President of the National Academy of Sciences, during a rather protectionist speech, spoke of "a crescendo of concern which is now diminishing somewhat. The public was frightened by tales of imaginary hazards reminiscent of the *Andromeda Strain* (a book written to be entertaining, not believed). And the statements of a handful of scientists, few of whom were close to this field of research, were taken as evidence that 'the scientific community is itself divided'".

In human sociobiology, Dr Edward O. Wilson, of Harvard University, believed he was articulating firm scientific evidence for the genetic basis of human behaviour, while one of his critics, Dr Stephen Gould, also of Harvard, argued that Wilson was doing no more than telling 'just-so' stories and not accumulating truth at all.

In the study of low level radiation effects as a cure for cancer among Hanford workers, Drs Thomas Mancuso, Alice Stewart, and George Kneale believed their results, though based on a quite small number of cases, to be of great human significance, while other scientists associated with earlier (and ten times smaller) estimates of radiative danger (principally from studies of the survivors of Hiroshima and Nagasaki) tended to dismiss the new data as alarmist.

Handler expressed the wish that "those engaged in such research would behave as scientists generally do and refrain from publication until they have completed a sufficient series of coherent studies to enable rational decision, rather than announcing each experiment in turn, generating public alarm that can neither be justified or assuaged". But such a view would seem to be idealist when the public want and need to know about possible dangers

as early as possible.

Handler quoted Maurice Arthus, one of the founders of immunology, who warned that when one had a dogmatic attachment to a theory "to persist in one's faith becomes in a sense a question of honour. Having adopted such a public position the protagonist . . . becomes like the attorney who defends a client in spite of the evidence of his crime. . . ." Handler added "how reminiscent of the recent history of DDT, diethylstilbestrol, cyclamates, and the SANGUINE antenna". Those of a different political persuasion might like to add others to Handler's list.

The most strident critic of the ivory tower was representative Richard L. Ottinger, member of the House Committee on Science and Technology, who spoke in a session on recombinant DNA. "DNA research has given me a fascinating insight into the arrogance and anti-democratic spirit of which the 'established' scientific community . . . has shown itself capable. Those who lobbied so hard to prevent the Congress from taking steps many of us are convinced need to be taken to protect public health and safety have shown that they think themselves omniscient and infallible. 'We are the experts' the saying goes, 'and you can't possibly understand whereof you speak'. I resent that, and I resent it extremely, and the American public will destroy you if you take that attitude".

Further, Ottinger claimed that scientists were not apolitical at all, but in fact rather vicious in dealing with their recalcitrant colleagues. Handler spoke of the "bitter irony that . . . the protest movement appears to be growing significantly from within science itself. These voices may comprise a very small fraction of the scientific community, but the malaise is real". This sounds dangerously like what Ottinger describes as "suggestions that have been made that scientists who themselves urge constraints may be alienated from the main stream. We have seen this happen, again, in the nuclear debate, and I sincerely hope that, this time, researchers into the problems and hazards of DNA will not find their research stifled". Ottinger added: "If I disagree on a policy matter with another member of the House, I'll tell him, and then I'll do my utmost to defeat his position. What I won't do is vilify or threaten him. Academic politics, on the other hand, is a reality too many attempt to avoid recognising."

Robert Walgate

AAAS

Race and IQ: Jensen retains fellowship

A MOVE to retract the fellowship awarded last year to the psychiatrist Dr Arthur R. Jensen was defeated at a council meeting of the American Association for the Advancement of Science last week. Jensen has long claimed that there is a heritable IQ difference between blacks and whites. His critics argue that his conclusions are based on a false interpretation of the data—and, in part, on false data—and accuse him of racialism.

The International Committee Against Racism (INCAR) petitioned the council on 16 February for 35 minutes, presenting six witnesses including three blacks: a disabled veteran, a Chicago construction worker, and a University of Denver neurophysiologist. The plea, in no uncertain terms, was that Jensen's arguments were non-scientific, in the tradition of white racialism, and unworthy of the AAAS. Jensen must be expelled, INCAR demanded.

INCAR, however, had no formal status at the meeting, and their motion was never put before the council. There were good reasons for this. Jensen was not present to defend his case. A decision to remove him would probably be unconstitutional under AAAS rules and the council was not as a body specifically competent in either psychology or genetics, opening it to the charge of acting on political and not scientific grounds. (Jensen's nomination had been presented last year by what should be a scientifically competent body, the psychology section of the AAAS).

The one black member of council present, Dr Bernard Gifford of the

Russell Sage Foundation, argued that for these reasons the council could not reject Jensen. But it could, he argued, reinvestigate his work, for since his nomination it had become clear that the twin studies of Sir Cyril Burt, on which a large part of Jensen's conclusions was based, were fraudulent.

Jensen's principal supporter at the meeting, Dr Lloyd Humphreys, a psychologist of the University of Illinois, attempted to outflank this move by claiming that Jensen's controversial work was only a small part of the evidence presented on his behalf to the psychology section last year. That caused a hiccup in proceedings until Gifford called for the citation which went with the Jensen nomination to be read out. It read: "For his research on testing individual differences, and intelligence: and particularly for features of his studies of intelligence testing". Gasps throughout the room.

Jensen likes to popularise his work. He wrote, for example, in the *New York Times Magazine* (31 August 1969): "There are intelligence genes, which are found in populations in different proportions, somewhat like the distribution of blood types. The number of intelligence genes seems to be lower, overall, in the black population than in the white". Yet according to Dr Stephen Gould of the Museum of Comparative Zoology, Harvard University, "Stephen Gould of the Museum of Comparative Zoology, Harvard, Jensen's conclusion is based on weak data and contains a fundamental fallacy."

Gould, a AAAS council member, told the meeting that "if you subtract

Disabled black veteran petitions AAAS council

the Burt data from Jensen's material you subtract the only controlled experiment . . . There is much debate on the rest". Further, he argued that while he accepts the existence of a 15-point IQ difference—one standard deviation—in the mean IQ of the black and white populations of America, this does not mean that the difference is genetic, even if the IQ is heritable within the black and white populations. "To assume so is a basic fallacy", said Gould. "I deal with this in the first lecture of my course on genetics".

The distinction is between 'within group' and 'without group' heritability. Height, for example, has a high heritability. The height of children is well correlated with the height of their parents. There is therefore a genetic factor at work. However, if one inbreeding group has a smaller height than another it does not mean they have "fewer height genes". It may well mean that the former group has a poorer diet than the latter. So with IQ: environmental factors cannot be eliminated even if within-group heritability is demonstrated.

In spite of such arguments, which were supported among others by Dr Mary Gonzales, the Vice-Chancellor of the University of Maryland, who has the problem 'on her doorstep', the only motion passed by the council was an anodyne prescription claiming that the AAAS has never adopted and never will adopt a racist or otherwise discriminatory stance. Dr Gifford, the black member, disputed the motion: AAAS involvement in the eugenics movement of the 1920s and 1930s made the motion a whitewash, he said.

The last chance for movement on the Jensen issue came with a motion to examine "the credibility of the scien-

No more fellows of the AAAS?

IN A move not entirely unrelated to the Jensen case, the AAAS council last week voted to impose a moratorium on all further fellowship elections, and to conduct a straw poll of the membership to determine if it wants to keep the institution. "It would be an act of grace and mercy to kill the fellowship scheme," said Dr Robert Allen, chairman of this year's Fellowship Committee. The AAAS has 128,000 members, (16,000 of them are fellows), but the process of electing new fellows is becoming a nightmare—and not just because of controversial elections.

Several of the sections of the AAAS fail to submit nominations at all, said Allen. This year seven of the

21 failed to do so, and only seven filled their quota. The evidence presented by the candidates on their behalf is meagre, and in the day the committee allots to selection there is time for only two minutes consideration of each candidate. No more time is spent as there is usually insufficient evidence to justify it.

The council will only use a poll of membership as a guide. If the members vote to abandon the fellowship, then a lengthy procedure has to be set up to change the constitution. If they vote, as expected, to keep it, the council will have to consider very carefully how to improve the election scheme to make it more equitable and less open to criticism.

tific work of Dr Arthur Jensen and its pertinence to the award of a fellowship to him". Gould called the motion "a somewhat abated formulation but probably the best we can do". Dr William Carey, Executive Officer of the AAAS, argued against it on the ground that if it were adopted he saw no end to the issue. That incensed one member, Dr James Silverberg, an anthropologist, who said "the reason we are spending so much time on this is that we left Denver [the location of the last annual meeting] with egg all over our faces". Silverberg condemned the earlier general motion as "a totally hypocritical statement. We have evidence that we knew what we were doing" and threatened to resign his own fellowship if the motion to reinvestigate Jensen did not pass. The motion failed by 25 votes to 10, a larger margin than the original vote last year to elect Jensen (28 votes to 24).

After the meeting, Gould expressed no surprise that the vote had gone the way it did. "The typical council member is an organisation man" said Gould. Gifford, on the other hand, was more disappointed. Humphreys had supported the investigation, retaining his belief in Jensen, and it had seemed to Gifford at that point as if the vote might go for the inquiry. Gifford is now believed to be planning to set up an *ad hoc* investigation of Jensen's work outside the auspices of the AAAS. He also believes the seeds of another Jensen affair may have already been sown with the election to fellowship this year of Dr Robert W. Fogel, author of the book, *The Economics of American Negro Slavery*. The book argues that the Negro slave was better off and happier than is usually thought. "Fogel is a friend of mine" said Gifford "but this book doesn't represent his best work".

Robert Walgate

Special treatment for Cuba and Mongolia

CUBA and Mongolia are to receive preferential treatment as 'less-developed' countries, under the Comecon plans for scientific and technical cooperation. This was announced by the Cuban Deputy Premier, Belarmino Castella Mas, in his opening speech at the eighteenth session of the Committee for Scientific and Technical Cooperation; the first meeting of this committee to be held in Cuba.

Comecon cooperation in science and technology, as in all other branches of the economy, is officially governed by the 'Complex Programme of Further Intensification and Perfection of the Cooperation and the Development of Socialist Economic Integration among the Comecon countries' of 1971.

This laid down long-term objectives (up to 1990), including the formation of international scientific and technical associations, joint laboratories, coordination centres, scientific and technical councils and study groups.

The programme, however, seems to have proved too grandiose in practice so the January 1976 meeting of the Committee on Scientific and Technical Cooperation stated that for the present, scientific cooperation will be largely devoted to research projects "which cannot be solved by individual countries".

The recent session of the Committee had as the main item on its agenda the accelerated development of science and technology in Cuba. Comecon planning policy tends to follow current Soviet doctrine; hence the current emphasis is on practical applications rather than basic research. Development programmes will include the increased use of modern technology in the cultivation and processing of sugar cane, 'agro-industrial' development of citrus fruit production, the use of nuclear energy (a power station is to be built in Cuba by the Soviet Union), solar energy, and the development of the electrical power system. Plans to increase Cuban nickel and cobalt production to 130,000 tonnes per year (almost a quarter of the total world nickel output) have already been under way for a year.

Details of the financing of these projects are not available. Rather remarkably there is no central Come-

con fund for financing joint research projects, and all cooperation projects have to be based on *ad hoc* financial agreements between the member countries concerned. It is noteworthy, however, that while Eastern Europe has a considerable beet sugar industry, there seems to be an upper limit to further expansion—increased use of fertiliser providing larger gross tonnage of beets but no larger yield of sugar.

Investment in the Cuban sugar industry, whether or not repaid directly in kind, is likely to benefit the flagging food industry of Eastern Europe. And the development of Cuban nickel will provide a much-needed component of high-quality steels and high-strength nonferrous alloys.

To date, Cuba's contribution to Comecon has consisted largely in hosting meetings of the Executive Council and various committees, provision of a site for a satellite-tracking base, and the export of certain commodities (some of which, like cigars, are considered by the senior partners as "inferior"). Likewise, Mongolia's main contribution has been in geological surveys which will ultimately provide raw materials for the bloc.

The new "preferential treatment" of Cuba and Mongolia while undoubtedly beneficial to the development of their economies, still seems ultimately directed at the over-all good of Comecon *in toto*. The plans for the 'less developed' members clearly reflect the ultimate aim of an integrated economy.

Vera Rich

Denmark follows UK on DNA guidelines

DENMARK is preparing guidelines for research involving genetic engineering. At the end of last year, the Danish Parliament offered broad approval to the recommendations laid out in a report of the 'Registration Committee for Genetic Engineering' and assigned to the Committee the task of working out preliminary guidelines for experiments involving recombinant DNA.

The Committee was set up by the Danish Research Councils in July 1976 on lines similar to those of committees in other countries. Its task was to formulate proposals for the Commission for Genetic Engineering, a permanent organisation to control genetic engineering in Denmark, and then to function as the Commission pending its establishment. The Committee is made up of representatives from the National Health Service, the Agency for Environmental Protection, the pharmaceutical industry and the Ministry of the Interior.

To find out where genetic engineer-

ing research is done in Denmark, the Committee inquired into 195 public and private laboratories and organisations and found that no such research has yet been done. Two laboratories, however (one of them the Carlsberg Laboratory), intend to do experiments involving genetic engineering very soon.

Many of the report's recommendations are in line with those of the UK Williams report rather than the US NIH guidelines. This suggests that the Committee has taken into account the wish of the European Science Foundation (ESF) and the European Molecular Biology Organisation (EMBO), that regulations should be equivalent, if possible, in all European countries.

As Denmark has only very limited resources for building high containment laboratories, Danish scientists will probably carry out high-risk experiments in common European laboratories (for example, the EMBO laboratory under construction in Heidelberg). It is therefore important that they

should be subject to the same regulations as those operating in such international laboratories. The Committee also feels that if Denmark sticks to common guidelines, it will be able to call on experts in the ESF's 'Liaison committee on recombinant DNA research'—on which it is represented—for advice with specific genetic engineering problems.

The report's recommendations aim at controlling public as well as private research and ensuring that the community has the power to regulate the use of any results from genetic engineering research which may pose hazards to the environment, animals or man. And that power, the report says, should eventually be vested in the Commission for Genetic Engineering when it is set up.

All research and production using genetic engineering will then have to be made known to the Commission and particularly hazardous procedures will not be allowed to go ahead without the Commission's approval. Laboratories will have to be approved by the Directorate of Labour Inspection, or by a public or private institution authorised by the Directorate in collaboration with the Commission. People working with genetic engineering will have to be adequately trained; accurate records will have to be kept of all experiments; accidents will have to be immediately notified to the Commission and laboratories will have to be inspected regularly.

A point which the Registration Committee suggests should be looked into further is the question of whether existing Danish law (the Epidemics Act 1915, the Working Environment Act 1975, the Environment Protection Act 1973) affords a sufficient supervisory authority to inspect laboratories or whether special legislation will be needed. Eventually, however, recommendations from the European Economic Community (EEC) will have to be taken into account on the latter point. As yet no decision has been taken on which central authority the Commission should be placed under, but the Registration Committee suggests that the National Health Service, which supervises other forms of microbiological research, might be the most suitable.

The Registration Committee's next task will be to collaborate with the National Health Service, the Directorate of Labour Inspection and the Agency of Environmental Protection to work out preliminary guidelines for registration, supervision, approval of laboratory facilities and so on. In the meantime it will keep the government and administrative authorities informed of developments abroad.

Sven Godtfredsen

First Ratan results published

THE first results of experiments with Ratan-600, the 600 m radio-telescope of the Soviet Academy of Sciences, have recently been published. The experiments are essentially exploratory and performance trials ranging from solar to extra-galactic observations.

The Ratan-600 represents a new generation of radio-telescopes. Its design parameters are impressive: information capacity 3×10^{12} bits, limiting resolution 2 arc sec, accuracy of definition of coordinates 0.01 sec², limiting flux density 0.01 Jansky, limiting brightness temperature 0.03 K, sky coverage 70–80% with scanning time 100 days. Ultimately it is hoped that Ratan-600 will not only provide direct observational results, but will serve as a basis for experiments estimating the intensity of gravitational waves and confirming general relativity on the basis of the bending of rays in the gravitational field of the sun. Although these sophisticated experiments lie in the future, a number of interesting results have already been obtained.

The high resolution and large collecting area of RATAN-600 permit the observation of solar "pores"—areas of limitingly weak activity which will later develop into sunspots. It also allows the radiogranules, first discovered during the transit of Mercury in 1970 to be monitored in non-eclipse conditions and for several frequencies simultaneously. A programme of joint radio and optical investigation of solar

granules has been initiated and preliminary investigations obtained for their magnetic fields.

Likewise, the high resolution made it possible for RATAN-600 to receive radio-emissions from all four of the "Galilean" satellites of Jupiter, in spite of the intense radio-emission from the planet itself. These observations—in December 1976 and January 1977, gave the first results ever for Io, the closest, and Europa, the nearest, of the four. For Ganymede, Callisto and Europa, the results were consistent with thermal emission only, showing no signs of the intense radiation bands observed for Jupiter itself. For Io, however, the result was "totally unexpected"—radio-emission is several times greater than the expected thermal value. It is claimed that this implies that Io possesses a magnetic field and intense radiation bands.

RATAN-600 is also participating in two joint Soviet-Australian projects, on quasars and on early-type emission line stars. Signals have been received from quasar OQ 172, the most remote object in the universe (red shift 3.54). Its present programme also includes observations of the galactic centre, multi-frequency mapping of radiogalaxies, and the first stages of a sky survey in the centimetre and millimetre ranges, which will take 10 years to complete and should provide a radio equivalent of the Palomar sky survey.

Bangladesh plans nuclear research centre . . .

BANGLADESH Atomic Energy Commission, in its efforts to develop peaceful applications of nuclear physics and technology, has drawn up an extensive plan to establish a nuclear research complex in Bangladesh. It will comprise seventeen nuclear and allied projects. A 259-acre site twenty-five miles north of Dacca is already under development. The laboratories are to be integrated to share facilities and also to create an environment conducive to the formation of interdisciplinary teams among the scientists of the Commission.

Mr H. F. S. Bittencourt, Deputy Director General of the International Atomic Energy Agency, while visiting Bangladesh in connection with the inaugural ceremony of the Institutes of Nuclear Technology, Nuclear Medicine, Electronics, Irradiation and Pest Control, the National Com-

puter Centre, the Institute of Space and Atmospheric Research, and other institutes, expressed his satisfaction over the plans and assured all possible help in matters of providing the Commission with a small nuclear reactor. It is expected that the first phase of the work will be completed by 1982, but Bangladesh still needs a 10 to 20 MW reactor, which the BAEC hopes to get as a donation from some friendly country. Bangladesh, however, is required to obtain a nuclear safeguard clearance before obtaining a nuclear reactor and it is hoped that the IAEA will extend the necessary help.

Two irradiators each of 50,000 Curies for food irradiation and medical projects are to be procured from Canada. The first one which is expected to arrive in June next, will cost about US\$6,000.

M. Kabir

Soviet schools tied closer to technology

THE relationship between science and the needs of the national economy is a matter of constant theoretical discussion among the Soviet planners. So too is the relationship between education and the demands of expanding technological growth. The latest decree of the Central Committee of the CPSU and the Supreme Soviet on the further improvement of secondary education reflects a new concern with these problems.

The current doctrine stresses that science must serve the needs of the national economy—with Brezhnev's famous caveat that "there is nothing more practical than a good theory!". Even interplanetary probes are announced to have been launched "in accordance with the needs of the national economy". During the last few years, several scientific bodies—for example, the Far Eastern Science Centre—have been publicly censured for failing to orientate their research to the immediate needs of production. The closer coordination of research and the needs of industry is a matter of pressing concern, and has led to the establishment of various problem solving institutes closely linked to production enterprises in their areas.

Not surprisingly, therefore, the new decree on education extends the same process to the secondary school level. Referring to the "Leninist" principle of a "single, labouring, polytechnic school", the decree notes that, at present, school-leavers' skills and outlook do not correspond "to the requirements of social production and scientific and technical progress". The decree continues "Many school leavers go out into the world without the necessary preparation for work, without sufficient information about the basic professions of the masses, and they experience difficulties in the transition to working for the national economy".

This stress on preparation for work suggests a return to the Khrushchev era, when parties of school-children, carrying out what was officially described as "labour training" in factory and collective farm, succeeded only in antagonising and disrupting the workers, who grumbled that they were expected to act as unpaid nursemaids, in addition to their official duties. In fact, however, little is being done on these lines. After the fall of Khrushchev, labour training was quietly phased out except in senior classes; the present decree urges only that pupils of the ninth and tenth classes (16 to 18 years old) should have their "labour training" increased from two to four hours per week (within the limits of the timetable) and that this training should correspond to the facilities and

needs of local production. Special emphasis is placed on vocational training, especially for those leaving after the eighth class (Soviet compulsory education was officially extended to ten classes some years ago, and it is interesting that the option of leaving after eight years has still not been completely

Vanya has stolen the exam questions! I'm not sure whether to fail him or give him an 'A'!

phased out).

Shortcomings in syllabuses and textbooks are stressed; in a number of cases, it is said, these are overloaded with "superfluous information and matters of secondary importance". The proposed changes will ensure that courses include the necessary amounts of the rudiments of the sciences with information on the relationship of the subjects studied to the needs of the economy. At the same time, the total work-load of pupils is to be decreased to 24 hours in the first to third classes, rising gradually to 32 hours in the tenth class. Excessive homework is to be eliminated.

Vocational guidance will become the special responsibility of an Interdepartmental Methodological Council of the Ministry of Education, with a "base enterprise (organisation)" attached to every school.

An increase in the direction of young university graduates into school teaching is envisaged; in compensation, however, the title of "People's Teacher of the USSR" has been established for those who distinguish themselves in the field of education.

Finally, and perhaps most important, school children will at last receive free textbooks loaned to them by the school, and special funds are to be allotted to enable the schools to buy the necessary book stocks. □

Japan makes new study of its science

JAPAN'S total R&D expenditures rank as fourth largest in the world, according to the latest figures released by the Japanese government in a white paper on science and technology, but net growth has ceased, once inflation is taken into account. Total expenditures for fiscal 1975 (the last year for which most figures are given) were 2,622 billion yen, roughly equal to \$8.8 billion or £4.0 billion at that time. This figure was about a quarter the expenditures of the United States and one-third those of the Soviet Union for R&D that year, placing Japan just behind West Germany and just ahead of France. Net expenditures were 2.7% higher in 1975 than 1970, but they peaked in 1973.

Expressed as a proportion of the national economy, Japan's R&D expenditures were 2.06% of the gross national income, compared to 4.8% for the Soviet Union and 2.55% for the United States. The most important comparison to other countries, however, involves identifying the source of these funds. Government expenditures account for only about a quarter of the total in Japan, compared to nearly half the total in most other developed countries. A much larger proportion of

research is thus funded by private industry, which profoundly affects the nature of projects undertaken. Corporations, for example, spend more than three times as much on R&D as either universities or research institutes.

As one would expect, this private funding produces a heavy bias in favour of what would be called applied research and development, in the West. However, this tendency is not readily apparent when one first examines the figures of the white paper—theoretically Japan spends 14.2% of its science and technology funds for basic research, compared to 12.9% in the United States and 8.0% in the United Kingdom. A better understanding of this paradox emerges after examination of other government documents to find what sorts of projects are included under the definition of "basic" research. Many of the areas involved, such as materials development, do indeed require investigation for longer periods than one might ordinarily consider reasonable for "applied" research, but a specific commercial application is usually envisaged. Even by their own definition, however, the Japanese are rapidly decreasing the proportion of

funding devoted to basic research.

The distribution of manpower among various sectors parallels the division of funds, with corporations employing substantially more researchers and technicians than both universities and research institutes combined. For the calendar year 1976, total Japanese R&D manpower was 488,000, divided into 53.3% researchers, 16.2% assistant researchers, and 18.3% technicians. If one allows for differences in defining "researcher", the number of scientists and engineers is about half that in the United States and three times that in the United Kingdom.

Since much of the technological underpinning of Japan's most successful industries has been borrowed and adapted from abroad, a recurring theme of recent science policy statements has been the need to improve domestic research so that more in-

novations could be produced in Japan. One indication of progress has been a strong positive shift in Japan's 'balance of patents', with more Japanese applying for patents abroad than foreigners applying for patents in Japan. But a more important figure is the balance of cost between buying and selling rights to technology, and here Japan runs a large and increasing deficit. Using after-tax figures for all enterprises involved in such trade, 1976 receipts were only 20.4% of sales, down from 22.6% the year before. Clearly Japan remains strongly dependent on research conducted in other countries for much of its industrial technology.

Finally, when comparing Japanese research to that of other countries, the question of professional salaries is often brought up, only to degenerate into a welter of contradictory statements. Interviews with the officials of the

Science and Technology Agency who produced the white paper provide the following basis for limited comparison. In 1976 a 40-year-old researcher had an average monthly income of 225,538 yen, then equivalent to about \$760, including some overtime. A base annual salary would thus come to \$9,125, but to this must be added a lump-sum "bonus" of nearly six months' wages, bringing the total to \$13,687. Since Japanese income taxes are quite low for this salary range, the researcher's after-tax income would be equivalent to that of an American or European with substantially higher gross wages. But since pensions in Japan are substantially less than those abroad, the researchers would have to set aside more of his income for retirement, which generally comes at a younger age than for his foreign colleagues.

John Douglas

THE dispute about gene-splicing typifies some of the current hostility towards science. There is one important exception: gene-splicing dangers are purely theoretical. Recombinant DNA has never been accused of producing a tumour in the bladder of a rat, or of making a brown pelican lay a soft-shelled egg. Nevertheless, the rank-and-file defenders of the environment respond to the summons of their leaders, and sally forth to do battle with the mysterious shadows of manipulated molecules that could envelop and ruin our 'space-ship Earth'. Three billion years of organic evolution will be like an evening we are told, when the fantastic new life-forms escape from the test-tubes.

Perhaps so. In any case, I have been fascinated by the eagerness with which lawyers, clergy, and lawmakers enter the dispute. It was to be expected that the issue would be seized by bureaucracies for purpose of self-proliferation. There were good precedents. The return of predictably lifeless rocks from the surface of the moon gave rise to a scramble for authority as to who should shield us from the dangers of contamination. The officials in charge of plant quarantine demanded that the samples be tested for wheat-rust spores.

The more successful assaults on technology are based on projected rather than actual hazards. The real catastrophes don't seem to be as interesting. Dams collapse and many people are drowned. These tragedies are soon forgotten, and dams for hydroelectric power continue to be built. Plutonium is a better target; it is new, it is dreadful, and it must be

exorcised—just in case. Cigarettes kill thousands with lung cancer and emphysema, but advertisements in the United States still assail us with

Wandering minstrels

THOMAS H. JUKES

gigantic pictures of nicotine-loving cowboys and liberated women smokers. Currently, the carcinogen of interest at the US Department of Agriculture is bacon, not subsidised tobacco.

The most unusual of all targets is the phantom menace of genetically-engineered organisms; a legislated, institutionalised and regulated figment of the imagination. People who know least about DNA are the most eloquent among those who fear it. They don't quote Jim Watson, who, on the subject of recombinant

DNA, was reported to have said recently: "Science is good for society. We are being attacked by everyone who doesn't have the guts to go ahead. The dangers of this thing are so slight—you might as well worry about being licked by a dog".

He was too late. The molecular biologists did themselves in at Asilomar. After this, it was a foregone conclusion that DNA would be placed under official guidelines. Like a layer of molasses, the non-ebbing tide of regulations has crept over the field of gene-splicing. How can a danger ever become trivial if the livelihood of an echelon of bureaucrats depends on writing rules to cope with it? The officials now need to demonstrate their public zeal.

In *The Mikado*, the Emperor of Japan is angry because there haven't been any executions lately in the town of Titipu. A victim must be found, or, by imperial decree, Titipu will be reduced to the level of a hamlet. So the civic leaders schedule a simulated beheading for a wandering minstrel, Nanki-Poo.

Recently, in Boston, a victim was apparently needed to show that the National Institutes of Health guidelines on gene-splicing were being enforced. The prototypic Nanki-Poo was Charlie Thomas, who had been caught red-handed for filing a document too late. Watson was unkind enough to liken such infractions, when committed knowingly, to "cheating at tiddlywinks", but this particular sin seems to have been inadvertent. Anyway, Boston was saved, and let us hope that, like Nanki-Poo, Thomas will escape from the Lord High Executioner.

NERC support for UK geophysics not adequate

SIR,—“Geophysics is a sub-division of geology”. This comment was made by a representative of the UK Natural Environment Research Council (NERC) at the November Royal Astronomical Society meeting on how NERC supports geophysics in the UK. The comment probably revealed more about NERC's attitude to geophysics than all the numbers rained upon us.

£6 million, or 14% of NERC's annual budget, was spent, we were told, on geophysics. In the three relevant national institutes, the support for geophysics as a percentage of total expenditure is 19% at the Institute of Geological Sciences (IGS), 15% at the Institute of Oceanographic Sciences (IOS) and 35% at the British Antarctic Survey (BAS). Ten per cent of the £6 million was spent on geophysics in universities. Further, NERC supports eight research ships on which geophysics takes approximately 13% of the cost.

So an apparently convincing case can be made that support for geophysics is adequate. Most of the geophysics done in the NERC institutes and ships, however, is survey geophysics. In IGS and BAS it is a powerful tool to help the geologist—this is where the idea that geophysics is part of geology comes from (*Nature* 249, 794, 1974). In IOS, solid earth geophysics is the mapping of the ocean floor. But geophysics is a much bigger subject than surveying the external layers of the earth. Geophysics is about ideas on the nature, origin, and evolution of the Earth and planets, and in this field we have shown that we can be international leaders—but for how long with NERC's present policies?

Take one particular subdiscipline, palaeomagnetism. British scientists have led the way in creating this field which has brought about a revolution in Earth science. At present small groups at five universities are doing innovative work, fully competitive with work abroad, but they are starved of research students, and recently the Research Grants Committee decided that the all important instrument for the next decade's work, the cryogenic magnetometer (£20,000), is to be shared between these centres. In comparison, vast sums of money are awarded whenever NERC's commitment to BAS or research vessels needs justification by university research activities. One may legitimately doubt if such projects would be funded to the extent they are on their fundamental scientific merits, but commitments are made, in the case of the BAS, for political reasons.

Nor is the problem simply at the research grant level. Instead of allotting a number of studentships to departments to distribute to those who show exceptional promise, all members of geo-

science departments are now invited by NERC to put forward projects (described in three or four lines on the appropriate form). In awarding studentships, NERC selects projects thought most suitable for training, although the numerical distribution of studentships among departments follows an unchanging pattern. Thus the training awards committee for the geological sciences tells heads of departments which projects to put their research students on, without, of course, intimate knowledge of the department's research programme or of the prospective supervisors. Quite apart from this objectionable inroad into the independence of university departments to decide what courses are best for their students, the system continually throws up insoluble problems; a student wants to work with A, whose project this year has been turned down; nobody wants to work with B whose project has been approved.

The scheme is wisely not followed by SRC, but it doubtless gives NERC a chance to say in Whitehall that the universities are being guided into more 'relevant' research; indeed Dr Twinn of the council said at the meeting that university support is a 50-50 split between applied and pure. This shows a fundamental misunderstanding of the purpose of university research training; it is the intellectual challenge in a field which is relevant to the suitability of training.

Of the studentships awarded by the Committee, 14% are allotted to geophysics. This is not the right balance between a subject in which exciting developments have occurred and the more traditional field of geology. The Department of Geodesy and Geophysics at Cambridge has for as many years as I can remember been allotted two studentships yearly; so has my own department at Newcastle, which the university decided years ago to build up as a large centre of geophysical research. Many less internationally known geology departments receive three or four studentships and Imperial College Geology Department regularly gets over 12. Thus members of the staff of my department have a very much poorer chance of supervising a research student than they would in these more traditionally minded departments.

But as geophysicists have been only a tiny minority on the research grants committee and only one pure geophysicist sits on the training awards committee (no geophysicist has been chairman of either) and as this pattern and the policy are self-perpetuating and NERC headquarters seems entirely satisfied, no change is likely without open debate. In the National Science Foundation's solid earth division the support for geophysics, geochemistry and “traditional geology” is in the ratio of 2:2:1 respectively.

Yours faithfully,
S. K. RUNCORN

Tidal power schemes in Korea

SIR,—While we debate tidal energy schemes in Britain, the Korean government intends to have a tidal power station in operation in Korea by 1986. The group responsible for this is the Marine Science division of the Korean Research Institute for Ship and Ocean, previously known as KORDI (*Nature*, 254, 551).

The western coast of Korea is heavily indented with many large inlets. There are numerous off-shore islands and a tidal range of up to 10m. The country is mountainous with limited fossil-fuel resources and with most of its hydro-electric energy developed. It is heavily dependent on imported oil. A nuclear programme is also being implemented.

For tidal energy production there are several promising sites under examination and we recently visited one of these in Chung Nam province. During this visit we observed the construction of the Sap Kyo tidal barrier Asan-Gun. This is the third sea-arm closure to be made in this area since 1972 for land reclamation and water-resources schemes.

The Sap Kyo barrier is to be 3.4km long, built in water depths of up to 18m, though the greater part of its length is in 8-12m depths. The barrier is being constructed from rock, sand and earth-fill placed over a polyester and hessian bottom protection layer which in turn overlies a mean depth of 12m of silt and sand. The maximum tidal range at the site exceeds 10m and the impounded basin area exceeds 20km².

The closure of the sea-arm is being undertaken by Korean contractors, without special construction methods such as cableways or float-in caissons, although the closure velocities will rise to 8 ms⁻¹. The closure will be made next April, only 17 months after the start of the construction. Time for completion of the whole project, which includes a 12m wide roadway at 8.5m above mean sea level and a sluicing structure 137m long with six shell roller gates, is three years, at a cost of less than US \$30million.

The cost of this embankment is about US \$9,000 per m built at a rate of 3.1 m per day overall*. These are, of course, only approximate measures of performance, but they may be compared with recent estimates made for the Severn estuary closure-barrier of about US \$300,000 per m built at a rate of 2.1 m per day overall. The two schemes are not, of course, strictly comparable as the Severn closure-barrier has many concrete caissons incorporated in it. Nevertheless, if the Lavernock Point-Flat Holm section alone is considered, where the projects are roughly similar, the ratio of costs is still almost 6:1.

Yours faithfully,
F. GRAY

Embryonic and regenerating patterns

from Jonathan Cooke

If the productivity of a scientific model may be judged from the energy with which workers subsequently attempt to refute it experimentally, the recent 'clockface' model of French, Bryant and Bryant for the control of pattern in a variety of developing animal structures (*Science* 193, 969; 1976) must rate as highly successful. Equally characteristic, for a highly charismatic model, is the way in which its proponents refuse to accept at face value the counter-evidence offered by others, and attempt instead to preserve the original concept intact in essence, by tinkering with it in relatively superficial ways. This is as it should be, as it provokes (not to say irritates) the community into yet more experimental work.

The model was proposed as a way of understanding the formation of pattern elements during the regeneration of a range of animal structures including already formed insect and then vertebrate (newt) limbs. There seemed to be a single set of rules governing the kinds of structure produced after simple amputation or various cutting and splicing operations, whether on the leg of a cockroach, the forelimb of an amphibian, or the imaginal disc of a *Drosophila* larva (see also Bryant & Iten, *Develop. Biol.* 50, 212; 1976).

Briefly, the proximo-distal and circumferential dimensions of the limb pattern are believed to be specified by a system of radial coordinates on which the cells are assigned positional values determining which differentiated structure they will form.

Each small region has a circumferential value (numbered arbitrarily one to twelve, hence 'clockface') and a radial, or proximo-distal value. In insect appendages, the surface concerned is literally the cylindrical sur-

face of epidermis whose cells lay down the pattern elements (bristles, cuticle types, and so on) that can be recognised, while in vertebrate limbs it seems to be the cylinder of mesenchyme (and not the skeletal core or the dermal surface) that embodies the position values. For both limb systems the radial co-ordinates run from base to tip of the appendage (proximal to distal), converging at the latter.

Two rules are postulated for the generation of new pattern parts after the removal of tissue or the artificial bringing together of tissue with different positional values. The first is that of intercalation. When tissues of different co-ordinate values are brought together, growth occurs at the junction to lay down tissue of all the intervening values in series, as defined by the shortest route around the arbitrarily numbered clockface and by any missing radial (proximo-distal) levels. But the second rule is that if the radial series is left incomplete distally (rather than simply having a gap in it wherein intercalary growth can occur), the regenerative growth to re-complete the series will only occur if cells including the entire circumferential (clockface) set of values can be present at the healed wound.

It is this second complete circle rule which has been the recent subject of experimental attack, but it is worth asking first why such a hypothesis has so excited and/or irritated those re-searching into the unknown mechanisms of pattern formation. It challenges the idea (which was beginning to gain the status of 'knowledge') that cell position is always coded by some kind of gradient. The shortest-route intercalation rule, applying as it does anywhere around the clockface seems to negate the gradient idea since a 'cliff' or singularity, with special behaviour in grafting operations, would be required at the junction of a graded scalar series of values within the cylindrical tissue.

Bryant and Iten, in the paper cited

above, use the complete circle rule to account, in an undeniably impressive way, for the asymmetry, position and orientation of supernumerary limbs that grow near the graft-host junction when well formed regeneration blastemas are transposed from previously amputated limbs to other, host limb stumps in newts, so as to cause graft-host discordance with respect to anteroposterior axis only, dorsoventral axis only, or both axes (by 180° rotation of blastema on its own stump). Detailed rationale and diagrammatic explanation of the results, according to the model, can be forced in Bryant and Iten 1976, or in Bryant (*Symp. Soc. Devel. Biol.* 3 (ed. Ede, Hinchcliffe & Balls), Cambridge University Press, 1977). Briefly, each supernumerary is seen as a new onset of growth, producing all distal tissues, provoked where adjacent intercalations in opposite directions round the 0-12 series generate new, additional clockface sets of cells at graft-host junction. The finding that there are only two sites for supernumeraries, instead of the formally expected four after a 180° blastema rotation, is accounted for by postulating uneven distribution of the 0-12 series of values in real tissue space round the limb. Why not? Robust models should easily digest such small doses of *ad hoc*ery, as this one does.

Digestion fails however (at least, mine does), at the recent discrepant results reported by Bryant (*Nature* 261, 44; 1976) and now Slack and Savage (*Nature*, 271, 760; 1978), following what seem to be similar experimental tests of the model. Just how similar are the two experiments? Bryant prepared, surgically, compound differentiated limbs composed of two posterior halves and possessing, on the model, two similar partial sets of clockface values healed in mirror image symmetry. The observed failure of regeneration, after amputation of such limbs, was as predicted from the model: no possibility of generating

Jonathan Cooke is a staff member of the Division of Developmental Biology, National Institute for Medical Research, Mill Hill, London NW7.

complete clockfaces, so no new distal tissue production. But the double posterior limbs discussed by Slack and Savage were produced not by surgery in the adult, but by operations in the embryo that altered the antero-posterior polarity of the limb-forming tissues. It is known (see Slack, *J. Embryol. exp. Morph.* **39**, 151; 1977) that flank tissue specifies the polarity of the developing forelimb, and by transplanting a strip of flank to the anterior margin of the limb-forming tissue they can produce symmetrical double-posterior limbs. Such limbs

would have to possess, on the model, partial, mirror-image duplicated sets of positional values; yet on amputation they frequently regenerate a double-posterior pattern similar to that of their initial development. This is in clear contravention of the complete circle rule.

French *et al.* do suggest, in the initial *Science* paper, how the apparent evidence that organ rudiments are successively polarised in two Cartesian-type axes during early development (see the above Slack articles and for example Harrison, *J. exp. Zool.* **32**, 1;

1921), may be reconciled with later regeneration behaviour of limbs initially developing mirror image symmetry in embryonic life, and indeed the possibility of stable initial development of such limbs at all, remains a severe challenge to the clockface model. Perhaps we should not expect to understand, in one breath as it were, the initial genesis of patterns in growing fields in embryos and then their later capacities in regeneration (if they show such capacities, which of course the limbs of higher vertebrates do not). □

Ubiquitous neuronal peptides

from John Hughes and Leslie Iversen

The 1978 Winterschool of the European Training Programme in Brain and Behaviour Research was held on January 8-14, at Zuoz, Switzerland on the topic 'Neuronal Peptides'. The Chairman was J. J. Dreifuss, Geneva.

DURING the symposium, participants attempted to come to terms with the avalanche of new data that threatens to overwhelm those involved in this field. At the latest count, at least 20 peptides are known in mammalian brain with distributions and properties compatible with neurotransmitter functions.

The widespread and often unexpected distribution of neuronal peptides has been demonstrated recently in several laboratories. F. Vandesande (University of Ghent) illustrated the powerful resolution available with immunohistochemical staining techniques. By using carefully purified antisera it is possible to stain selectively hypothalamic neurones containing the closely-related pituitary peptides oxytocin and vasopressin. Furthermore, some vasopressin neurones seem to exist within extrahypothalamic areas of brain. Similarly, B. Flerko (Pécs) described the existence of the hypothalamic releasing hormone LHRH in neurones in various extrahypothalamic areas, and M. Palkovits (Budapest) provided radioimmunoassay results from microdissected brain regions supporting the existence of this and other hypothalamic releasing hormones outside the hypothalamus. Unpublished results of Lundberg and Hökfelt (University of Stockholm) indicate the presence of nerve fibres in the cervical vagus containing substance P, en-

kephalins, gastrin, somatostatin and vasoactive intestinal peptide (VIP). The nodose ganglion contains VIP and somatostatin-containing cell bodies and these together with substance P cells presumably form part of an afferent system, whereas enkephalin and gastrin seem to be contained in efferent fibres originating from cells within the brain. Equally intriguing is the possible coexistence of somatostatin and noradrenaline in some sympathetic ganglion cells (Hökfelt *et al. Proc. natn. Acad. Sci. U.S.A.*, **74**, 3587; 1977). The coexistence of more than one putative transmitter within a neurone clearly has important implications for generally accepted concepts regarding the release and action of neurotransmitters.

J. Hughes (Imperial College, London) described studies on the biosynthesis of the enkephalins, suggesting the need for ribosomal synthesis and the probable existence of a larger polypeptide precursor. There is evidence that a single large polypeptide may represent the common precursor for ACTH and β -lipotropin in the pituitary, and the latter peptide can in turn give rise to α -MSH and β -endorphin. There are other examples of families of peptides originating from a common precursor. Thus, radioimmunoassay results suggest the presence of both cholecystokinin (CCK) and its carboxy terminal octapeptide (CCK-8) in the brain (Dockray *Nature* **262**, 92; 1976; Muller *et al., Proc. natn. Acad. Sci. U.S.A.*, **74**, 3035; 1977). The cerebral cortex is particularly rich in these peptides, which is of interest since this area is relatively sparsely innervated by other known peptidergic systems. Gastrin and CCK probably share a common evolutionary precursor (Larsson & Rehfeld *Nature*, **269**, 335; 1977) and it is not surprising that gastrin-like immunoreactivity has also been reported in brain (Vanderhaegen *et al. Nature*, **257**, 604; 1975).

Turning to the possible functions of CNS peptides, J. S. Kelly and L. L. Iversen (MRC Neuropharmacology Unit, Cambridge) discussed the possible involvement of substance P as a primary sensory transmitter involved in the transmission of pain, and the interaction of enkephalin-containing neurones with pain-transmitting mechanisms at the spinal cord and brain stem level as a possible 'gating' mechanism (P. Wall, University College, London). R. F. Schmidt (Kiel) described the various chemical mechanisms involved in activating and sensitising pain fibres in the periphery. A special category of muscle afferents responds to painful stimuli and to pain-inducing chemicals such as 5-hydroxytryptamine or the peptide bradykinin. The action of bradykinin may involve a prostaglandin intermediate, since its effects on pain fibres are blocked by aspirin.

J. Fitzsimmons (University of Cambridge) reviewed the remarkable CNS effects of angiotensin II in eliciting drinking behaviour in most vertebrates. An outstanding question here is whether such effects are normally elicited by the circulating peptide acting on targets in the brain lying outside the blood-brain barrier, or whether an intrinsic CNS renin/angiotensin system is involved. T. B. van Wimersma Griedanus (University of Utrecht) described results obtained with D. de Wied showing that ACTH fragments and particularly vasopressin are able to delay the extinction of learned behaviour in animals. Whether the central actions of vasopressin are related to an intrinsic system of neurones containing this peptide in brain, or whether the pituitary vasopressin system is involved is again unclear.

The Winterschool showed that the field of neuronal peptides remains a rapid growth area; many unanswered questions have been raised by the sudden discovery of this large group of new putative chemical messengers in the brain, and there will certainly be more surprises to come. □

Methanogenic bacteria: a new primary kingdom?

from J. F. Wilkinson

BIOLOGISTS until recently have divided living organisms into two main groups—plants (including bacteria) and animals. The development of the electron microscope made it clear that a more fundamental dichotomy existed in terms of cell structure and the prokaryotic and eukaryotic types of organism were defined. This latter division has been amply confirmed at different levels of cell organisation, but it has usually been considered quite wrongly to represent a fundamental division into two primary phylogenetic groupings—the Prokaryotae and the Eukaryotae. However, it has become clear in recent years that a eukaryotic cell has a composite nature (for example, Stanier *Symp. Soc. gen. Microbiol.* **20**, 1; 1970). It is generally assumed that chloroplasts and mitochondria are descended from a quite different ancestral line from the rest of the eukaryotic cell, which therefore represents the eventual result of an essentially symbiotic relationship between two cell types. Thus it becomes necessary to assume that there may have been at least two ancestral cell types represented by the prokaryote and the cell type that led to the eukaryote; mitochondria and chloroplasts may or may not represent two further cell types.

Can we obtain any information concerning the evolutionary relationships between such ancestral cell types and is it true that all present-day prokaryotes and eukaryotes fall into two basic groupings? To answer these questions, it is necessary to find suitable structures which are common to all living organisms and to compare them. The more conserved such structures are during evolution, the more suitable they are for the purpose. The molecular biologist naturally seeks some defined polymer in which the base sequence can be determined. A good case can be made that the most satisfactory single molecule available for this purpose is rRNA; it is a component of all self-replicating systems including chloroplasts and mitochondria, it is readily isolated and its sequence seems to change only slowly with time allowing the detection of relatedness amongst very distant species (Sogin *et al. J. molec. Evol.* **1**, 173; 1972; Woese *et al. Nature* **254**, 83; 1975; Fox *et al. Int. J. Syst. Bact.* **27**, 44; 1977). In particular, we now have information on 16S (18S) rRNA from a fairly large range of organisms.

Although initial results using this method tended to confirm the dichotomy of living organisms, a major surprise has

arisen from the analysis of a relatively obscure group of organisms—the methane-producing or methanogenic bacteria (Fox *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 4537; 1977). These strictly anaerobic bacteria have in common the ability to produce methane from CO₂ and H₂ and to obtain their energy by means of this pathway. They have proved to be a difficult group of bacteria to obtain in pure culture, but there has been an increase in research into them in recent years spurred on by their possible use in energy conversion from waste organic matter. They have been found to be a fairly diverse group morphologically, comprising both Gram-positive and Gram-negative bacteria. Indeed, they have often been considered as a heterogeneous collection of organisms which happened to have a common metabolic property—the ability to produce methane from CO₂ and H₂. However, a study of 16S rRNA from 10 species available in pure culture has shown that they rather represent a closely-related phylogenetic grouping which is quite distinct from all other bacteria so far analysed in this way. A measure of their distinctiveness is that two very different prokaryotes, the blue-green algae (bacteria) and the enteric bacteria, are much more closely related to each other than either are to the methanogenic bacteria. Further, the methanogens seem no more related to other bacteria than they are to the eukaryotic component represented by 80S ribosomes. Is it too much to suggest that this difference represents two quite distinct ancestral prokaryotic groupings? It may be too early to say definitely in view of our restricted information on methanogens, but there is some further contributory evidence. Quite apart from metabolic factors related to the ability to synthesise methane and their strictly anaerobic existence, methanogens contain no peptidoglycan in their cell wall, the pattern of base modification in their 16S rRNA is, for the most part, different from that in other bacteria and their tRNA lacks the so-called common sequence TΨGC present in all other organisms tested, be they prokaryotes or eukaryotes (quoted in Fox *et al. Proc. natn. Acad. Sci. U.S.A.* **74**, 4537; 1977).

Arising from this work, it has been suggested by Woese and Fox (*Proc. natn. Acad. Sci. U.S.A.* **74**, 5088; 1977) that there are three aboriginal lines of descent represented by three 'urkingdoms' or 'primary kingdoms'.

The methanogenic bacteria.

This group may have developed at an early stage in the evolution of the

Earth when there was an anaerobic atmosphere rich in CO₂ and H₂ (3 to 4 billion years ago) and they may have played a very important part in the transformation of the environment during this period. Consequently, the name suggested for this urkingdom is the archaeobacteria.

All other prokaryotes so far characterised. This group has three major divisions—the blue-green algae (bacteria), the Gram-positive bacteria and the Gram-negative bacteria. This urkingdom is called the eubacteria and it is the kingdom to which the chloroplast progenitor is derived. Unfortunately, no data seem to be available on mitochondrial rRNA. The cytoplasmic component of eukaryotes. This urkingdom, for which the name suggested is the urkaryotes, presumably represents the engulfing species of the composite eukaryotic cell. If it is granted that these are the three major lines of descent and if later evidence supports this view, what is the relationship between these lines of roughly similar levels of organisation? Do they have a common ancestor no longer represented by organisms on this planet? Little is known about the likely age of the eukaryotic cell, but there is some evidence that the prokaryotic cell types have been reasonably stable for at least three billion years (Shopf *Exobiology—Frontiers of Biology* **23**, 16; 1972). If all three urkingdoms did have a common ancestor, represented by a simpler cell structure than the prokaryote, the evolution of this structure into our major cell lines must have occurred within a relatively short time; during this period the structure of substances such as rRNA must have been very much more labile than they have been in the longer period that has followed. It is clear that the recognition of these three lines of descent represents an exciting phase in the history of biology and there remains much to be done in clarifying the position. □

The trouble with kinase crystals

from C. C. F. Blake

A COMMON question asked of X-ray crystallographers is: can you be certain that the structure of a protein in the crystal is the same as that in solution? Although no blanket answer can be given, the indications are that in most cases the crystalline structure is very similar to that in solution. However, as Koshland pointed out many years ago, protein structures are intrinsically finely balanced so that in the presence of ligands different structural states are taken up that are essential for activity.

C. C. F. Blake is a Lecturer in Molecular Biophysics in the University of Oxford.

J. F. Wilkinson is Professor of Microbiology in the University of Edinburgh.

So a more searching question to ask is: can you be certain that in the presence of ligands, the protein in the crystal is free to take up its appropriate structural form? We can be much less sanguine about this question than about the first, and indeed it is becoming clear that in some cases it may be difficult to answer it at all. In the classic example of the oxygenation of deoxyhaemoglobin crystals, the dissolution of the original crystals and their replacement by new crystals of oxyhaemoglobin indicates in this case that the energy of ligand interaction is greater than the lattice energy of the crystals. But the energy balance need not always be this way round, and what happens when the lattice energy predominates is illustrated by some recent observations on kinases.

The ability of kinases to catalyse the transfer of the phosphoryl groups of ATP to their specific substrates with great efficiency, without at the same time phosphorylating water to any significant extent, has always been intriguing. Especially so since the X-ray studies of hexokinase and phosphoglycerate kinase have shown that ATP is bound at fairly exposed sites on the surface of the enzyme. It seems probable that ATPase activity is avoided by the induction of extensive conformational changes by the enzyme's specific substrates that result in a catalytically active enzyme. On this basis it is the inability of water to effect these changes that prevents its participation in the enzymic reaction. Not unexpectedly, then, X-ray studies of substrate binding to kinases have come rather hard up against the problem of the extent to which conformational freedom of a protein molecule is limited by the crystal lattice.

The study of glucose and nucleotide binding to yeast hexokinase by Steitz and his colleagues (*J. biol. Chem.* **252**, 4494; 1977) is a good example of what can happen. Leaving aside for the present nucleotide binding to the inter-subunit allosteric site, and concentrating on binding to the active site, the observations are as follows. Glucose and *o*-toluoylglucosamine bind to hexokinase at the same site in either its monomeric BIII or the dimeric BII crystal forms, producing similar extensive alterations in the protein structure. Nucleotide binding is more complex: the ATP analogue, adenylyl-5'- γ -imidodiphosphate (AMP.PNP) binds only at the allosteric site but not at the active site in the BII crystals, and in the BIII form only AMP, but not ATP, ADP or AMP.PNP, binds in the active site region. Since inhibitors of hexokinase with respect to ATP also bind at the AMP site it seems probable that this is the nucleotide

location in the active site. In addition building ATP into the AMP site places the γ -phosphoryl near the 6-hydroxyl of the bound glucose. In attempting to understand why ATP or its analogue do not bind at this site, Steitz argues that it is probably because it induces further conformational changes that cannot be accommodated by the crystal lattice. Thus by not permitting the conformational changes the crystal forces inhibit ligand binding. As Steitz points out, inability to bind ligands does not necessarily indicate irrelevant or inactive protein structures, but rather crystals unable to accept the conformational changes that the molecule must undergo during its catalytic cycle. A somewhat similar picture is obtained from substrate binding to the homologous yeast and horse muscle phosphoglycerate kinases, except here it is the phosphoglycerate substrates that are difficult to bind.

A more detailed view of essentially the same problem has come from work on adenylate kinase by Schulz and his colleagues (Sachsenheimer & Schulz *J. molec. Biol.* **114**, 23; 1977; Pai *et al. J. molec. Biol.* **114**, 37; 1977). The pig-muscle enzyme crystallises in three forms whose interconversion is pH dependent Form A, from which the enzyme structure was originally deter-

mined, revealed only one of the two expected nucleotide binding sites. However in Form B that has now been solved, the enzyme has undergone a conformational change, probably triggered by the ionisation of a histidine residue that opens a large pocket that represents the second nucleotide binding site. This site is missing in the A form because the reverse conformational change closes off its entrance. Schulz has been able to identify the new site with AMP binding, and the site known from the A form with ATP binding. With the new crystal form the way now seems open to examine the substrate complexes of adenylate kinase and get closer to the catalytic activity.

The significance of these two studies, not only for kinases but for other enzymes as well, is that the usual techniques of diffusing substrates into previously grown native crystals may be inadequate or even misleading if large conformational changes are intrinsic to the enzyme reaction. The growth of crystals of enzyme substrate complexes, by allowing a new crystal lattice to form around the conformationally changed protein rather than putting the two factors into opposition, seems a more appropriate way of defining the structural forms attained during the catalytic cycle. □

Fibroblast surface protein

from R. C. Hughes

A Conference on Fibroblast Surface Protein was held by the New York Academy of Sciences on November 30–December 2, 1977 under the chairmanship of A. Vaheri, E. Ruoslahti and D. Mosher. The proceedings are to be published in the *Annals of the New York Academy of Sciences* in 1978.

THE cold insoluble globulin (Cig), little regarded when it was first isolated from human plasma in the 1940s, has been the subject of an explosive growth of interest in the past few years under its aliases LETS (large external transformation sensitive protein), fibronectin, fibroblast surface antigen, cell surface protein (CSP), 250 K glycoprotein and cell adhesion factor amongst others. In these guises it is ubiquitous at the cell surface and in the extracellular matrix, and the interest arises because of its possible role in malignancy; on transformation LETS largely disappears from the cell surface. Since no agreement on nomenclature resulted from the meeting I shall arbitrarily use

R. C. Hughes is at the National Institute of Medical Research, Mill Hill, London.

LETS to describe the protein associated with the cell in a relatively intimate or fixed state and Cig for the circulating form.

Biochemical characterisation of LETS and Cig show them to be dimeric glycoproteins with carbohydrate content of around 5% and molecular weight of around 450 K; they consist of two equally-sized polypeptide chains linked by several disulphide bonds. The amino acid composition of both proteins in various species is very similar. But there is a striking difference in the solubility of LETS and Cig in urea which remains unexplained, although it may be due to the association of LETS with cell microfilaments.

More direct comparison by peptide mapping of lactoperoxidase-labelled LETS from human, chick and hamster fibroblasts indicates incomplete homology (R. C. Hughes, National Institute for Medical Research Mill Hill) and P. Bornstein and his colleagues (University of Washington, Seattle) have found several differences in the cyanogen bromide fragments of human Cig and human LETS. On reduction Cig produces a subunit that migrated more rapidly on SDS-polyacrylamide gel electrophoresis than those of cellular

LETs, indicating a molecular weight difference of ~10,000–20,000. By contrast, M. Vuento (City of Hope Medical Center, Duarte) finds that human Cig and LETs subunits have very similar molecular weights, and that their tryptic and cyanogen bromide peptide fragments are indistinguishable. Vuento isolated his LETs from spent culture medium and there are indications that in this case the LETs glycoprotein might have been degraded during 'shedding' from the cell surface before isolation. If this is so the differences reported by Bornstein may relate to a piece of LETs polypeptide not present on Cig or on LETs isolated from spent medium.

Whether Cig and LETs represent identical gene products perhaps with some post-translational modifications, for example by limited proteolysis or carbohydrate additions, remains unresolved. Although no hard evidence was presented to the contrary formal proof will require more structural data, particularly peptide sequencing.

Apart from questions of structure the role of Cig in forming pathological 'cryofibrinogen' precipitates was also of interest. Cig and fibrinogen produce complexes which can be precipitated at low temperature by thrombin. Cig and fibrinogen are substrates for plasma transglutaminase—factor XII (D. Mosher, University of Wisconsin, Madison) which stabilises the precipitated complexes. M. Matsuda (Jichi Medical School, Tochigi-Ken) has found low levels of circulating Cig in the disseminated intravascular coagulation syndrome, presumably due to its depletion by complexing with fibrinogen and subsequent fibrinolysis.

Cig and LETs also bind to various forms of collagen and many complex functions are believed to derive from this affinity. Cig and LETs bind poorly to native collagen but much more avidly to heat-denatured collagen (E. Ruoslahti and E. Engvall, City of Hope Medical Center). The binding site is located within a 35-amino acid fragment of the collagen $\alpha_1(1)$ chain (H. Kleinman, National Institute of Dental Research, Bethesda) and seems to be different from that recognised by platelets. Neither Cig nor LETs seems to be required for cell attachment to native collagen (F. Grinnell, University of Texas) which agrees with the results of Ruoslahti and Engvall. *In vitro*, cell attachment and spreading on dishes coated with dried or denatured collagen is enhanced by LETs from several species and by human Cig (E. Pearlstein, New York University Medical Center, and Grinnell). Presumably Cig or LETs promotes adhesion of cells to collagen *in vivo* in areas such as damaged epithelium or possibly in base-

ment membrane, whose collagens are low in triple helical regions.

The association between LETs and collagen *in vivo* is still very unclear. LETs-like antigens have been identified in basement membranes but cellular contamination must be considered as a possible source and its absence in highly purified glomerular kidney membranes (B. A. Bray, Columbia University, New York) may argue for a rather superficial integration into the collagen superstructure. On the other hand, fluorescent-antibody-staining seems to show some correlation between collagen and LETs fibrils in the extracellular matrix and at the cell surface. The pericellular distribution of LETs and collagen is destroyed by trypsin, but LETs distribution is unaffected by collagenase, indicating some independence of collagen and LETs organisation at the cell surface (A. Vaheri, University of Helsinki).

An important site of LETs-enriched pericellular material is at points of cell

contact, even in virus-transformed cells (L. B. Chen, Cold Spring Harbor Laboratory) which in general are poor in surface LETs due to reduced rates of LETs synthesis (K. Yamada, National Institutes of Health, Bethesda). Direct evidence for a role in intercellular adhesion was also described by Yamada who has inhibited attachment of single BHK cells to cell monolayers by relatively high concentrations of dimeric chick LETs. Yamada and R. Hynes (Massachusetts Institute of Technology, Cambridge) described reversion of transformed cells to a more normal well-spread morphology on substrates by exogenous LETs, showing that some transformed cells can utilise LETs if supplied with it. According to Hynes, Cig is two to three times less active than LETs extracted from cells in promoting these effects which perhaps argues for structural differences or alterations in the plasma component and brings us full circle. □

Consciousness and the physical world

from Godfrey Vesey

A conference on Consciousness and the Physical World was held at the University of Cambridge on 9–10, January, 1978. It was organised by B. D. Josephson and V. S. Ramachandran, University of Cambridge.

As a rule scientists leave questions about the mind and its place in nature to philosophers. But there are exceptions to the rule. Some readers of *Nature* (168, 53; 1951) may remember J. C. Eccles suggesting explanations of how 'mind influences' might have an effect on the cerebral cortex. His speculations embraced psychokinesis and ESP. 'If the so-called psi-capacities exist, they provide evidence of slight and irregular effects which are precisely of the nature that must be postulated for brain-mind liaison.' Now there has been a whole conference on this and related issues. How much has changed in the attitude of scientists to these questions in the 27 years since Eccles' paper was published?

In general there is an increasing recognition by scientists of the need to think twice about questions involving 'the mind' before setting about answering them. Grammatically they may look like questions calling for an answer in terms of a postulated causal relationship of some sort. But the grammatical appearance

may be misleading. Some of the key words in which debate about 'the relation of body and mind' is conducted are 'I', 'consciousness' and 'feeling'. It is increasingly recognised that to talk about the meaning of such words may not be to talk about 'things', even things distinguished from the ordinary run of things by being described as 'private'. The first task is that of reaching agreement on what these words mean, how they are actually used; and of dispelling the inapplicable models of their meaning we have inherited from the past.

This general observation may be illustrated with some examples from the Cambridge conference. In his opening remarks H. C. Longuet-Higgins (University of Sussex) spoke of the elusiveness of the concept of consciousness, and stressed the importance of making sure that we used the word 'consciousness' in the same sense. He went on to distinguish several approaches to the concept. In connection with one of them, *via* the theory of observation, he remarked that it may be quite mistaken to regard consciousness as an *explicandum* of the same kind as a commonplace biological function such as feeding or reproduction. In connection with another approach he said something which could be taken as having a direct bearing on Eccles' attempt to discover what it might be about certain cortical states which render them susceptible to 'mind influences'. 'If one rejects the concept of a "homunculus" sitting at the controls of the brain, then

Godfrey Vesey is Professor of Philosophy at the Open University and Director of the Royal Institute of Philosophy.

the physical phenomena associated with consciousness need not be supposed to differ physically from any other observable phenomena.' But for a philosopher perhaps the most interesting thing about his talk was that he refrained from following a certain line of argument. He began a sentence 'When we use the first-person singular we are claiming . . .', then stopped short, and said 'No, let me start that again'. A possible continuation of the sentence he started would be: ' . . . awareness of something, a self, to which the word "I" refers'. Bertrand Russell once argued that we could not understand a sentence beginning with the first person singular pronoun 'unless we were acquainted with something which we call "I"' (Russell, *Problems of Philosophy*, Oxford University Press paperback, 28; 1967). Later he changed his mind, not being able to discover by introspection an 'I' performing an act of thinking (Russell, *Analysis of Mind*, Allen and Unwin, London, 17; 1921). The problem of the meaning of 'I' is one which has continued to exercise Cambridge philosophers. One of the best papers in my judgement is the recent 'The First Person', by G. E. M. Anscombe (In *Mind and Language*, (ed. Guttenplan) Clarendon Press, Oxford, 1975).

A number of speakers tried to find evolutionary explanations of our being conscious. According to H. B. Barlow (University of Cambridge) consciousness is one of nature's tricks to ensure that man is gregarious. In his argument for this conclusion he made a connection between consciousness and the ability to communicate. Roughly, consciousness is a matter of being able to represent things to oneself symbolically, and this ability is logically parasitic on the ability to represent things to others symbolically. A philosopher's reasoning for this might be that the behaviour of language-users is rule-governed, that if someone's behaviour is governed by a rule he must be to some degree conscious of the rule, and that it would not be possible to distinguish between correct and incorrect applications of a rule if there were not a community of language-users (Kenny *et al.* *The Development of Mind*, 94; Edinburgh University Press, 1973). Barlow went out of his way to express his conclusion as paradoxically as possible, by saying, for example, that we only become aware of a sensation when we are prepared to communicate it. Understandably, he encountered some scepticism.

In some respects the thesis of N. K. Humphrey (University of Cambridge) was precisely the opposite. According to Barlow self-awareness is parasitic on other-awareness (or, as he put it, 'the modelling of other people's behaviour is primary'); according to Humphrey other awareness is parasitic on self-awareness. The starting-point of Humphrey's argument was the view that an animal derives

concepts such as pain and hunger from its own internal feelings. A social animal then uses these concepts, acquired by introspection, to understand its fellow animals. This introspective consciousness 'has evolved as a biological adaptation for doing psychology in nature'. I was strongly reminded, by Humphrey's account of how concepts are acquired, of the doctrines of such empiricist philosophers as John Locke, J. S. Mill, Russell and A. J. Ayer. The doctrine that words have meaning by standing for experiences carries with it one of the most intractable problems of philosophy, the so-called 'Other Minds' problem: if 'pain' is a name I once gave to an experience I had, and proceeded to give to later experiences on account of their similarity to the original one, how, without giving it a different meaning, can I use the same word for what is in principle not experienceable by me, something in another mind? In his later works Wittgenstein argued that the empiricist doctrine about meaning is profoundly wrong. Someone who accepted his view and had to choose

between siding with Barlow or with Humphrey would choose to side with Barlow.

Eccles began his 1951 paper by remarking that 'for each of us only our own mind is an observable', and alluding to the argument that the private and restricted nature of the observation eliminates mind from the class of facts of experience upon which scientific investigation may properly operate: it is 'a field outside the matter-energy system of the natural world'. In my own contribution to the Cambridge conference I suggested that our treating people as people rather than as automata is a matter not of our believing them to have private access to supernatural processes but of our accepting some of the things they say, for example about their hopes and expectations, simply because they say them. The difficulty, as Wittgenstein once remarked, 'is not that of finding the solution but rather that of recognising as the solution something that looks as if it were only a preliminary to it' (Wittgenstein, *Zettel*, Blackwell, Oxford, 1967). □

Chromatin transcription probe

from R. S. Gilmour

OVER the past 15 years our ideas about gene regulation in animals have been influenced by observations on the *in vitro* transcription of isolated chromatin. The advent of complementary DNA (cDNA) has facilitated the analysis of chromatin transcripts for gene-specific RNA. However, a major drawback of this system is that endogenous *in-vivo*-made RNA which coisolates with the chromatin can also contaminate the isolated *in vitro* transcript. One method which seemed to offer a solution to this problem was to carry out the transcription in the presence of a mercury-substituted nucleoside triphosphate (usually Hg-UTP) and then to separate the *de novo* synthesised, mercurated RNA from non-mercurated endogenous RNA by affinity chromatography on thiol agarose columns. A number of groups purport to have shown the transcription of a specific gene in isolated chromatin in this way.

Recently, however, the validity of this approach and indeed of *in vitro* chromatin transcription in general has been questioned by new findings. In a recent issue of *Biochemistry* (16, 5135; 1977, see also *Biochem. biophys. Res. Commun.*, 75, 598; 1977), Zasloff and Felsenfeld suggest that the mercuration technique highlights a previously un-

suspected artefact of chromatin transcription. Briefly, these workers isolated *Escherichia coli* RNA polymerase transcripts of duck reticulocyte chromatin by incorporating Hg-UTP and analysed for globin RNA sequences by hybridisation of duck globin cDNA. Surprisingly, however, the synthesis of globin mRNA sequences was not sensitive to levels of actinomycin D which stopped virtually all other RNA synthesis from chromatin. The implication that the polymerase was in fact copying endogenous RNA rather than DNA was strengthened by the finding that when artificial chromatin templates were constructed from *E. coli* DNA and erythrocyte histones and deliberately contaminated with globin mRNA, this RNA was subsequently isolated with the purified mercurated transcripts. It would appear that when the polymerase copies endogenous RNA it forms a hybrid, one strand of which now contains Hg-UTP. The endogenous RNA however accompanies the newly synthesised mercurated RNA through the thiol agarose purification by virtue of its mercurated anti-strand and thereafter gives a spurious positive hybridisation. One obvious way round this is to heat the transcript before thiol agarose chromatography. The hybrid strands separate and endogenous RNA is no longer copurified with the transcript. When this is done, however, the transcript no longer hybridises to globin cDNA.

R. S. Gilmour is at the Beatson Institute for Cancer Research, Glasgow.

An identical conclusion was reached by Giesecke *et al.* (*Nucleic Acids Res.* **4**, 3943; 1977) in their bid to detect the *in vitro* synthesis of ovalbumin in RNA sequences from chick oviduct chromatin with *E. coli* polymerase.

These reports are somewhat alarming since they would imply that no DNA-dependent gene-specific transcription can be detected in chromatin in which these genes are known to be active *in vivo*. How would this conclusion affect the interpretation of the vast bulk of chromatin transcription data accumulated over the past decade or so? Several comments spring to mind.

Before cDNA was available, chromatin transcripts were analysed qualitatively by hybridising purified *in vitro* labelled transcripts to denatured total DNA bound to nitrocellulose filters. The amount of label converted into RNase-resistant hybrid gave an estimate of sequence homology. In this analysis, transcription of endogenous RNA would give rise to a labelled copy which would hybridise to DNA in the same way as if correct DNA transcription had taken place except that the strand sense is reversed.

Gene-specific cDNAs have been made from ovalbumin, histone and a variety of globin messenger RNAs and used as hybridisation probes for chromatin transcripts. As already pointed out the data obtained are only valid where it can be shown that endogenous RNA sequences are not interfering with the analysis. Where this is so and it has not been considered necessary to resort to mercurated nucleotides it is difficult to see how gene-specific transcripts can arise other than by direct transcription of the DNA itself. However, a number of workers have indeed used the mercury technique, suggesting that endogenous RNA is a problem with chromatin in general. In this case the criticism of Zasloff and Felsenfeld is a valid one and unless steps are taken to avoid cross-contamination of transcripts with endogenous RNA the data cannot be sidered conclusive.

Attempts have been made to assess the fidelity of transcription from chromatin with respect to DNA strand selection by bacterial and isolated animal polymerases. In many cases where symmetrical transcription is seen this has been interpreted in terms of loss of enzyme specificity in *in vitro* conditions. However, endogenous RNA transcription rather than non-selective DNA strand copying might equally well account for the findings.

It should be mentioned that the strongest evidence for RNA copying presented by Zasloff and Felsenfeld and Giesecke *et al.* comes from experiments where purified mRNA is added to

The blind fishes of Persia

It was exciting to read the note by G. Thinès in *News and Views* (**271**, 305; 1978) which affirmed his 'great interest' in the discovery of two cavernicolous forms in the same well-like outlet. However, it is possible that a misunderstanding has occurred which needs to be corrected. The fish were indeed both found in the same well-like outlet; but this resurgence, which did resemble a well, was an entirely natural event. As much of the note's argument concerned the co-existence of cave forms in biotopes other than those of caves it is important to clarify the actual situation.

The two fish species were *Iranocypris typhlops* (Cyprinidae), first described by Bruun and Kaiser in *Dan. scient. Invest. Iran* **4**, 1-8 (1943, published 1950), and *Noemacheilus smithi* (Cobitidae), first described by P. H. Greenwood in *J. Zool.* (**180**, 129; 1976). The Danish paper, which also gives a photograph of the discovered location of *I. typhlops*, mentions that 'the water comes from the subterranean source in the background' of the picture. I discovered *N. smithi* by going to this precise spot and observing the blind loach in the same pool as the previously discovered blind carp. In his paper Greenwood confirms the Danish description and stresses the naturalness of this resurgence: 'There, exactly as described by Bruun & Kaiser, [Smith] found a small group of fishes swimming in the well-like outlet of a subterranean water-body. Since the habitat is fully exposed to light and in no way resembles a cave, it seems reasonable to suppose that the typically cavernicolous fishes living there are accidental strays from a true cave environment within the mountains.'

The case of *I. typhlops* coexisting with *N. smithi* is not similar to that of *Milyeringa veritas* and *Anommatophasma candidum*, or the other examples quoted by Thinès. Both *N. smithi* and *I. typhlops* have so far been found in only a single locality and that locality is neither a well nor an artificial outlet. It cannot be argued that their case is 'a typical instance of an already well-known

phenomenon, whose meaning for bio-speleological research is clear.'

What is still completely unclear is the nature of the true habitat of the blind fishes of Persia, so far discovered only in a single resurgence near Tang-e-Haft in the Zagros mountains. An attempt was made in 1977 by two caving experts equipped with breathing apparatus to gain access to the cave system. Greenwood and others considered that the 'well-like outlet' could not possibly be the sole habitat of the two Persian fishes. During the snow-melt period of spring this outlet always overflows to form a small stream, according to local villagers, but in May or June the overflow ceases. For the rest of each year the well of water has a surface area approximately 5 m by 3 m and this gradually decreases as the season progresses.

The two divers attempted their exploration in April when the outlet was no longer overflowing, it being an exceptionally dry year, and they descended to a depth of about 20 m. Right from the surface the resurgence narrowed until it became impossible for the men to progress further. Their opinion was that 'a major dry system did not necessarily exist within the mountain' and that 'a vast volume of water could be contained in a massive underground maze of flooded rifts' (personal communication). They thought it unlikely that anyone would find a way in to the real habitat of the Persian cave fishes as the nearby mountains 'were composed of limestone with very thin beddings, varying from 15 to 60 cms, which were almost vertical. Not only was the rock very friable, making major cave systems improbable, but any caves which did exist were likely to be high narrow rifts.' It would seem that, for the time being, the blind cave fishes of Persia are quite safe within their cave, save for the few of their number who stray inadvertently into a resurgence where they are (very occasionally) caught by passing naturalists.

transcription systems. However, it is probable that endogenous RNA does not exist in this free form and may be tightly bound within the chromatin structure. While it is not known whether this RNA can be copied by RNA polymerase, any cytoplasmic mRNA contaminating the chromatin might well produce an artefact. The levels of cytoplasmic globin and oval-

bumin mRNAs in these systems are extremely high and therefore it is still not clear whether the observations are due to an intrinsic feature of the chromatin structure or inadvertent cytoplasmic contamination. Whatever the answer, the impact of these findings should encourage workers in this field to examine their own particular systems with ruthless scrutiny. □

I SHOULD like to comment on the article 'Advances in Chinese Restaurant Research' (*News and Views* 267, 756; 1977). Unfortunately your anonymous correspondent seems unaware of the background to a field which may have some superficially amusing characteristics but, in fact concerns some potentially serious issues.

The topic of the Chinese Restaurant Syndrome is hardly 'gripping' the Boston Medical Research Community. In fact, although it mildly interests most people, it 'grips' only those who get fairly severe symptoms. In trying to point out that the name of this Syndrome was unfortunate (since glutamate is used in other types of restaurants), I gave as examples, Japanese, Italian and French; I did not feel that I had to enumerate the names of all types of cuisine available in the Boston area. 'All-American' establishments are by no means 'blameless'; if by All-American food one means steaks, for instance, it has been found in some establishments that an 8 oz steak is not unlikely to be 'doctored' with 0.9 g of monosodium glutamate. As for the listing of what the correspondent found to be a disagreeably large number of symptoms, I will quote, by comparison, a recent description of yet another ill-defined, but quite real human malady: Symptoms of 'Classic migraine . . . in addition to the head pain . . . may also include photophobia, nausea, vomiting, constipation or diarrhea, weight gain and fluid retention followed by diuresis, scotomas or visual field defects, paresthesias or defects in motility, vertigo, and elevation of blood pressure.' (from Dalessio *Dietary Migraine*, *Am. Family Phys.* 6 No. 6, 60; 1972).

A large literature exists on the effects of glutamate in both animals and humans. An interest in the adverse effects, to (presumably) glutamate, both in animals and in some humans, has existed for a number of years. It is fairly well established that parenteral

Chinese Restaurant Syndrome

administration of glutamate causes vomiting in humans. Various studies, primarily since 1968, have indicated that the so-called Chinese Restaurant Syndrome is probably caused by the raised levels of free glutamate that are frequently added to such foods. This general problem is of both theoretical and practical interest. Many people (including many physicians) are unaware of so-called Chinese Restaurant Syndrome; people with fairly severe reactions to what is presumably monosodium glutamate, have been unnecessarily caused extended periods of anxiety (thinking that they had some neurological problem) because of this lack of general knowledge. A number of young children have been subjected to extensive neurological testing and have apparently been misdiagnosed and incorrectly treated because of a lack of awareness of 'glutamate overload' intolerance. (Reif-Lehrer & M. G. Stemmermann *New Engl. J. Med.* 293, 1204; 1975; Reif-Lehrer, *Pediatrics* 58, 771; 1976.) There is also an increasing literature on glutamic acid as a neuro-excitatory substance and this amino acid is currently being examined as a putative neurotransmitter in certain cells. Numerous investigators have reported that young rodents treated with glutamate are subject to both retinal and hypothalamic damage. Similar results have been obtained in the hypothalamus of monkeys, but are more controversial.

Animals which have been examined do respond to glutamate overloading with convulsions. A variety of other responses in animals have also been reported, and either glutamate or aspartate are routinely used to eliminate the B wave of the electroretinogram of isolated retinas, again indicating damage to the cells of the inner retina. Several studies in humans, as well as animals,

have shown that ingestion of raised levels of free glutamate does indeed lead to abnormally high blood levels of this amino acid.

In the course of some studies concerned with glutamate metabolism in the retina, I became interested in the more general topic of glutamate metabolism in humans and in particular in a question which had apparently remained unanswered in the literature: namely, how many people experience the strange phenomenon called Chinese Restaurant Syndrome, and what may be different about the metabolism of these sensitive individuals. The fact that this issue is of importance to others may be attested to by public hearings (July 25-26) before the FASEB Select Committee on GRAS Substances on Glutamates, which were held in Washington. A final report of this Committee should be ready early in 1978. The opinion expressed in the tentative FASEB report and confirmed at the Washington hearings was, that the issues concerning glutamate consumption are of importance and need further exploration. Such further exploration will of course, require time, money, appropriate expertise, and an interest on the part of the scientific community to explore the question without preconceived bias.

LIANE REIF-LEHRER

Eye Research Institute of Retina
Foundation*

Our correspondent replies: I am very sorry that Dr Reif-Lehrer mistook my light-hearted comments for an attack on research into the harmful effects of glutamate. What I did intend to question was the usefulness of accumulating a vast body of anecdotal reports, when they are not accompanied by parallel tests for the substance in question. This kind of approach makes it all too easy for the food industry to cry 'not proven'.

A hundred years ago

FROM the last report of Dr. Dohrn, the director, we notice that the zoological station at Naples has developed a most remarkable degree of activity, and is becoming a valuable centre of biological research. By the generosity of the Prussian Government it has been provided with a small steamer, and the uninterrupted expeditions in this vessel have secured to the laboratories an enormous and most varied stock of material for research. Dr. Dohrn has

carefully organised a plan for the systematic examination of the entire fauna of this part of the sea, to be accompanied by exhaustive description. The literary portion of the work will consist of elaborate monographs on all the families and species represented in the Gulf of Naples. They will not be prepared by the members of the station only, but it is hoped to procure the assistance of all familiar with this special department, and the contributions can be in English, French, German, or Italian. Two monographs on the Elenophorae and Balanoglossi will appear during the present year, and arrangements have been made for the speedy preparation of eleven others.

THE Radicals in the French Chamber cannot be accused of opposition to the claims of science. We notice that in a

late session a member of the extreme left proposed an amendment to the budget of instruction, which provided for the appropriation of 30,000 francs for an expedition to California to observe the next transit of Mercury, 40,000 for the continuation of the explorations in Northern Africa, where it has been proposed to admit water from the Mediterranean, and 100,000 to enable the Abbé Debès to make a journey across Africa from Zanzibar to the Congo. As the appropriation was granted, we may hope soon to see the latter portion of it cause the appearance of a new rival of Stanley, for the Abbé has had, like Livingstone, invaluable experiences as a missionary, which will enable him to enter upon the undertaking with great promises of success.

review article

Repair deficient human disorders and cancer

R. B. Setlow*

The analysis of the repair of damage to DNA in mammalian cells leads not only to a knowledge of which environmental agents are deleterious to living creatures, but also to an understanding of which reaction products in DNA are potentially carcinogenic and which tissues are the more sensitive.

In a number of recessively inherited human disorders, the affected individuals are cancer prone¹. The prevalence of cancer among such individuals ranges from significantly higher to orders of magnitude higher than in the general population²⁻⁴. Three of these disorders—xeroderma pigmentosum (XP), ataxia telangiectasia (AT) and Fanconi's anaemia (FA)—are associated with defects in the ability of cells to repair certain kinds of physical or chemical damage to their DNA. The existence of such disorders is direct evidence that damage to DNA can be carcinogenic, and is the best available evidence for a causal association between mutagenic and carcinogenic agents—an association used extensively as an environmental detection screen for carcinogens⁵. The support for the causal connection is further strengthened by the observation that mutations occur in XP cells at lower doses of carcinogens than those affecting normal cells⁶.

The clinical symptoms of the disorders are completely different, as are the known defects in repair. XP is characterised by the extreme sensitivity of skin to sunlight^{3,4,7}; AT by progressive cerebellar ataxia and dilated blood vessels in the eye, as well as immune deficiencies⁸; and FA by haematological abnormalities that ultimately lead to death as a result of haemorrhage or haematological failure¹. FA may also include various skeletal deformities. The diseases are rare, approximately one in several hundred thousand births, but heterozygotes are estimated to be one in several hundred⁹. However, heterozygotes do not show indications of the disorders and are not cancer prone, except in FA for which there is evidence of a higher risk of leukaemia. It has been estimated that 5% of all individuals dying of acute leukaemia are FA heterozygotes⁹. Thus, although the diseases are not general public health problems, analysis of the molecular defects in them should elucidate the molecular nature of the changes responsible for killing, mutagenesis and carcinogenesis, and give estimates of the probability that such changes result in biological effects. Since human risks can only be assessed from data on molecules and animals extrapolated to humans, usually by means of scanty epidemiological data, it is important that we have an understanding of the molecular mechanisms involved so as to provide a theoretical base for the extrapolations. Such a long-range, seductive goal has led to a wide range of investigations on the association of repair defects with other human conditions, including ageing and high blood pressure.

Almost all our notions about the molecular nature of repair come from studies on bacterial systems because of the large number of genetically well defined repair-deficient mutants and the relative ease in analysing photochemical and molecular changes in them^{9,10}. The genetic analysis of repair in mammalian systems is based on the naturally occurring human

inherited diseases. The concepts are simple but the problems are complex because physical or chemical agents make more than one change in DNA and there is no reason to assume that the changes have large biological consequences in normal cells. If a particular product is repaired well in normal cells and not in sensitive ones, it may be that the product is bad for the latter but innocuous for the former. Moreover, if a product is not repaired in both normal and sensitive cells, one cannot assume without other information that it has any biological effect. For ultraviolet radiation there are experimental tricks that permit one to show that pyrimidine dimers alter the biological function of DNA and affect both sensitive and resistant cells, even though the latter are highly proficient in excising dimers. The trick is to use the fact that photoreactivating (PR) enzymes in the presence of light are able to break pyrimidine dimers into monomers without affecting any other known photoproduct⁹. Hence, if ultraviolet (UV) affects some biological function and the effect of ultraviolet is ameliorated by subsequent exposure to PR light, one can assume that the initial biological effect arose from dimers in DNA. Such a conclusion does not indicate the molecular mechanisms by which dimers produce their effects. They could be the induction of viruses, changes in transcription or inhibition of repair of other products. The identification of dimers as inactivating transforming DNA, killing and causing mutations in bacteria, transforming fish cells, and inhibiting DNA synthesis in human cells means that ultraviolet is the best understood model for environmental carcinogenesis^{9,11,12}.

Excision defective XP cells seem to be analogues of the *uvrAB* mutants of *E. coli*. However, details of excision in *E. coli* are not well known because even though the *uvrAB* endonuclease makes single-strand nicks in UV-irradiated DNA, one can easily calculate from published data¹³ that the number of nicks are many-fold fewer than the numbers of dimers. Hence, the action of the endonuclease *in vitro* seems to be on minor photoproducts in DNA. Similar conclusions are reached about most of the UV endonucleases that have been isolated from prokaryotic or eukaryotic systems. Exceptions are those isolated from *M. luteus* and from T4 phage infected *E. coli*^{9,10}. It is no wonder that the details of repair of UV damage in human cells, where in XP there are at least five complementation groups⁷, are not known.

Types of repair

The existence of cell strains sensitive to certain environmental agents does not imply that the sensitivity arises from a defect in repair unless one can show that the initial deleterious products occur in similar numbers in both sensitive and resistant cells. But this demonstration requires a knowledge—usually incomplete—of what the products are. Hence, the best way to assess the role of repair is to measure host cell reactivation—

*Biology Department, Brookhaven National Laboratory, Upton, New York 11973.

the ability of cells to affect the survival of viruses treated with chemical or physical agents outside the cell. Low survival is interpreted as a defect in repair. The technique is applicable to unknown types of damage and to unknown types of repair system.

The direct measurement of excision repair requires determination of loss from DNA of products that have biological consequences. It is this latter aspect of the problem that has led to the emphasis on pyrimidine dimers in DNA^{9,14}. In subsequent experiments one can use indirect measures of repair such as unscheduled DNA synthesis, repair replication or the photolysis of incorporated BUdR^{9,14}. These techniques can be used as measures of DNA repair even though they do not identify uniquely what change is repaired or the changes that are biologically important. However, defective repair may not be readily apparent because a product of little biological consequence may well be repaired whereas a minor product with important biological consequences is not well repaired. This seems to be the case for alkylation damage to DNA. Both normal and XP cells are able to remove readily *N*⁷-alkylGua, but only normal cells can do it for the minor product *O*⁶-alkylGua¹⁵. Nevertheless, the various measures of excision repair usually give similar results. In cells with a low level of excision repair for dimers, repair replication is not necessarily an adequate measure of dimer excision because, presumably, repair replication also detects repair of minor photoproducts.

At a mean lethal ultraviolet dose to excision-defective cells there are many dimers per cell⁹. Hence, cells have evolved effective ways of bypassing alterations to their DNA. In both bacterial and mammalian systems the DNA made on a damaged template is often smaller than that made on undamaged ones¹⁶. The small DNA is subsequently chased into pieces the size of the parent, and the process of chasing the small DNA into large is called post-replication repair. In a number of instances the size of the small DNA is compatible with the idea that pyrimidine dimers act as blocks to synthesis, and this notion is reinforced by the observation that PR treatment before the pulse label results in much larger DNA in bacterial, marsupial, and chicken cells¹⁶; in all of which PR illumination breaks dimers into monomers. In bacteria the new DNA acts as if it contains gaps and the gaps are filled in by exchanges between parental and daughter DNA. Post-replication repair is defective in *rec*⁻ and *lex*⁻ mutants of *E. coli* and in such cells susceptibility to mutation by UV radiation is also greatly reduced¹⁷. These and other arguments have led to the notion that at least a part of post-replication repair in *E. coli* is inducible by small doses and such doses induce a new protein, the so-called protein X¹⁷. The appearance of this new protein is associated with the fixation of mutations.

It is reasonable to carry over these ideas to mammalian cells but the molecular mechanism involved in post-replication repair in mammals is in dispute. In some experiments the newly synthesised DNA acts as if it contains gaps that are filled in during post-replication repair and the gaps were estimated to be about 1,000 nucleotides long¹⁶, although more recent estimates put the number closer to 200 (R. B. S. and E. Grist, unpublished). There seem to be comparatively few exchanges¹⁸ and the evidence for the existence of gaps in the newly replicated DNA comes only from experiments on the photolysis of DNA repaired in the presence of BUdR. Synthesis may take place by a replicative bypass mechanism^{19,20} without production of gaps and there is evidence that the gaps, if any, are not opposite the dimers in the parental DNA^{21,22}. Perhaps both modes of synthesis take place. Post-replication repair is defective in XP variants but it can be speeded up by pretreatment of cells with small doses of ultraviolet or *N*-acetoxy-AAF^{24,25}. The role, if any, of this enhanced repair is not clear. It takes place not only after split doses but also with single doses (R. B. S. and E. Grist, unpublished). The role of post-replication repair in mutagenesis can be identified in bacteria because it is possible to remove the lesions at known times by PR treatment¹⁷. Such a technique has not been developed for mammalian cells. It

is an intriguing observation that protease inhibitors that block the induced repair functions in *E. coli* also acts as inhibitors of tumour promotion²⁶.

Defective excision or post-replication repair does not seem to be involved in the formation of spontaneous sister chromatid exchanges since various XP cell lines show no significant differences from normal cells²⁷. However, treated, excision defective XP cells always show more sister chromatid exchanges independent of the repair capability of the cells for the major product of the chemical agent²⁷. Hence, the main chemical damage detected as affecting DNA is not necessarily that responsible for chromosomal effects, although for ultraviolet the PR of chromosome aberrations in marsupial cells indicates that pyrimidine dimers are important²⁸. In any event increases in chromosome aberrations are correlated with decreases in excision repair, although sister chromatid exchanges are not²⁹.

Xeroderma pigmentosum

Xeroderma pigmentosum is the most widely studied repair-deficient human disease⁷. Affected individuals develop light-induced skin cancer with a prevalence among whites at age 20, of approximately 100%—a value at least 10³-fold greater than for the general population³⁰. All XP cells are defective in at least one mode of repair of ultraviolet damage to DNA. Most XP individuals have a defect in the excision repair pathway for ultraviolet damage. The defect is not complete, but may be over 90% in some individuals and only 50% in others⁷. Although few quantitative comparisons of repair kinetics have been made by one laboratory using several methods, it is comforting that similar estimates of the extent of excision defects are found by a number of different techniques, such as cell survival and mutation after irradiation⁶, ability to reactivate ultraviolet inactivated viruses³¹, the loss of dimers from DNA¹⁴, loss of ultraviolet endonuclease sensitive sites³², unscheduled DNA synthesis⁷, and repair replication¹⁴ either by direct observation or by the photolysis of incorporated BUdR. Among the excision-defective individuals there is a good correlation between the severity of the molecular defect and the severity of the disease³³, although the latter also must depend on the exposure to the deleterious wavelengths in sunlight. The fact that the mutation frequency per unit dose is higher in these XP cells, but that the frequency at a given survival is the same for normals is a biological indication that excision repair is error-free⁶. Biochemical and biophysical data indicate also that excision repair makes no large errors³⁴.

The defect in excision seems to be associated with a malfunction of the incision step during incubation after UV irradiation of XP cells, since only small numbers of single strand breaks are observed compared with the numbers of dimers in DNA^{14,35}. Moreover, when T4 endonuclease is introduced into irradiated XP cells, unscheduled DNA synthesis approaching normal levels is observed and the introduced enzyme increases cell survival³⁶. Excision defective cells fall into five complementation groups⁷. Hybrids of any two are close to normal in unscheduled synthesis, repair replication and loss of sites sensitive to ultraviolet endonuclease, as well as by the ability of such heterokaryons to reactivate ultraviolet irradiated viruses. One might think that active endonuclease is formed in the heterokaryons from diffusible parts of inactive multimeric enzymes. However, sonicates of XP cells are able to excise dimers from exogenous DNA but are not able to excise dimers from their own chromatin, whereas normal cells are³⁷. Thus, the nature of the molecular defect in XP cells is not known.

A sixth group of xeroderma pigmentosum individuals is proficient in excision repair. The existence of these individuals was an important exception to the association between the severity of repair defect and the severity of the disorder. However, cells of this group are now known to be defective in post-replication repair²³, are more sensitive to ultraviolet radiation⁶, and are not fully proficient in host cell reactivation³⁸. More-

over, not only the mutation frequency at a given dose, but the mutation frequency at a given survival is higher than that of normal cells, implying that some steps in repair of XP variant cells are more error-prone than in normal or in conventional XP cells³⁹.

The experiments summarised above use acute exposures of cells to 254 nm radiation at doses of 1–20 J m⁻². People receive much smaller equivalent doses per exposure. One minute exposure to the noon sun in Texas in September would be equivalent to approximately 0.1 J m⁻² of 254 nm⁴⁰ and the amount transmitted through the upper inert layer of skin would be closer to 0.01 J m⁻². Hence, the actual carcinogenic environment is a far cry from the experiments done in the laboratory. Moreover people are exposed to strong visible light at the same time that they are exposed to ultraviolet. Human cells have PR enzyme activity and XP cells in culture have less activity than do normals⁴¹. Although the enzymatic activity of cells in culture depends upon the culture medium⁴², it is reasonable to suppose that the enzyme would act *in vivo* and that the number of dimers in cells would be determined by the relative levels of ultraviolet and visible radiation and the PR and excision enzymes. It is intriguing that in all the XP cell lines investigated the sum of the three repair activities: excision, post-replication, and PR is about one half of normal⁴³.

The fact that all XP cell lines are defective in one or more repair pathway for UV damage makes it attractive to speculate²⁴ that UV-induced skin carcinogenesis in normal human-beings has a low probability because most of the lesions are removed and DNA synthesis beyond any that remain is relatively error free. In excision defective XP cells many dimers remain and replication beyond them, although relatively error free, makes an appreciable number of mistakes and hence gives a high possibility for neoplastic transformation. In the XP variants there are a few more dimers than in normals because of a defect in PR, but replication beyond dimers is error prone and, as in the case of conventional XPs, an appreciable number of mistakes is made. Similar speculations have been made for chemical damage⁴³.

From ultraviolet to chemicals

Bacteria that are defective in repairing ultraviolet damage are also defective in repairing a number of other damages to DNA, for example, nitrogen mustard, 4-NQO, and the effects of black-light plus psoralen^{9,44}. Hence it is not surprising that the same is true for XP cells, and the repair of damaged DNA is more general than just the special case of repair of pyrimidine dimers. There are several damaging agents that are repaired effectively in XP cells⁴⁵⁻⁴⁸. Such damage results from ionising radiation, the photolysis of BUdR and the action of simple alkylating agents. Repair in these cases involves both the repair of single strand breaks and probably excision repair mediated by *N*-glycosidases¹⁰ or by spontaneous base removal followed by the action of an apurinic endonuclease¹⁰. However, apurinic endonuclease isolated from XP cells shows changes when compared with the normal enzyme⁴⁹. The classification of chemical agents as making repairable or irreparable damage in XP cells is useful but not unique because a number of different products may be formed from a single agent. For example, alkylation of DNA affects many groups. The *N*⁷-alkylGua is removed efficiently in XP cells but the *O*⁶-alkylGua is not⁴⁵. Table 1 lists agents and products in terms of their repair by XP, AT, and FA cells. In the small number of cases that have been investigated carefully the sizes of the patches for agents repaired effectively by normal cells, but not by XP cells have been measured. The patches are large (30–100 nucleotides) and they are an order of magnitude larger than the number of bases inserted during repair of single strand breaks⁴⁶⁻⁴⁸.

The simplicity of the above picture is deceptive. One might suppose that the compounds mimicking ultraviolet would be acted upon by common repair pathways since the rate-limiting step in their repair is considered to be the initial endonucleolysis

(see above). However, acetylaminofluorene (AAF) and ultraviolet-induced damage do not compete for this putative common step. AAF treatment of normal human cells does not inhibit dimer excision at ultraviolet doses that saturate the excision pathway⁶⁹. Thus, our molecular picture of excision is far from complete. Nevertheless, agents that mimic the ultraviolet effect of excision also mimic its effects on cell survival and mutagenesis^{6,7} and in post replication repair. Moreover, in XP variants post-replication repair after ultraviolet or AAF is enhanced by treatment of the cells several hours earlier with small doses of either ultraviolet or AAF^{24,25}.

Repair in transformed or differentiated cells

As a general rule proficiency in repair of physical or chemical damage to DNA is independent of the cell type or tissue of origin. For example, transformation of cells by SV40 virus does not affect the ability or inability to repair ultraviolet damage⁷ and all tissues tested from XP individuals^{3,70}, including melanoma cells, are as defective in repair as are fibroblasts or lymphocytes. Moreover, tissues from non-XP individuals repair ultraviolet damage whether the tissues represent material from spontaneous tumours or normal tissue⁷⁰. Nevertheless, repair does not seem to be uniformly distributed over the chromosomes or throughout chromatin^{71,72}.

There are important exceptions to the above generalisation: (1) lymphocytes stimulated by concanavalin A are 10-fold more proficient in unscheduled DNA synthesis after AAF treatment than are unstimulated lymphocytes⁷³. It was concluded that the rate of excision is a function of the capacity for DNA synthesis and that unstimulated lymphocytes cannot readily be used to distinguish repair arising from agents that give rise to long patch repair from those that give rise to short patch repair. (2) Some melanoma cells are very resistant in culture and resistance is not associated with a lower yield of ultraviolet induced dimers nor with an increase in the rates of excision or post-replication repair⁷⁴. (3) Mouse fibroblasts are defective in excision repair of ultraviolet damage^{48,75} and so are epithelial cells in mouse skin⁷⁶. (The interpretation in an earlier report⁷⁷ of excision of mouse skin is confounded by the high surface, but low average, dose of 254 nm.) However, early passage cells from 13–15-d-old mouse embryos excise dimers from DNA into the acid soluble fraction of the nucleus⁷⁸. Cells from passages greater than 7 cannot do this nor can early passage cells from 17–19-d-old embryos. The latter are like cells from adult animals or most rodent cells in culture in that they do little excision repair of pyrimidine dimers. Similarly, after UV irradiation myocardial cells from newborn rats show extensive unscheduled DNA synthesis compared with cells from 3–12-month-old animals⁷⁹. These findings raise the possibility that the mutations leading to the XP phenotype are not in structural genes for proteins involved in excision repair, but are alterations in control elements that result in shutting off portions of repair pathways.

Ataxia telangiectasia

The association between exposure to sunlight and high prevalence of skin cancer in XP made it relatively easy to relate the disease to defects in repair of ultraviolet damage, especially since there were good hints from prokaryotes that pyrimidine dimers were typical lesions to be investigated. AT is more difficult to understand at the molecular level because cancer in this disease has not been associated with a particular environmental agent. The realisation that AT individuals are sensitive to X rays (see ref. 60), and that their levels of spontaneous and radiation induced chromosome aberrations are increased⁸⁰ led to the demonstration that fibroblasts from affected individuals are 3–4-fold more sensitive to X rays than normal cells⁶⁰. AT cells are proficient in the repair of ultraviolet^{83,84} and AAF damage⁸⁵. The main biological effects of X rays are thought to be base damage—perhaps double-strand breaks⁹.

All the AT cell lines investigated are proficient in the repair of single- and double-strand breaks^{60,61}. However, 6 out of 12 lines are defective in repair replication following anoxic irradiation⁶². (Anoxic radiation enhances the proportion of base damage to single-strand breaks.) Four of the cell lines showed normal repair replication. Hence, AT is genetically heterogeneous as is XP. Among three of the repair defective cell lines, fusion studies showed that there were two complementation groups⁶².

Table 1 Damaging agents or products for which cells are repair proficient or deficient

Xeroderma pigmentosum	
Proficient	Deficient
	Ultraviolet
	—dimers
	—protein DNA links ⁶⁰
	—strand breaks ⁶¹
Ionising radiation	Ionising radiation—anoxic

MNNG	Psoralen + light
4—NQO	HN ₂
MMS	DNA crosslinks
	γ-rays ⁶⁷
Ultraviolet	Ultraviolet (high dose) ⁶⁸

Cells are categorised on the basis of survival, host cell reactivation, or by chromosomal, biochemical or biophysical measures of repair. (A listing in both categories means that there are several products of an agent or that all cell lines are not the same. In addition to specific references consult the text and refs 7, 14, 45–48.)

A protein extract from *M. luteus* makes single-strand breaks in DNA X ray-irradiated *in vivo* or *in vitro*. The extract can be used to determine whether such nuclease sensitive sites are removed from DNA during incubation following irradiation. Two cell lines defective in repair replication were assessed by this technique and were found to remove endonuclease sensitive sites at a much slower rate than normal cells⁶². The nature of the alteration that is not excised is unknown. It could be thymidine damage of the hydroxy hydroperoxide type even though such damage is removed readily from exogenous DNA by cell sonicates of repair defective cells⁶⁰ because, as in the case of pyrimidine dimers and XP sonicates³⁷, such sonicates might not mimic conditions *in vivo*.

The repair defects in AT are not confined to X rays but include chemical damages as well (see Table 1). Hence, there is a strong possibility of identifying the molecular nature of some

of the damages repaired poorly in AT and perhaps estimating whether there are particular environmental hazards associated with the initiation of cancer in this disease.

Fanconi's anaemia

A genetic analysis indicates that the defect is heterogeneous⁸¹. Cells from affected individuals show more spontaneous chromosome aberrations than do normal ones⁵⁹, and treatment of cells with DNA cross-linking agents such as nitrogen mustard, mitomycin C, or psoralen plus black light gives rise to 30-fold more chromosomal aberrations than observed in treated normal cells⁶⁶. Monofunctional agents do not give rise to such a big difference although the number resulting from UV irradiation is approximately fivefold more than in normal cells⁶⁶. These data are interpreted as indicating that FA cells have a defect in the repair of cross links⁶⁸. On the other hand treatment with mitomycin C results in a decrease in the numbers of sister chromatid exchanges⁸².

FA cells are appreciably more sensitive to killing by mitomycin C than are HeLa or XP cells and their DNA, analysed on alkaline gradients immediately after treatment, sediments more rapidly than DNA from untreated cells⁶⁸. At 4 h after treatment more of the DNA is larger than immediately after treatment. These data indicate that cross linking reactions take place after treatment. In normal or XP cells treated with mitomycin C a decrease in molecular weight is observed immediately after treatment, and in several hours the size of the DNA from treated cells returns to normal. The pattern of changes is as if an endonuclease breaks the affected DNA and repair is completed by excision, polymerisation and ligation. The repair of mitomycin C damage seems to be by pathways different from that of ultraviolet damage since cells that repair such damage show few strand breaks during repair^{14,35}.

FA cells may also be slightly defective in the repair of γ-ray and ultraviolet damage. γ-irradiated adenovirus does not grow as well on FA cells and, at high doses, ultraviolet irradiated virus does not grow as well as on normals⁶⁷. At high doses, but not low, the excision repair of γ-ray products or of pyrimidine dimers seems defective⁶⁸. However, as for all cells investigated to date, the repair of single strand breaks is not deficient, but in cell homogenates, the ability to remove high doses of t⁺ from exogenous DNA is defective in two of four cell lines investigated⁸³.

Bloom's syndrome

A repair deficiency is inferred from the finding of large numbers of spontaneous chromosomal aberrations and well over a 10-fold increase in sister chromatid exchanges in untreated lymphocytes^{1,59,84}. Lymphocytes from some individuals have a bimodal distribution of the sister chromatid exchanges⁸⁴. This finding suggests that the syndrome results from changes at a regulatory rather than a structural locus. The dimorphism is not observed in fibroblast or bone marrow cells. The chromosomes are more sensitive to radiation⁵⁹ and the cells are slightly more sensitive to ultraviolet⁸⁵. The rate of fork motion during DNA replication is slower than normal in Bloom's syndrome⁸⁶ and might account for the observation that the sedimentation of pulse labelled DNA after UV irradiation is somewhat slower than in normal cells⁸⁵.

Other human diseases and conditions

The successes in correlating some diseases causing cancer proneness with defects in DNA repair have led to searches for other repair deficient diseases. Light sensitive diseases other than XP have not been found to be defective in excision of ultraviolet damage⁸⁷. However, individuals with actinic keratoses—a potential precarcinogenic condition—have slightly decreased levels of unscheduled synthesis⁸⁸, and high blood

pressure has been associated with a decrease in repair and an increase in chromosomal aberrations in lymphocytes treated with AAF⁸⁹. The cells of Cockayne's syndrome are reported to be ultraviolet sensitive, but the molecular defect is not known⁹⁰.

The screening of cells for X ray-sensitivity has indicated that cells of D-type retinoblastoma individuals are more X ray-sensitive than normals or those of familial retinoblastoma⁹¹. On the other hand fibroblasts from four individuals with abnormal responses to X rays have normal survival curves and normal repair of single strand breaks⁹².

Two general types of experiment have been done in attempts to correlate ageing with changes in DNA repair. In the first the repair capabilities of young and old cells in culture were compared and in the second cells with syndromes of premature ageing were investigated. Both gave somewhat equivocal results. Cells from some progeroid individuals were reported to be defective in the repair of single-strand breaks arising from ionising radiation⁹³, but other investigators have not been able to obtain these results^{94,95}, and chromosome breakage is not abnormally sensitive in these cells⁹⁶. However, measurements of the ability of γ -ray irradiated adenovirus to grow on progeroid cells indicates that they do have some deficiency⁹⁷.

Late passage cultures may or may not show reduced capacities to repair damages of various types⁹⁸⁻¹⁰⁰ but the reduction, at least for ultraviolet damage, is not uniformly distributed among cells¹⁰⁰. Cells that do not go through the cell cycle do not do appreciable unscheduled synthesis, but late passage cells that do cycle do repair. Hence, there is no evidence that a defect in repair leads to senescence. It might be a consequence of it. I interpret the intriguing correlation between DNA repair in ultraviolet irradiated cells in culture and the life span of the donor animal⁷⁵ not as indicating a casual relation between life span and repair, but a consequence of the turning off of parts of the repair system at early ages in the development of some animals.

Conclusion

Cells from most individuals are proficient in the repair of DNA damage. Retrospective studies have shown that individuals defective in repair are cancer prone and our knowledge of the molecular nature of the defects leads to the strong prediction that unrepaired damage to DNA has a high carcinogenic potential. The complexity of carcinogenesis, on the other hand, also indicates that not all cancers arise from defects in repair. Nevertheless, even in normal individuals the rate of DNA repair compared with other cellular processes should be an important parameter in the initial steps in carcinogenesis. Hence, an understanding of the control and kinetics of repair processes is as important as a knowledge of the activation and inactivation pathways for chemical carcinogens in extrapolations of carcinogenic hazards to humans.

This research was carried out at Brookhaven National Laboratory under the auspices of the United States Department of Energy.

Measurement of magnetic fields in a tokamak using laser light scattering

M. J. Forrest, P. G. Carolan & N. J. Peacock

Culham Laboratory (Euratom/UKAEA Fusion Association), Abingdon, Oxon UK

Local magnetic fields in a tokamak plasma have been measured by laser light scattering from the free electrons. This technique exploits the sensitivity of the cyclotron modulation of the scattered light spectrum to the angle between the local magnetic field and the plane in which the scattered light is observed. Theoretical constraints for observation of the modulated light spectrum are satisfied in the experimental conditions. Sufficient accuracy is achieved to derive the detailed volume current distribution—an essential factor in the energy balance and in plasma stability. The method may be applied to the considerably larger fusion research facilities currently envisaged.

IN controlled fusion devices such as tokamaks with strong magnetic fields, the gross stability and equilibrium of the plasma are governed by the pitch angle of the force lines¹. The strong toroidal field, B_ϕ , combined with the relatively weak self field, B_θ , due to axially driven heating currents, as shown in Fig. 1a, can provide a stable configuration for the plasma. This paper reports on measurements of the distribution of field directions from which the poloidal field distribution, $B_\theta(r)$, can be calculated. The equilibrium and stability behaviour of the plasma can then be studied in terms of the stability factor¹ q ($q(r) = rB_\phi/RB_\theta$). Measurement of $B_\theta(r)$ allows the current density profile, $j(r)$, to be calculated from the B_θ field distribution which gives the local ohmic heating rate and effective charge, Z_{eff} .

Following the first successful measurements of the electron temperature distribution in tokamaks using laser beam scattering², we have tried to bring magnetic fields within the set of plasma parameters which can be measured by this technique, as it uniquely offers high spatial and temporal resolution without perturbing the plasma.

It has been shown theoretically^{3,4} that the magnetic field influences the scattered light spectrum only when the differential wave vector $\mathbf{k} = \mathbf{k}_s - \mathbf{k}_o$, Fig. 1b, is nearly perpendicular to the local magnetic field vector, \mathbf{B} . When this condition is satisfied the spectrum is frequency modulated with peaks separated by the electron cyclotron frequency, ω_{ce} . Here we exploit the sensitivity of the depth of modulation to the angle between \mathbf{k} and \mathbf{B} . Due to the way in which the ohmic currents $j(r)$ are distributed through the plasma, the magnetic fields and their pitch angle, ε illustrated in Fig. 1, vary with plasma radius. Numerically, $\varepsilon = \arcsin B_\theta/B_T$ where $\mathbf{B}_T = \mathbf{B}_\phi + \mathbf{B}_\theta$. In tokamaks, the toroidal field B_ϕ can be set with considerable accuracy ($\lesssim 1\%$) so that the pitch angle $\varepsilon(r)$ is the quantity of immediate interest.

Measurement of the radial variation in pitch angle in the present study is based on the detection of those particular scattering planes, that is, planes defined by the directions of

the incident and scattered light, which show frequency modulation of the spectrum.

Unfortunately, in low density, $n_e \approx 10^{19} \text{ m}^{-3}$, high temperature, $T_e \approx 1 \text{ keV}$, plasmas as in tokamaks, the scattered light flux in the individual harmonics is too weak to be recorded directly. We overcame this difficulty by using light collection optics and a Fabry-Perot dispersion system which 'multiplexes' the harmonic content to a detectable level. The Fabry-Perot allows the angular information in the dispersed spectrum to be related to the variation of field line pitch angle with radius of the plasma column.

Other experimental studies of the location of magnetic surfaces in tokamaks have been reported recently. Alladio and Martone⁵ have determined a local current density by measurements of the displaced Gaussian scattered spectrum. In high temperature tokamaks, such a measurement is difficult because of the low ratio of the drift to thermal speed for the electrons, typically $v_d/v_e \approx 0.03$. Non-scattering methods include second harmonic generation at the upper hybrid frequency in the ST tokamak⁶ and the location of q surfaces by collimated neutral deuterium beams traversing the ATC tokamak⁷. Another technique by McCormick *et al.*⁸ involves the detection of σ and π components of the Zeeman-broadened emission lines from a neutral lithium beam which is directed through the plasma.

Theoretical background

When the scale length, k^{-1} , of the scattering geometry, as defined by the laser wavelength and scattering angle, is much less than the plasma Debye length, λ_D , only uncorrelated motions of the scattering electrons are represented in the

Fig. 1a, The magnetic field configuration in a tokamak. b, Vector diagram for scattering in a magnetic field. Full lines show situation where there is no B_θ field—on the magnetic axis. Dotted lines indicate how the wave vector plane rotates as B_θ assumes finite values.

Fig. 2 Scattered spectrum for a magnetised plasma for \mathbf{k} almost perpendicular to \mathbf{B} .

Doppler broadened scattered spectrum. A single electron in the presence of a magnetic field will gyrate about a field line so that the velocity component in the \mathbf{k} direction will vary sinusoidally in time at the gyro frequency $\omega_{ce} = eB/m_e$. If the radius of gyration exceeds the scale length, the frequency modulated scattered spectrum will be a sequence of lines separated by the gyro frequency. The detailed spectrum of light scattered by an ensemble of electrons in a magnetised plasma has been calculated by Lehner and Pohl⁹:

$$S(k, \omega, \psi) = \frac{1}{\pi z^2 k v_e \sin \psi} \sum_{n=-\infty}^{+\infty} \exp(-n^2 z) \times \exp \left[- \left(\frac{\Delta \omega - n \omega_{ce}}{k v_e \sin \psi} \right)^2 \right]$$

where $z = k^2 r_L^2 \cos^2 \psi$ and ψ is the angular deviation from perpendicularity of the scattering vector \mathbf{k} to the field \mathbf{B} . It consists of a series of Gaussian peaks of width $2k v_e \sin \psi$, separated by the gyro frequency, Fig. 2. The peaks are bounded by a Gaussian of $2k v_e$ width, limiting their number to approximately $2k v_e / \omega_{ce}$ (or $2k r_L$, where r_L is the Larmor radius). Clearly, when $k \sin \psi v_e \simeq \omega_{ce}$ the modulation will disappear; this shows the critical dependence of the effect on the orthogonality angle ψ . A factor of 2 change in the ratio of these two quantities, that is, $k \sin \psi v_e / \omega_{ce}$, may cause the degree of modulation to change from about 90% to 15%. In the present experiment with a ruby laser the angle ψ has to be less than 0.5° for modulation to be observed. Other practical factors such as the finite acceptance cone of the scattered light and the variation in magnetic fields over the scattering volume will contribute to demodulation¹⁰.

Experimental background

Experimental evidence of modulated scattered light spectra from relatively dense ($n_e \simeq 10^{22} \text{ m}^{-3}$) plasma has been reported by Evans and Carolan¹¹, Kellerer¹², and Ludwig and Mahn¹³ who succeeded in resolving individual gyro peaks. However, in tokamak discharges with typical densities of $n_e = 10^{19} \text{ m}^{-3}$ there are too few scattered photons to allow for the detection of individual peaks.

Sheffield^{14,15} proposed an elegant solution to this problem by multiplexing the harmonic content of the scattered light spectrum, that is, effectively adding up all the peaks. Physically this entails setting the free spectral range, ω_{FSR} , of a Fabry-Perot interferometer equal to the gyro peak spacing, ω_{ce} . If smearing of the multiplexed harmonics is to be avoided this matching must be achieved with an accuracy better than the

reciprocal of the number of peaks that will be detected, that is, 0.6% in the present experiment.

Inherent in the proposal is the fact that the scattering directions containing modulated light can be identified as 'bright-up' spots in azimuth of the Fabry-Perot fringe, Fig. 4. The scattered spectrum exhibits modulation in only one plane, defined by the scattering geometry and field direction. The intersection of the plane and the Fabry-Perot ring pattern results in a partial fringe, which is measured as an azimuthal angle ' μ '. The Fabry-Perot has advantages such as high throughput and retention of the angular information through the disposition of the partial fringes.

The interpretation of the azimuthal fringe shift ' μ ' in terms of magnetic field directions is given in a generalised treatment by Carolan¹⁶ which holds for all scattering arrangements and plasma field configurations. An illustration of this, suitable for tokamak application, is shown in vector form in Fig. 3. When the scattered light is scanned along the laser beam, the wave vector plane containing the modulated spectrum, rotates about the laser beam direction due to the B_θ variation (see also Fig. 1b). Two examples are shown, with and without a B_θ field component; the cones represent collected scattered light directions. In the case where $B_\theta = 0$ the 'bright-up' of the fringes occur in the plane LOA; when B_θ is finite they appear in LOA'. For larger values of the scattering angle θ the plane of modulated light gives larger values of azimuthal angles μ_{s1} and μ_{s2} , for the same B_θ field. As azimuthal information is preserved unaltered in the detection optics, these azimuthal angles will be represented in the partial interference fringes of the Fabry-Perot interferometer (see Fig. 4).

Constraints on the experiment

Various physical effects can broaden the width of the individual spectral peaks. A complete description of the scattering process for electrons in a magnetic field, which includes all the relevant

Fig. 3 Optical magnification of the inclination angle of field lines. The modulated spectrum in the plane perpendicular to the magnetic axis is contained in LOA. For a field line tilted by angle ϵ the modulation is in plane LOA'. The intersection of these planes and the collection aperture is equivalent to the locus of the partial Fabry-Perot fringes. It can be seen how the sensitivity increases with the larger scattering angle.

$$\mathbf{B}_T = \mathbf{B}_\theta + \mathbf{B}_\phi.$$

Fig. 4 Schematic of the experimental arrangement on the DITE tokamak module. The four prisms that collect scattered light from selected positions along the laser beam are shown. Variations in B at different positions z_1 , z_2 and so on along plasma radius correspond to different 'bright-up' positions (r_1, μ_1) , (r_2, μ_2) on the Fabry-Perot fringe pattern.

parameters is not available. As the success of the present experiment rests on the simple theory outlined above, it is sufficient for our purposes to show that the conditions chosen were within its validity range. The relevant constraints are listed below with the experimental values in parenthesis.

(1) The bandwidth of the instrumental profile, obtained from the convolution of the laser line profile and the Fabry-Perot transmission profile, must be much less than the peak spacing

$$\omega_{ce} \approx 3.5 \times 10^{11} \text{ rad s}^{-1}, \Delta\omega_{\text{laser-F-P}} \approx 4 \times 10^{10} \text{ rad s}^{-1}$$

(2) The broadening of the spectral peaks introduced by the range of directions of the magnetic field and incident light must be much less than ω_{ce} . Investigations of this problem^{10,17,18} have shown that if the range of k and B is such that $2\nu_e k \cdot B \lesssim B\omega_{ce}$, the peak broadening is small compared to ω_{ce} . This has been used¹⁶ in calculating the limits imposed on the incident laser beam divergence

$$\beta \lesssim \frac{\omega_{ce}}{2k_0\nu_e}, \left[\frac{\omega_{ce}}{2k_0\nu_e} = 1.7 \text{ mrad}, \beta = 2 \text{ mrad} \right]$$

and the range of field variations in the scattering volume

$$\left| \Delta B_0 - \Delta B_\phi \frac{B_0}{B_\phi} \right| \lesssim \frac{\omega_{ce} B_\phi}{k_0 \nu_e \sin \theta},$$

$$\left[\left| \Delta B_0 - \Delta B_\phi \frac{B_0}{B_\phi} \right| = 5 \text{ mT}, \frac{\omega_{ce} B_\phi}{k_0 \nu_e \sin \theta} = 14 \text{ mT} \right]$$

(3) The electrons must execute a number of complete orbits ($\gtrsim 10$) within the scattering volume; this requires

$$\frac{2\pi r_L}{d_s} \ll 1, \left[\frac{2\pi r_L}{d_s} = 0.04 \right]$$

(d_s = scattering volume thickness)

(4) The dispersed light from the Fabry-Perot etalon must have sufficient intensity and contrast to differentiate experi-

mentally between modulated and unmodulated spectra. This requires the utilisation of as many of the spectral peaks as possible due to the small number of photons per peak. A factor limiting the number of useful peaks available is the range of field intensities¹⁶ within the scattering volume

$$\frac{\Delta B}{B_0} \lesssim \frac{1}{kr_L}, \left[\frac{\Delta B}{B_0} = 2 \times 10^{-3}, \frac{1}{kr_L} = 7 \times 10^{-3} \right]^2$$

When this condition is satisfied the light will be modulated to frequency shifts of at least $k\nu_e$, thus at least 80% of the total intensity of the scattered spectra is deeply modulated.

(5) Long range coulomb collisions suffered by an electron gyrating about a force line can perturb its orbit to such a degree that smearing of the scattered spectrum occurs. The role of collisions has been investigated by several authors¹⁹⁻²¹. According to theory, the effect of collisions becomes serious when the random phase error introduced into the scattered light in one gyro period, becomes a significant fraction of 2π . Because the total phase change experienced by light scattered by a gyrating electron in a gyro-period is typically $kr_L \times 2\pi$, the cumulative effect of many long range coulomb encounters becomes important long before a 90° deflection of the electron has occurred (that is a 'collision'). The various theories can be summarised by stating that the scattered spectrum will be modulated, provided $(kr_L)^2 \nu_e / \omega_{ce} \lesssim \alpha$. For 75% modulation, calculations based on, say, the theory of Farley¹⁹ gives $\alpha = 0.05$, while Peratt's²⁷ calculations suggest $\alpha = 2$ (ν_e is the Spitzer²² electron collisional frequency). Experimental evidence¹¹⁻¹³ shows that the role of collisions has been somewhat overestimated, which suggests values of

$$\alpha > 2, [(kr_L)^2 \nu_e / \omega_{ce} \approx 1 \times 10^{-2}].$$

Scattering experiment on a tokamak

The DITE tokamak²³ was operated in plasma conditions which gave the optimum parameters for detecting the modulated spectrum. Values of electron temperature, plasma density and toroidal field were $T_e \approx 350 \text{ eV}$, $n_e \approx 2 \times 10^{19} \text{ m}^{-3}$, $B = 2 \text{ T}$. The observation time was set at 70 ms from current zero, when there was a low level of X-ray activity and electrical

diagnostics indicated a stable plasma. At this relatively low temperature the number of gyro peaks that need to be superposed is reduced. A nominal scattering angle of 30° was chosen as the best compromise between experimental accuracy and the various smearing effects.

The experimental arrangement is shown in Fig. 4; it includes novel selection optics that utilise a resonant Fabry-Perot-prism combination to provide spatial resolution and high optical efficiency. The laser, interferometer and fringe detection system are mounted on a very stable trolley and the laser input and collection optics and the laser dump are attached to the torus module. The output of an Apollo Q-switched ruby laser (output 10 J in 15 ns) is deflected into the vertical axis by a prism and reduced by an inverted telescope to a parallel 1 cm diameter beam (divergence 1.2 mrad) which passes through the magnetic axis of the tokamak. Stringent measures are taken to keep the stray light level low—by collimating light absorbing baffles on the input and an efficient laser dump. This was necessary, as the detection system was designed to have maximum throughput and is consequently of low contrast. Scattered light is collected through a re-entrant window 75 mm diameter, which is level with the torus wall but 8.5 cm behind the plasma limiter. Situated directly behind the window is an array of four anti-reflection coated prisms, cut so that each takes light from a known scattering volume and the set as a whole produces near paraxial rays on their output faces. A convex lens projects these rays onto a focal plane top. Figure 4 shows how the rays from the outer prisms are more convergent than those from the centre prisms. This difference in angles, with a 15 times expanding telescope, is used to force the light into two predetermined interference fringe orders. Each half of each order then has a spatial correspondence with the scattering volume selected by the prisms. The spatial resolution, ≈ 5 mm, is determined by the back projection of the partial fringe into the scattering column.

The inclination of the field lines varies with radial position. Figure 3 shows how the plane containing the modulated spectra moves across the collection port. It is, therefore, important to position the collection prisms to intercept this plane. An estimate of the position of these planes is made from a nominal B_θ distribution and relies on the relatively large prism ($\pm 15^\circ$) to cover any deviation from this estimated position. Crossed wedge prisms are used to compensate for the displacement of the collection prisms, to ensure the light passes through the focal plane tops.

A 15 nm interference filter is used to isolate the scattered

light before it is matched into the Fabry-Perot. The latter has an effective aperture of 13.5 cm and is dielectrically coated to give 70% reflectivity at 694.3 nm, a finesse of 9, that is, designed for high transmission rather than contrast. The etalon spacing is set to 2.72 mm by optically contacted pads; this matches the free spectral range to the gyro frequency for a 2 T field. (For high stray laser light conditions a high reflectivity coating can be used and the etalon spacers matched to $2\omega_{ce}$ to tune out the 694.3 nm light.) A convex lens focuses the fringe system on the extended red photocathode of a gated (50 ns) image tube RCA 73435 AK. This is fibre optic coupled to a three stage intensifier RCA 8606 which gives a luminous gain of 3×10^5 . A video camera, an EMI intensified Ebitron, is used to record the intensified partial fringes on magnetic tape. The recorded pattern is displayed on a TV monitor for processing. An earlier experiment by Forrest, Muroaka and Peacock²⁴ estimated a basic system sensitivity of 18 photoelectrons per degree of azimuth; the number of scattered photoelectrons here is expected to be 60 to 150 per degree of azimuth.

The first pre-aligned prism array is designed to accept scattered light from the magnetic axis, 6 and 10 cm above the axis. The toroidal field was varied in increments until partial fringes were first observed, indicating the matching condition was satisfied. Three distinct sets of fringes, for example, Fig. 5a, were obtained, while on other shots correlation was necessary to distinguish the 'bright-ups' from noise spots; the stray light was not detectable. To ensure the 'bright-up' spots coincided with the selected Fabry-Perot orders, reference fringes were induced by tapping some light off the laser beam, in lieu of stray laser light. The quality of these was poor due to exposure problems, so they have been drawn in for clarity. As a check the plasma current was reversed; this tilts the field lines and hence the plane containing the modulated light in the opposite direction. In this case, partial fringes were only present from the two prisms looking at the magnetic axis, Fig. 5b. This is as expected, because no prisms were positioned to intercept the tilted planes. As a further test the tokamak was run with both the plasma current and toroidal field reversed, and again the four 'bright-ups' were observed.

To complete a radial scan a second prism array was used; here the prisms were set to look on the magnetic axis and at 4 cm, 15 cm and 21 cm above the axis. Partial fringes were again observed but this time with a different azimuthal, Fig. 5c.

From the video data the azimuthal shifts were related to field inclination angles and as B_θ is known, B_z for each

Fig. 5 Video output data showing intensified partial Fabry-Perot fringes labelled with their spatial correspondence. The circular reference fringes are drawn in for clarity. a, First prism array; b, first prism array with plasma current reversed; c, second prism array, plasma current and toroidal field reversed. The background noise on (a) and (c) has been suppressed by reducing the brightness of the video system.

Fig. 6a The measured poloidal field $B_0(r)$ distribution. b, Comparison of 'q' distributions, \circ from poloidal field measurements and — electron temperature profiles assuming $j \propto T_e^{3/2}$ and constant Z_{eff} in similar plasma conditions.

selected radial position is calculated, Fig. 6a. This profile represents a gas current I of 135 kA, while the measured current was 130 kA.

From this poloidal field distribution, $B_0(r)$, we derive a 'q' profile. This is compared with $q(r)$ calculated from the electron temperature profile obtained by previous scattering measurements under similar plasma conditions, Fig. 6b, where it is assumed the current density $j \propto T_e^{3/2}$ so that

$$q(r) = \frac{2\pi r^2 B_0 \int_0^a T_e^{3/2} r dr}{\mu_0 R I \int_0^a T_e^{3/2} r dr}$$

Accuracy of technique

The purpose of the diagnostic is to measure the magnetic field direction in the toroidal coordinates of the tokamak device.

The field direction is measured in the scattering geometry coordinates and then from the orientation of these with respect to the machine, the magnetic field vector in toroidal coordinates can be calculated. Accuracy in determining the former depends on the sensitivity of the directions of modulated scattered light on the field directions: the greater the scattering angle, the more sensitive the dependency¹⁶. An estimate of the accuracy by which the field direction can be measured is obtained from the product of the sensitivity and the range of scattering directions where the light is modulated. For $\theta = 30^\circ$, $T_e = 350$ eV, the ratio B_θ/B_ϕ can be measured with an accuracy $\Delta(B_\theta/B_\phi) = 0.3\%$. The problem of orientating the laser beam and detection optics to the torus was alleviated by the precision machining of the diagnostic port faces. Before fitting the prism array to the torus, it was set up on a test rig, and back projection of an expanded helium-neon laser beam indicated a spatial accuracy of ± 2 mm in centring the selected scattering volumes. Our measurements depended on the location of the azimuthal position of the partial fringes on a video system. Examination of these basic data, Fig. 5, shows that this is somewhat subjective, but it seems possible to determine the angular positions μ to within 0.4° . This is equivalent to determining the field line inclination to within 0.15° or a $\Delta q < 5\%$, which is close to the basic theoretical accuracy of the method.

Conclusions

Magnetic field profiles can be measured by light scattering from the free electrons in tokamaks causing no perturbation to the plasma medium. Basically the method involves detection of the modulation in the scattered light spectrum due to cycloidal motion of the electrons around the field lines.

The sensitivity of the modulation to the perpendicularity condition ($\mathbf{k} \perp \mathbf{B}_T$) ensures a high degree of accuracy in determining the pitch of the magnetic field line—to within 0.15° .

We have demonstrated a detection system that magnifies small changes in the pitch angle of magnetic field lines. The sensitivity has been optimised by using as large a scattering angle as is consistent with conditions for modulation to be satisfied. It has also been shown that the criteria required to observe modulation, in the present experiments, lie within the validity of simple theory.

An extension of the technique to future tokamaks seems promising.

We thank D. E. Evans, J. Sheffield and J. Katzenstein for their support. The successful application of the technique to tokamaks is due to help from J. Hugill and J. W. M. Paul and the DITE diagnostic and operations group.

The injection of an electron beam into the magnetosphere has been considered a straightforward technique for studying the large-scale structure of the Earth's environment. The large current released in the magnetosphere by the ARAKS experiment has produced many results which are not yet well understood.

ARAKS (Artificial Radiation and Aurora between Kerguelen and Soviet Union) the Franco-Soviet project, was designed to study the injection of an electron beam into the ionosphere and magnetosphere. The first phase was the launch of two Eridan rockets from the Kerguelen Islands (70° 22' W, 49° 35' S) on 26 January and 15 February, 1975. The final stage of each rocket included two complementary experiment systems: an electron gun, indirect potential measuring devices, particle flux detectors, and a cone ejected at a speed of 40 m s⁻¹ from the main payload. This cone carried antennas to detect radio waves generated by the electron beam and its subsequent interaction with the ionosphere. Great efforts were made to have a truly controlled experiment: it was possible to change the energy and intensity of the electron beam, to vary the pitch angle during injection and the relative trajectories of the nose cone and the main payload were accurately determined. This could be accomplished as previous experiments had already yielded extensive results¹⁻³. Many ground-based measurement facilities were set up in conjunction with this experiment, with emphasis on optical and radar measurements in the Northern hemisphere, at the magnetically conjugate point of the Kerguelen Islands as well as on the VLF and VHF measurements at both points.

In addition, Arcas rockets placed parachute deployed X-ray detectors at ~ 80 km above Kerguelen just before each Eridan launch, to verify that there was no large geomagnetic disturbance under way, and again while the electron gun was operating. The X-ray experiment was performed by the University of Houston.

Objectives

The study of the injection of energetic electrons in the upper atmosphere can be divided into three, each subject requiring a different technique of study, although they are complementary from a physical point of view: first, ionisation and visible phenomena (aurora) at the magnetically conjugate point of the

launch site, second, dynamics of injected particles, and third radio waves generated by the electron beam and the effects of wave-particle interactions on the beam itself. A satisfactory compromise was reached between these objectives and the constraints imposed by a space experiment. Two energies were chosen (15 keV and 27 keV) to determine the influence of magnetospheric electrostatic fields on particle trajectories.

Three pitch angles (0°, 70°, 140°) were used to study the following: (1) the production of artificial aurorae and the atmospheric backscattering of the particles at the conjugate point; (2) the magnetic reflection at the mirror point; (3) atmospheric backscattering of the injected electrons in the southern hemisphere.

A variable pulse duration (20ms, 1.28 s, 2.56 s) was adapted in order to have either an accurate definition of the injection angle (20 ms) or a large amount of energy deposited in the atmosphere (2.56 s and a current of 0.5 A).

One of the rockets was fired towards magnetic east in order to compensate for the curvature and gradient drift of reflected electrons in the magnetic field. The other rocket was fired towards the north (26 January), first, in order to reduce the

Fig. 2 Telemetry signal strength (AGC) from the X-ray (ARCAS) and ARAKS (Eridan) payloads. In each case the highest signal is best and the lowest is poor, about half way between these two extremes the signal is unsuitable for the recovery of useful data.

size of the impact area of the beam at the conjugate point and thus to facilitate observation of luminous phenomena, and second to obtain more information from the observation of the beam emission, due to a better trajectory of the cone with respect to the main payload.

We shall emphasise here those results which remain problematic, either in comparison with previous experiments or in relation to theoretical ideas prevailing in this field.

Phenomena observed at the conjugate point

Climatic conditions did not permit definitive observations of the optical effects in the atmosphere: the first launch could not take place during the astronomical twilight, and during the second launch there was some cloud cover. It is, therefore, difficult to draw conclusions and we can only say that the brightness of the artificial aurorae in any case was not brighter than that of a mag 7 star (the TV device's sensitivity permitted the observation of stars down to mag 9).

Artificial aurorae were, however, clearly detected in the magnetically conjugate area by means of pulsed and continuous wave radars operating at 23 and 44 MHz, in the Kostroma and Vologda areas (during the whole first flight and during the last

third part of the second flight). The measurement precision is 2 km in the north-south direction and 10 km in the east-west direction. For the first launch the results agree well with predictions made from the POGO (8/71) and GSFC (12/66) geomagnetic field models. For the second launch, the agreement between the measured and theoretical conjugate point is less satisfactory; however, we note that the magnetic activity index was higher during the second launch ($K_1 = 4$ VS, where $K_1 = 1$ for the first launch).

The variation in distance perpendicular to the line of sight of radar echoes is caused by the lateral movement of the rocket during electron injection. The detailed study of radar echoes coming from the impact of electrons in the neutral atmosphere is more important. We detected the presence of two types of radar echoes, which could be distinguished by a variation in the Doppler effect corresponding to a speed variation from 30 to 200 m s⁻¹. The spectra obtained for the low-velocity component are narrower than the equivalent spectra observed in natural radio aurorae.

The time difference between the onsets of the injection of electrons into the ionosphere at Kerguelen and the onsets of the radar echo at the conjugate is surprising. Figure 1 shows the

Fig. 3 Radio noise at Kerguelen: *a*, 50 and *b*, 75 MHz. The lowest curve represents the current of the injected electron beam.

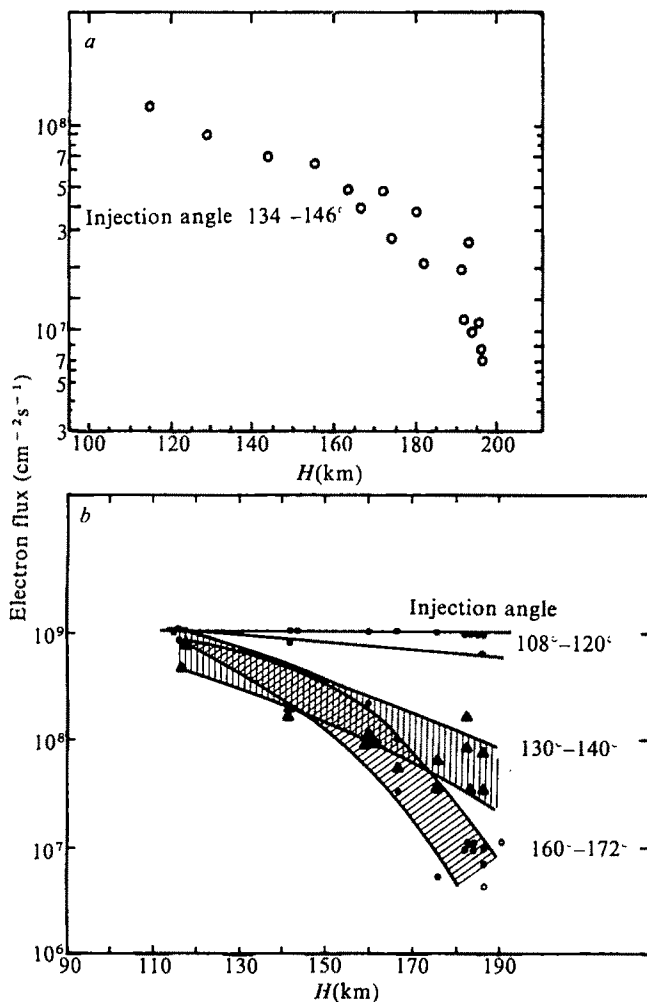

Fig. 4 Electron fluxes ($E > 8$ KeV) observed by the wide angle detectors for downward injections. *a*, 26 January 1975; *b*, 15 February 1975.

scattering of radar echo delays for the first flight for different durations of the gun pulse sequences with specific electrons pitch angle of injection. The calculated time for the transit between conjugate points is 0.65 s for 27 keV electrons, and 0.85 s for 15 keV electrons. Apart from the anomalously high delay times shown in Fig. 1, we also observed that radar echo durations were longer than corresponding gun pulse durations (up to more than 10 s). Both unexpected delays and durations of radar echoes could be due to beam behaviour close to the rocket or beam-plasma interactions along the beam path or ionospheric processes at the conjugate points.

The ejection of electrons without a return current would necessarily carry the main payload, including the gun, to a very high positive potential which would thus eliminate electron emission. When such an injection occurs in a rarefied environment, ionised or not, there exist processes capable of generating these return currents (collection of thermal electrons, ionisation of neutral gas and so on). To facilitate collection of the return currents, two techniques may be used: either to increase the collection surface¹, or to increase the conductivity of the environment by injecting a plasma (Argon plasma was used in the Electron Echo Experiments² and a caesium plasma in ARAKS). This experiment had clearly shown that plasma source causes a large scale disturbance in the payload environment, consequently exerting an influence on gun neutralisation.

The AGC (Automatic Gain Control) of the telemetry signals of the Eridan and Arcas payloads show similar disturbances during the first minute of the active phase of the 26 January ARAKS experiment, although the telemetry frequencies are

quite different (250 MHz and 1.68 GHz) and the two payloads are 80 km apart on the same geomagnetic field line. Figure 2 shows part of these data. A large disturbance occurred in the Eridan signal at about 2 h 39 min 10 s UT when the plasma source was turned on and intensified 1.5 s later when the first long duration gun pulse occurred.

Among the electrons constituting the return current we can distinguish a population on all altitudes having a higher temperature than that of ionospheric plasma (0–300 eV) and another population of energetic electrons (1–3 keV) at higher altitudes (> 120 –130 km). Available data are not sufficient to draw certain conclusions on the rocket potential: ~ 125 V or 1.5–2 kV above 120–130 km; on lower altitudes it is possible to deduce from particle measurements one rocket potential value-definitively $< \sim 100$ V.

The increase of the electron density near the rocket is confirmed by the existence of high frequency radio waves (10–75 MHz) with a wide bandwidth. Figure 3 shows the radio noise data at two frequencies (50 and 75 MHz) detected at Kerguelen when the electron gun was operating. This noise had already been observed in the Zarnitza 1 experiment³; with ARAKS, it was generated in a direction very different from that perpendicular to the magnetic field lines. The measurements should coincide with the presence of a halo around the rocket, visible from the ground when it is at a low altitude. The present results show that the mechanisms of neutralisation, which exist whatever other conditions are involved, are so complex that these observations do not permit a full understanding of them.

Atmospheric electron scattering

Intense electron fluxes ($E > 8$ keV) were observed on the rocket by the wide angle detectors during the gun firings. For downward injection, the measured electron fluxes depend on the pitch angle of injection and on the rocket altitude. The measured fluxes at the same altitude were different for the two flights, perhaps because of large differences in the atmospheric density (Fig. 4). There is a good agreement between the intensities of measured fluxes and the values calculated by a Monte-Carlo method for downward injection. For upward injection, the measured intensities of electron fluxes are several orders of magnitude higher than those calculated by the Monte-Carlo method. Thus it seems that electron scattering by the atmosphere is an important process during downward injection; at present, there is no satisfactory interpretation of the results obtained during upward injections.

Wave particle interactions; wave emission

As expected, the electron beam generates radio waves when penetrating the plasma. Among the various devices used for the

Fig. 5 26 January 1975 H F results. Grey intensity indicates the amplitude of the waves the frequency of which is along the ordinate. The abscissa is the time of the flight and at the bottom the gun sequence is represented.

Table 1 Comparison of Electron echo experiments with ARAKS

	Electron echo experiment 1 ($I = 70$ mA)	Electron echo experiment 2 ($I = 70$ mA)	ARAKS ($I = 0.5$ A)
$f_D < f < f_H$	Wave front $V < 3$ mV	Continuous emission	Wave front $V < 200$ μ V
$f \approx nf_b$	Yes $V < 100$ μ V	Yes	$\omega \approx 4\omega_b$ mainly for the first flight
$f < f_b$	Wave front	Continuous emission $V \approx 300$ μ V	Continuous emission even at $V = 500$ μ V
Low frequency	Wide band noise around the LHR (argon source)		Wide band noise with E and B component (electron gun) Monochromatic electrostatic wave (caesium source) $V \approx 100$ μ V

study of waves generated by the beam, we used for the first time a wide bandwidth telemetry system transmitting a signal waveform up to 5 MHz. Thus we could measure the time evolution of wave spectra with high resolution in the frequency/time domain. It was found in the 0.1–1 MHz range that the time structure of the radio impulse repeats exactly that of the gun impulse, while this is not the case for higher frequency waves.

Figure 5 gives a general representation—analogue to a 'sonagram' of the HF part of the received waves. It must be noted that during the north flight the lateral separation of the nose cone from the beam trajectory varies from 200 m up to 1.5 km. Table 1 summarises the observations comparing them to previous ones². For the frequencies located between the plasma frequency and the upper hybrid frequency the emission due to the gun shows mainly a wave front (Fig. 6) probably due to the coherent part of the spontaneous radiation^{4,5}. In the whistler mode, that is, for frequencies lower than the electron gyrofrequency, ARAKS gives an important result: even at a large distance perpendicular to the beam a continuous radiation is observed. This suggests the existence of some mechanisms by

Fig. 6 *a*, Shape of the electron pulse; *b*, corresponding amplitude of the waves generated close to the plasma frequency in arbitrary units.

which part of the unstable modes trapped in the beam are converted into radiated modes.

For very low frequencies, a very large difference appears during ARAKS which until now has been unexplained: the caesium plasma source generates a quasimonochromatic electrostatic wave (no magnetic component can be detected). The frequency of which changes from 4.5 kHz down to 3.5 kHz. The caesium may have reached the ejectable cone where these measurements were being made.

In conclusion, ARAKS has made a remarkable contribution to plasma physics (discharge of a plasma beam generation of instabilities in an unlimited environment) as well as in geophysics (topography of the geomagnetic fields, analogy with VLF hiss). Some of these points are difficult to explain and we must examine them in detail before claiming that we are really able to perform 'controlled' experiments.

Novel cell cycle control of RNA synthesis in yeast

R. S. S. Fraser* & Paul Nurse

Département de Zoology, University of Edinburgh, West Mains Road, Edinburgh, UK

During the fission yeast cell cycle, the rate of polyadenylated messenger RNA synthesis doubles when the cell reaches a critical size. This size-related control maintains average mRNA content in balance with total cell mass during exponential growth, even in cells growing at different absolute growth rates per cell.

In cell cultures undergoing balanced exponential growth, individual parameters of growth remain at a constant proportion of total cell mass¹. The two daughter cells produced at each division are identical to the parent at the same time in the

preceding cycle: this requires that all cell components are doubled during the course of each cell cycle. The mechanisms controlling the balanced increase of components, and their duplication during each cell cycle are not understood.

A simple model explaining the doubling in amount of a component in each cell cycle can be based on a stepwise doubling in the rate of synthesis of that component at a fixed point in every cell cycle. In the cell cycle of the fission yeast *Schizosaccharomyces pombe* there are periodic doublings in rate of increase of total dry mass², rates of increase in activities of three enzymes³, and in rates of synthesis of total RNA⁴, ribosomal protein⁴, ribosomal RNA⁵ and polyadenylated mRNA⁵. In all cases, the doubling in rate occurs early in the cell cycle.

Two types of control may be proposed to account for the timing of the rate doublings during the cell cycle. The doublings

Table 1 Characteristics of mutant and wild-type strains

	Wild type 972 h ⁻	Mutant <i>wee</i> 1-50
Generation time (min)	140	140
Cell volume at division (μm^3)	149	73
RNA (pg per cell)	3.0 ± 0.04	1.59 ± 0.07 (53%)*
Protein (pg per cell)	12.1 ± 0.3	6.85 ± 0.4 (57%)
PolyA ⁺ mRNA (fg per cell)	23.8 ± 0.8	14.1 ± 0.4 (59%)
DNA (fg per cell)	34.6 ± 1.4	28.4 ± 0.8 (82%)

Cultures of the two strains were grown at 35 °C in phthalate-buffered EMM 2 medium. The length and diameter of 200 cells with cell plates were measured and cell volume calculated. Cell generation time, RNA, protein and DNA contents were determined using cultures in the early phase of exponential growth by methods described in ref. 7. PolyA⁺mRNA content was calculated from the ultraviolet absorption spectrum of polyA⁺mRNA isolated by affinity chromatography on oligo dT-cellulose as described in ref. 5. Polyacrylamide gel electrophoresis of the polyA⁺mRNA fraction showed no contamination by ribosomal or transfer RNAs. Values are means \pm s.e.m.

*Numbers in parentheses give the values of parameters determined in the mutant as a percentage of that determined in the wild type.

might be dependent on DNA replication, which occurs at the beginning of the fission yeast cell cycle⁶. Alternatively, the rate doublings may be related to overall growth, being triggered when the cell reaches some critical size or mass. These two types of control mechanism may be distinguished using strains of fission yeast which have very different cell sizes⁷ but in which there is relatively little variation in the timing of DNA replication in the cell cycle⁷. We have investigated the rates of synthesis of polyadenylated mRNA (polyA⁺mRNA) during the cell cycles of cells dividing at different sizes. Our evidence suggests that the timing of the doubling in rate of polyA⁺mRNA synthesis in the cell cycle is not controlled by the timing of DNA replication, but that doubling in the rate of mRNA synthesis is triggered when the cells reach a critical size. Such a mechanism will maintain the average ratio of polyA⁺mRNA to total cell mass, and will enable cells of different mean sizes to double their mRNA content in each cell cycle.

Characteristics of the wild-type and mutant strains

Table 1 shows generation times and macromolecular contents of exponentially-growing haploid cells of wild type strain 972 h⁻ and a mutant derivative *wee* 1-50 h⁻. The mutant strain (previously described as *cdc* 9-50 (ref. 7)) is altered in the control initiating mitosis, so that mitosis and cell division take place in cells of about half the size of wild type⁷; generation time is unaltered. Growing cells of strain *wee* 1-50 have a reduced macromolecular content per cell, with 57% of the protein, 53% of the total RNA and 59% of the polyA⁺mRNA content of wild type. The average DNA content per cell of *wee* 1-50 is comparatively high, at 82% of wild type. This results in a ratio of polyA⁺mRNA to DNA which is lower in *wee* 1-50 than in wild type, and therefore mRNA content per cell cannot be regulated by gene dosage alone.

Macromolecular synthesis during the cell cycle

To examine the means by which the reduced polyA⁺mRNA content per cell of *wee* 1-50 is brought about, we measured the patterns of synthesis of DNA and polyA⁺mRNA in synchronously-dividing cultures of *wee* 1-50 and wild type. In wild type cells, DNA replication was at the beginning of the cell cycle, almost coincident with cell division (Fig. 1). The rate of incorporation of adenine into polyA⁺mRNA doubled as a step, with the midpoint of the step about 0.1 to 0.2 of a cycle after the midpoint of DNA accumulation. Similar results have been obtained using ³H-uridine as label instead of ³H-adenine, and also with another strain of wild-type size⁵.

Fig. 1 Changes in cell no., DNA content and rates of adenine uptake and polyA⁺mRNA synthesis in a synchronously-dividing culture of *Schizosaccharomyces pombe* Lindner, wild-type strain 972 h⁻. Cells were collected by filtration from a population growing exponentially at 35 °C in phthalate-buffered EMM2 medium⁷, and were fractionated by sedimentation rate centrifugation through a lactose density gradient¹⁷ (MSE Type A zonal rotor). Small cells at the beginning of the cell cycle were selected as inoculum for the synchronous culture. Changes in cell number were monitored using a Coulter counter. Samples of 50–100 ml culture were withdrawn every 20 min and pulse-labelled by incubating for 10 min (0.07 of the cell generation time) with 2.5 $\mu\text{Ci ml}^{-1}$ [³H]adenine (Radiochemical Centre). The total adenine concentration of the pulse medium was adjusted to 1 $\mu\text{g ml}^{-1}$ by addition of nonradioactive adenine. Less than 10% of the radioactivity supplied was taken up during the pulse. DNA content and rates of adenine uptake and polyA⁺mRNA synthesis were measured as described in ref. 5. Values for polyA⁺mRNA synthesis are means \pm s.e.m. of six determinations. The midpoints of the two successive doublings in cell numbers fix stages 0 and 1 on the cell cycle map. The midpoints of the stepwise doublings in DNA content and rate of polyA⁺mRNA synthesis were taken as the time when the step attained the value midway between the two plateaus on either side of the step, and are marked by vertical bars. ●, Cell no.; □, DNA content; △, rate of adenine uptake; ○, rate of polyA⁺mRNA synthesis.

Quite different results were obtained with synchronous cultures of *wee* 1-50. The midpoint of DNA replication was 0.2 to 0.3 of a cycle after cell division (Fig. 2), consistent with previous results⁷ and with the average DNA content of *wee* 1-50 cells in asynchronous culture being 82% of that of wild type (Table 1). The rate of adenine incorporation into polyA⁺mRNA also doubled as a step, but the midpoint of the step was at an

Fig. 2 Changes in cell no., DNA content and rates of adenine uptake and polyA⁺mRNA synthesis in a synchronously-dividing culture of the mutant strain *wee* 1-50. Measurements were made and the cell cycle stage of changes derived as explained in the legend to Fig. 1. ●, Cell no.; □, DNA content; △, rate of adenine uptake; ○, rate of polyA⁺mRNA synthesis.

Table 2 PolyA⁺mRNA synthesis during the cell cycles of wild type and *wee 1-50* mutant strains

	Wild type 972 h ⁻¹	Mutant <i>wee 1-50</i>
Cell cycle stage of midpoint of stepwise doubling in rate of polyA ⁺ mRNA synthesis	0.11 ± 0.04	0.81 ± 0.06
Rate of polyA ⁺ mRNA synthesis per cell before stepwise rate-doubling (10 ³ × c.p.m.)	1.24 ± 0.05	1.29 ± 0.03
Rate of polyA ⁺ mRNA synthesis per cell after stepwise rate-doubling (10 ³ × c.p.m.)	2.43 ± 0.15	2.39 ± 0.14

Data were derived from synchronous culture experiments such as shown in Figs 1 and 2. The time of the midpoint of stepwise doubling in rate of polyA⁺mRNA synthesis was expressed as stage in the cell cycle as shown in Fig. 1. Rates of polyA⁺mRNA synthesis per cell before and after the stepwise doubling in rate were calculated by dividing the steady rates of incorporation before and after the step by the cell number per ml after separation of the daughter cells formed at the beginning of that cell cycle. Values are means ± s.e.m.

average of 0.81 of the cell cycle (Table 2). This is 0.5 of a cycle later than DNA replication in *wee 1-50*, and 0.7 of a cycle later than the corresponding step in rate of incorporation into polyA⁺mRNA in wild type. These results suggest that the timing of the doubling in rate of incorporation into polyA⁺mRNA is not directly controlled by the timing of DNA replication.

The pattern of increase in the rate of adenine uptake during growth of synchronous cultures is rather variable (Figs 1 and 2, and ref. 5). However, the stepwise increases in the rate of adenine incorporation into polyA⁺mRNA were greater than any periodic changes in adenine uptake. This suggests that the changes in rate of adenine incorporation into polyA⁺mRNA resulted from changes in rate of synthesis and not from changes in rate of precursor uptake. Control experiments were carried out to check whether the doublings in rate of polyA⁺mRNA synthesis were merely periodic fluctuations induced by the physiological trauma of synchronous culture preparation. Cells from the parent culture were exposed to all the conditions used to prepare synchronous cultures, but the inoculum selected contained cells at all stages of the cell cycle. The resulting culture showed an exponential, asynchronous increase in cell number. The rate of adenine incorporation into polyA⁺mRNA also increased continuously with time: there was no suggestion of the steps in rate of incorporation seen in synchronous culture. We conclude that the stepwise doublings in rate of polyA⁺mRNA synthesis observed in synchronous cultures were cell cycle-related events.

Dependency on DNA replication

Although in the cell cycle of *wee 1-50* the timing of the doubling in rate of synthesis of polyA⁺mRNA is not closely linked with the timing of DNA replication, the doubling in rate of polyA⁺mRNA synthesis might still depend on completion of the previous round of DNA replication. We examined this possibility by following the rate of synthesis of polyA⁺mRNA in an asynchronous, exponentially-growing culture of *wee 1-50* after inhibition of DNA synthesis by hydroxyurea. The rate of DNA synthesis fell to about one quarter of its initial level within 5 min of addition of the inhibitor (Fig. 3). The rate of synthesis of polyA⁺mRNA continued to increase at approximately the same rate as in the control for about 70 min, then the rate became constant. This 70-min delay is similar to the period between DNA replication and doubling in rate of polyA⁺mRNA synthesis in synchronously-dividing cultures of *wee 1-50* (Fig. 2). These results fit the following model: the doubling in rate of synthesis of polyA⁺mRNA is dependent on the occurrence of

the preceding round of DNA replication. After DNA replication, a cell is potentially capable of doubling its rate of polyA⁺mRNA synthesis, but in *wee 1-50* does not do so until 0.5 of a cycle later (Fig. 2, Table 2). In an asynchronous population, there will be a fraction of cells which have completed DNA replication but which have yet to double their rate of polyA⁺mRNA synthesis. These cells are responsible for the 70-min period during which the rate of polyA⁺mRNA synthesis rose after inhibition of DNA synthesis (Fig. 3). Consistent with this interpretation, in cells of wild type size, where doubling in rate of polyA⁺mRNA synthesis follows closely on DNA replication (Fig. 1, Table 2), hydroxyurea added to an asynchronous culture causes the rate of polyA⁺mRNA synthesis to become constant within 10 to 20 min (ref. 5).

Hydroxyurea is the only inhibitor of yeast DNA synthesis known to give the very rapid inhibition required for these experiments⁸. Its use is open to the criticism that hydroxyurea reportedly inhibits precursor uptake and growth (ref. 8 and J. M. Mitchison and J. Creanor, unpublished). Adenine uptake was not inhibited in our experiments (Fig. 3), but we cannot entirely exclude the possibility that hydroxyurea was having some unknown side effect which prevented further rise in the rate of polyA⁺mRNA synthesis.

Explanation for the reduced polyA⁺mRNA content of *wee 1-50*

We have shown that the rate of polyA⁺mRNA synthesis doubles much later in the cell cycle of *wee 1-50* than in wild type. This difference can be shown to be sufficient to account for the

Fig. 3 Changes in rates of DNA synthesis, adenine uptake and polyA⁺mRNA synthesis in a culture of *wee 1-50* after inhibition of DNA synthesis. An exponentially-growing culture containing 10⁶ cells ml⁻¹ was split in two. Hydroxyurea (11 mM) was added to one half at 0 min to inhibit DNA synthesis. The other half served as control. The rate of DNA synthesis was measured as described in ref. 18. Rates of adenine uptake and polyA⁺mRNA synthesis were measured as described in the legend to Fig. 1. *a*, DNA synthesis; *b*, rate of adenine uptake; *c*, rate of polyA⁺mRNA synthesis. Open symbols represent values for the control culture, closed symbols for the hydroxyurea-treated culture.

Fig. 4 Relationship between cell protein content and cell-cycle time of the stepwise doubling in rate of polyA⁺mRNA synthesis, in yeast strains of a wide range of sizes. Each open circle represents the midpoint of a stepwise doubling in rate of polyA⁺mRNA synthesis, measured in synchronous cultures as shown in Fig. 1. Closed circles represent the mean values for each strain. The yeast strains used were 972 wild-type haploid (+); strain 132 haploid (132); 972 diploid wild type (+/+); *wee* 1-50 haploid (1-50); *wee* 1-50 diploid (1-50/1-50) and the heterozygous diploid of *wee* 1-50 and 972 wild type (+/1-50). The cell-cycle time scale is the time between the midpoints of two successive divisions. The points for time of doubling in rate of polyA⁺mRNA synthesis are plotted along a line showing the increase in protein content during the cell cycle for each strain. These lines were calculated from the mean protein content per cell in asynchronous, exponential culture for each of the strains knowing that protein content per cell increases close to exponentially during the cell cycle⁹. The protein per cell data for the three diploid lines have been divided by two to permit comparison with the haploid lines.

reduced polyA⁺mRNA content of the average *wee* 1-50 cell in exponential culture (Table 1), by calculating the polyA⁺mRNA content of *wee* 1-50 if the delay in doubling were the only difference between the two strains. The absolute rates of polyA⁺mRNA synthesis per cell before and after the step doubling in rate are the same for *wee* 1-50 and wild type (Table 2). We assume that the half life of the polyA⁺mRNA is the same in both strains. In these conditions, the mean polyA⁺mRNA content of *wee* 1-50 cells in asynchronous, exponential growth is 2^{-l} of the wild-type content, where l is the delay, as a fraction of the cell cycle, between doubling in rate of polyA⁺mRNA synthesis in the two strains. The derivation of this relationship is to be described in detail elsewhere (A. Barnes, P.N. and R.S.S.F., in preparation). The average delay between doubling of the rate of polyA⁺mRNA synthesis in wild type and *wee* 1-50 was 0.70 of the cell cycle (Table 2). This gives a calculated value for mean polyA⁺mRNA content of *wee* 1-50 cells of 62% of the wild-type content. This is in good agreement with the observed value of 59% (Table 1), and indicates that the delay in doubling the rate of polyA⁺mRNA synthesis in *wee* 1-50 cells is sufficient to explain their reduced polyA⁺mRNA content.

Cell size control over polyA⁺mRNA synthesis

We now consider the nature of the mechanism which determines that the rate of polyA⁺mRNA synthesis doubles early in the cell cycle of wild type and late in the cycle of *wee* 1-50. *Wee* 1-50 cells at the end of their cycle are similar in size to wild-type cells at the beginning of their cycle, suggesting that some aspect of cell size might be important. We have studied this quantitatively by taking cell protein content as a measure of size. Knowing the protein content per cell in asynchronous, exponential culture (Table 1), and that protein per cell increases close to exponentially through the cell cycle⁹, we can calculate changes in protein per cell during the cell cycle of each strain. Figure 4 shows that in *wee* 1-50 and wild type, the doubling in rate of

polyA⁺mRNA synthesis occurred in cells with similar protein contents. To examine this further, we have measured the time when the rate of polyA⁺mRNA synthesis doubles in another haploid strain (132) of wild-type size⁵, and in a series of diploid strains of different sizes. All strains investigated showed a stepwise doubling in the rate of polyA⁺mRNA synthesis in synchronous culture; all have similar mean generation times. The protein contents of the diploid strains have been divided by two before plotting (Fig. 4), to allow comparison directly with the haploid strains.

In the six strains, the times at which the rate of polyA⁺mRNA synthesis doubles are distributed throughout the cell cycle. However, all strains double their rates of polyA⁺mRNA synthesis when the cells have very similar levels of protein per haploid genome (Fig. 4). This suggests a cell size-related control over the timing of the doubling in rate of polyA⁺mRNA synthesis in the cell cycle.

We propose that in cells in steady-state growth, the rate of synthesis of the majority of polyadenylated mRNAs is under a general control. This sets the rate per cell at one of two levels, the higher rate being double the lower. The cell switches from the lower to the higher rate on attaining a critical size or mass. The control consists of two parts: the recognition of the threshold size, and the means by which the rate of polyA⁺mRNA synthesis is maintained at the two discrete levels.

Recognition of the threshold cell size might involve monitoring some aspect of cell growth. Such size-monitoring mechanisms have been proposed as controls of initiation of DNA replication and mitosis¹⁰. An example would be the 'inhibitor dilution' model as proposed by Pritchard¹¹. A regulator of mRNA synthesis would be synthesised as a pulse once per cycle. When the concentration of this regulator is reduced to a threshold value by increase in cell volume, the doubling in rate of polyA⁺mRNA synthesis would be effected. Our comparison of haploid and diploid strains suggests that the amount of regulator synthesised would be a constant amount per haploid genome, not a constant amount per cell. We do not know the nature of this regulator, but a promising candidate would be a molecule analogous to 'magic spot' which is involved in a stringent type of control¹².

The simplest mechanism whereby the rate of mRNA synthesis could be maintained at one rate or twice that rate is one based on a modification of the gene dosage model. This type of model is supported by our experiments on the rate of polyA⁺mRNA synthesis after inhibition of DNA accumulation by hydroxyurea (Fig. 3), and by the observation that the absolute rates of polyA⁺mRNA synthesis per cell before and after the step doubling are the same in *wee* 1-50 and wild type (Table 2). However, since the doubling in rate of polyA⁺mRNA synthesis may occur much later than DNA replication, as in *wee* 1-50, there must be some further mechanism to maintain the rate of polyA⁺mRNA synthesis at the pre-replication rate until the threshold cell size is reached. This could involve some form of temporary masking of one of the two copies of each gene present after replication^{3,13-15}, only one of which would be active until the cell had attained the threshold size. Alternatively, there could be some form of gene dosage compensation such as is found in *Drosophila*¹⁶. In this model the rate of transcription of each of the two gene copies present after DNA replication would be half that of the single copy present before replication. The rate of transcription of both copies would be doubled when the cell attained the threshold size. This control could act through the availability of RNA polymerase or its regulatory subunits, though in these cases it is not clear why the rate of transcription should necessarily double as a step.

The proposed general control over rate of mRNA synthesis does not exclude the possibility that the rate of transcription of individual genes is also subject to other, more specific controls.

Significance of cell size control

The cell size-related control over time of doubling in rate of polyA⁺mRNA synthesis has several implications for the control

of balanced exponential growth. It will maintain the average polyA⁺mRNA content per cell as a constant proportion of total cell mass during exponential growth, and will ensure that polyA⁺mRNA content per cell doubles over the course of each cell cycle. This regulation of balanced growth and duplication will operate even in cells dividing at different sizes and growing at different absolute growth rates per cell. Thus the control could maintain the concentration of polyA⁺mRNA within a range suitable for further post-transcriptional modulation.

It has been shown⁶ that a doubling in the rate of mRNA synthesis in each cell cycle could lead to observed patterns of accumulation and doubling of certain enzymes in each cell cycle³. A cell size-related control over the time of doubling in rate of mRNA synthesis therefore offers the possibility of a widespread regulation of the synthesis of those enzymes not subject to specific controls at the transcriptional or translational levels.

letters to nature

Intensity of interstellar Lyman alpha

TARAFDAR and Wickramasinghe¹ suggested that the Lyman alpha (L α) intensity in the interstellar medium may be in the range $(1-4) \times 10^{-4}$ erg cm⁻² s⁻¹ sr⁻¹ and have pointed out that, if this is the case, L α may play an important part in photoemission from interstellar grains. Here we argue that typical L α intensities in interstellar H I are significantly less than 1×10^{-4} erg cm⁻² s⁻¹ sr⁻¹, considering three principal sources: photoionised H II regions; shock-heated gas; and collisional excitation and recombination in interstellar H I.

Approximately 50% of O stars and 80% of B0–B5 stars have, at any moment, escaped from their native cloud complex and generate diffuse ($n_e < 1$ cm⁻³) H II regions, and are estimated to emit H-ionising photons at a rate, projected onto the galactic disk, of 6.9×10^6 cm⁻² s⁻¹ in the solar neighbourhood², consistent with the galactic H α background³ if interpreted as recombination radiation⁴. If 0.7 L α photons result from each H recombination to level $n \geq 2$, then L α photons are generated in diffuse H II regions and injected into H I at a rate, projected onto the disk, of

$$j_{\alpha}(\text{H II}) = 5 \times 10^6 f_{\text{H II}} \text{ cm}^{-2} \text{ s}^{-1}, \quad (1)$$

where $f_{\text{H II}}$ is the fraction of L α photons which escape absorption by grains within the H II.

Shock-heated gas resulting from cloud–cloud collisions or supernova (SN) blastwaves will emit L α . If supernovae occur (in a 15 kpc disk) at a rate S , and a fraction ϵ of the initial energy E_0 per SN is converted, within the SN remnant (SNR), to L α , then the L α injection rate per disk area is

$$j_{\alpha}(\text{SN}) = 2.9 \times 10^6 \left(\frac{\epsilon}{0.2} \right) \left(\frac{S}{0.05 \text{ yr}^{-1}} \right) \left(\frac{E_0}{10^{51} \text{ erg}} \right) f_{\text{SN}} \text{ cm}^{-2} \text{ s}^{-1} \quad (2)$$

where f_{SN} is the fraction of L α which escapes absorption within the SNR. From Tamman's⁵ values for the total SN rate we estimate $S \leq 0.05 \text{ yr}^{-1}$ for the rate within the disk. The optically thin plasma in the interior of the SNR with $T > 10^5 \text{ K}$ contributes less than 0.01 to ϵ . If the ambient medium is initially neutral and then collisionally ionised by the blastwave shock, an appreciable number ϕ of L α photons per shocked H atom are emitted for shock speeds $v_s \gtrsim 40 \text{ km s}^{-1}$. Assuming initially neutral solar composition gas, Table 1 gives v_s and ϕ as a function of the shock temperature T_s .

Numerical models of SN blastwaves⁶ may be approximated by

the Sedov solution for $v_s \geq v_a$, an abrupt drop of v_s from v_a to v_b , and subsequent evolution with radius $r_s \propto t^{1/3}$. One then estimates, assuming $v_a = 200 \text{ km s}^{-1}$ and $v_b = 140 \text{ km s}^{-1}$,

$$\epsilon \approx 0.0237 \left(\frac{v_a}{200 \text{ km s}^{-1}} \right)^{-2} \left\{ 2v_a^2 \int_{v_a}^{\infty} v_s^{-3} \phi dv_s + v_b \int_0^{v_b} v_s^{-2} \phi dv_s \right\} \approx 0.17 \quad (3)$$

If the blastwave propagates into pre-ionised material ϵ will be much smaller. If $\epsilon \leq 0.2$ and $E_0 \leq 10^{51} \text{ erg}$, then

$$j_{\alpha}(\text{SN}) \leq 3 \times 10^6 f_{\text{SN}} \text{ cm}^{-2} \text{ s}^{-1} \quad (4)$$

Further conversion of SN energy to L α , by X-rays emitted (and cosmic rays accelerated) by the SNR will be included in $j_{\alpha}(\text{H I})$ below.

Either excitation by nonthermal particles or radiative recombination can produce L α in H I. For ionisation by either 100 eV X-rays⁷ or 2 MeV protons⁸ the number β of L α photons collisionally excited per H ionisation (both primary and secondary) can be estimated to be $\beta \approx 1.5$. The L α generation rate per volume is $(\beta + 0.7)n_H \xi$, where ξ is the total (primary and secondary) ionisation rate for H atoms due to either cosmic rays or soft X-rays; projected onto the plane this is

$$j_{\alpha}(\text{H I}) = 1.3 \times 10^6 \left(\frac{N_H}{6 \times 10^{20} \text{ cm}^{-2}} \right) \left(\frac{\langle \xi \rangle}{10^{-15} \text{ s}^{-1}} \right) \text{ cm}^{-2} \text{ s}^{-1} \quad (5)$$

where N_H is the full-thickness H I column density normal to the plane. As the average $\langle \xi \rangle$ is almost certainly less than 10^{-15} s^{-1} , and $N_H \approx 6 \times 10^{20} \text{ cm}^{-2}$ (ref. 9), evidently $j_{\alpha}(\text{H I}) < 1.3 \times 10^6 \text{ cm}^{-2} \text{ s}^{-1}$.

Table 1 The number ϕ of L α photons per shocked H atom

$T_s(\text{K})$	$v_s(\text{km s}^{-1})$	ϕ	$T_s(\text{K})$	$v_s(\text{km s}^{-1})$	ϕ
5×10^6	416	1.1	1.5×10^5	72	2.6
2×10^6	263	1.1	1×10^5	59	1.8
1×10^6	186	1.3	7×10^4	49	1.2
7×10^5	156	1.4	5×10^4	42	0.86
5×10^5	132	1.7	3×10^4	32	0.44
3×10^5	102	2.8	2.5×10^4	29	0.34
2.5×10^5	93	4.2	2×10^4	26	0.23
2×10^5	83	3.4	1.5×10^4	23	0.12

From equations (1), (4) and (5) the total $L\alpha$ injection rate into H I is

$$j_{\alpha}(\text{total}) < 10 \times 10^6 \text{ cm}^{-2} \text{ s}^{-1} \quad (6)$$

It will be argued that $f_{\text{H I}} \approx 0.6$, so that the inequality in equation (6) seems reasonably secure. Assuming no escape from the disk; $N_{\text{H}} = 6 \times 10^{20} \text{ cm}^{-2}$; a grain absorption cross section per H nucleus $\sigma = 0.7 \times 10^{-21} \text{ cm}^2$ at $\lambda = 1,215 \text{ \AA}$ (refs 10–12), the mean $L\alpha$ intensity is estimated from equation (6) to be

$$\langle I_{\alpha} \rangle = \frac{h\nu j_{\alpha}}{4\pi n_{\text{H}} \sigma} \text{ sr}^{-1} < 3.1 \times 10^{-5} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \quad (7)$$

or less than 1.9×10^6 photons $\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$. The continuum background near 10.2 eV has been estimated^{13,14} to be about 1.9×10^6 photons $\text{cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ eV}^{-1}$, so that $\langle I_{\alpha} \rangle$ is at most comparable to the ultraviolet continuum in a 1 eV band centred on 10.2 eV.

Having estimated the mean $L\alpha$ intensity, we investigate its spatial variation. As seen above, $\sim 50\%$ of the $L\alpha$ generation occurs in diffuse H II regions, so consider, as a typical example, the Strömgren sphere surrounding an O7 V star emitting $N_{\text{e}} = 7.2 \times 10^{48}$ H-ionising photons s^{-1} (ref. 15) in a cloudless medium with $n_{\text{H}} = 0.5 \text{ cm}^{-3}$, $T = 8,000 \text{ K}$, and dust absorption cross section/H $1.1 \times 10^{-21} \text{ cm}^2$ and $0.7 \times 10^{-21} \text{ cm}^2$ for Lyman continuum and $L\alpha$, respectively. For a dusty Strömgren sphere¹⁶ the radius at which $n(\text{H}^+) = n(\text{H}^0)$ is $R_{1/2} \approx 87 \text{ pc}$, the $L\alpha$ optical depth (from $r = 0$ to $r = R_{1/2}$) at line centre is 9×10^4 , while the $L\alpha$ optical depth in dust is 0.094. Formulae fitted¹⁷ to numerical calculations predict an escape probability $f_{\text{H I}} \approx 0.57$ and a typical frequency shift for the escaping photons of ~ 4.0 Doppler widths $= 46 \text{ km s}^{-1}$. In the surrounding H I the escaping photons are on the extreme Lorentz wing, have a mean free path $= 0.26$ ($\text{cm}^{-3}/n_{\text{H}}$) pc, scatter about 1,800 times before being absorbed, and diffuse about $0.52(1,800)^{1/2}$ pc away from the boundary of the H II region. The mean $L\alpha$ intensity in this zone of thickness $\Delta R = 22 \text{ pc}$ is

$$I_{\alpha} \approx \frac{0.7 f_{\text{H I}} N_{\text{e}} h\nu}{16\pi^2 n_{\text{H}} \sigma R_{1/2}^2 \Delta R} \approx 3.0 \times 10^{-4} f_{\text{H I}} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \quad (8)$$

The leading dependence of I_{α} is $I_{\alpha} \propto f_{\text{H I}} n_{\text{H}}^{4/3} N_{\text{e}}^{1/3}$. As a second example consider a spherical SNR with $E_0 = 10^{51} \text{ erg}$ in a medium with $n_{\text{H}} = 0.5 \text{ cm}^{-3}$ and with shock speed $v_s = 100 \text{ km s}^{-1}$ (and radius $R \approx 33 \text{ pc}$ (ref. 6)); similar estimates lead to an average $L\alpha$ intensity $I_{\alpha} \approx 2 \times 10^{-4} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$ in a 35 pc thick shell surrounding the SNR.

The following conclusions are reached. First, the mean $L\alpha$ intensity in galactic H I is at most about $3 \times 10^{-5} \text{ erg cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1}$. Second, the $L\alpha$ energy density due to H II regions and supernovae is very patchy, varying over length scales of $\sim 10 \text{ pc}$ or so. Third, within zones of enhanced $L\alpha$ (perhaps 10% of galactic H I) surrounding supernovae and H II regions the $L\alpha$ intensity may be large compared to the continuum background in the 10.2–13.6 eV band. Finally, in most galactic H I the energy density of $L\alpha$ is small compared to that of continuum ultraviolet.

Search for high energy γ -ray bursts from evaporation of primordial black holes

PRIMORDIAL black holes (PBH) have been predicted by Hawking¹. Density fluctuations in an early Universe might have given rise to a power law spectrum of low mass black holes which would evaporate by a thermal radiation process. Holes of initial mass $< 10^{12} \text{ kg}$ formed at the beginning of the Universe would have evaporated by now. However, holes of initial mass $> 10^{12} \text{ kg}$ might now be entering the terminal stages of evaporation, culminating in an explosion. The total energy liberated in particle emission and the corresponding radiation time scales depend critically on the nuclear models adopted². The composite particle (CP) model predicts the liberation of 10^{27} J during the final 10^{-7} s of the explosion. About 10% of the total energy goes into γ rays with the spectrum peaked at 250 MeV. The elementary particle (EP) model predicts the liberation of 10^{30} photons during the final 0.1 s of the explosion at energies around $5 \times 10^{12} \text{ eV}$ (refs 3, 4). We report here the results of a search for γ rays associated with the evaporation of PBHs, and upper limits are presented based on the latter model.

Two ground based extensive air shower detection systems, separated by 250 km, have operated in time coincidence since January 1975. The detection systems have been described in detail elsewhere^{5,6}. Four scintillation counters are used at each station to detect showers. The counter thresholds are set at the single particle level. The outputs of the four individual detectors are added together to give an event rate which varies between 780 and 820 s^{-1} , at each station. Such events are termed singles. Threshold measurements show that for this mode 50% of the showers are in the energy range $1.5\text{--}9 \times 10^{13} \text{ eV}$. In addition, at each station, coincident combinations of at least two out of the four counters are formed, giving a rate of typically 3 s^{-1} . Such events are termed multiple, with corresponding shower energies in the range $7\text{--}20 \times 10^{13} \text{ eV}$.

Overflow scalars individually monitor the single and multiple event rates over a range of time scales. If the preset count is exceeded during any sampling interval, the absolute time of occurrence is recorded to an accuracy of 10^{-3} s . Details of the preset levels and associated sampling intervals are shown in Table 1. Event timing is accomplished by a 10 kHz waveform, derived from a 5 MHz oven controlled crystal and fed to a 7-decade digital logic scalar with latch facilities. Absolute time from the 60 kHz MSF Rugby transmission is injected into the system each hour to produce an absolute time marker. For each event, 32 bits of timing and coding information are stored in a 1,024-bit buffer memory. The overall writing time for any event into the memory is 8 μs . On completion of storage of the 32nd event, a readout sequence is initiated and the buffer contents are punched on paper tape. The total readout time is 5 s, which represents the system dead time per buffer of 32 events. Both stations have accumulated data almost continuously since January 1975.

The analysis procedure adopted has involved a computer search of the tape records containing the coded events recorded at each station. Tests with artificial events injected simultaneously at both stations showed that both the hardware and software functioned as designed. Because of the systems threshold energy for shower detection, our observational data can only test the EP model as a possible mechanism for the production of exploding PBHs. We make the assumption that any PBH close enough to Earth will produce a flux of high energy γ rays at the top of the

Table 1 Results of an average 24-h observation

Sampling time interval	Preset count level	Event code type	Event classification	Predicted rate (d^{-1})	Average observed rate (d^{-1})
10^{-2} s	26	2	Single	2.9	3
10^{-1} s	124	3	Single	2.5	2
1 s	12	5	Multiple	6.1	5

Table 2 Upper limits for different characteristic time scales

Code pair	Coincidence resolving time (τ) (s)	Total search time (T) (d)	No. of coincidences observed in time $T(N_o)$	No. of coincidences predicted on a random basis in time $T(N_r)$	Upper limit to the detectable γ -ray burst rate per year (N_b)	Upper limit to the rate of PBH explosions per unit volume (N_{exp}) ($\text{pc}^{-3} \text{yr}^{-1}$)
(2-2)	10^{-2}	802	0	0.0005	2.1	4.8×10^3
(3-3)	10^{-1}	802	0	0.05	2.1	1.9×10^4
(5-5)	1	821	0	0.3	2.0	6×10^3

atmosphere which in turn initiates cascades of showers of basically the same temporal characteristics at the two stations. Such considerations dictate that in the analysis, no cross coded coincidences (Table 1) should be looked at. The choice of coincidence resolving time is determined by the predicted characteristic time of the radiation burst for the EP model, 0.1 s. In view of the probable uncertainties in this model, however, we have looked for coincidences between like coded events in the range of time scales from 0.01–1 s. Table 2 summarises the results of this analysis. It tabulates both the observed (N_o) and random (N_r) expectation rates for different resolving times (τ) pertaining to total search times (T).

The number of observed coincidences (N_o) was used to calculate upper limits, at the 99% confidence limit, of the detectable γ -ray burst rate (N_b) for the different resolving times (τ). Based on the EP model, upper limits to the density of PBH explosions (N_{exp}) within the sensitive volume of the detectors field of view have been determined as follows.

The model predicts the emission of 10^{30} photons at energies around 5×10^{12} eV. In view of uncertainties in the model and for the calculation we assume that these 10^{30} photons will be detectable within both ranges of energy resolution of the detection systems. The shower collection areas appropriate to both these energy ranges are 1,000 m² for the multiple coded events and 2,500 m² for those coded as singles. The larger collection area in the lower energy band reflects a lower particle density requirement in the detector trigger system. The field of view of each stations detection system is estimated to be 1 sr. As an example, consider the estimation of (N_{exp}) for a code 5 coincidence where on average the trigger requirements at each station demand an excess of 9 counts per s. The maximum distance to which an exploding PBH would still remain detectable would be a radius of 3×10^{15} m. The corresponding sensitive volume within the field of view is $3.3 \times 10^{-4} \text{pc}^3$; hence, for an upper limit of 2.0 bursts yr^{-1} , we estimate an upper limit to the number of explosions (N_{exp}) of $6 \times 10^3 \text{PBH pc}^{-3} \text{yr}^{-1}$. Values of (N_{exp}) for the other time scales τ are given in Table 2.

A significantly better upper limit to the rate of explosion of PBHs leading to γ -ray bursts has been given by Porter and Weekes^{7,8} but this is based on the CP model in which 10^{27} J is released in the explosion. More recently, Rees⁹ has suggested that if PBHs exist and if they emit particles, then they might be detectable indirectly from radio and optical emission arising from the interaction of the charged particles with the ambient interstellar magnetic fields. Upper limits to the possible pulsed radio emission based on Rees have been given by Jelley *et al.*¹⁰ while Porter and Weekes¹¹ quote limits to the rate of emission of optical pulses.

Indentation hardness and semiconductor-metal transition of germanium and silicon

A HARD indenter pressed into the surface of a ductile solid such as a metal will produce a permanent indentation. The mean pressure over the indentation is known as the hardness of the solid and is a measure of its yield or flow stress¹. With many relatively brittle materials such as glass and rock salt, it is possible to form plastic indentations at low loads. This is because the indentation process involves a very large component of hydrostatic stress which inhibits brittle failure: the material then yields by flow and the hardness is again a measure of the (ductile) yield stress of the solid²⁻⁴. At high loads the indentation is usually accompanied by appreciable cracking. Crack-free hardness indentations may also be made at low loads in single crystals of germanium and silicon (C. A. Brookes and our unpublished data) and it is suggested here that this may be due at least in part, to a different mechanism.

Germanium has fourfold coordination and is a semiconductor. Under a hydrostatic pressure of approximately 115–120 kbar the crystal structure changes: there is six-fold coordination and the germanium becomes metallic⁵. Shimomura *et al.*⁶ give the transition pressure for polycrystalline germanium as 100 kbar. We now note that the indentation hardness of germanium, although somewhat dependent on crystal face and indenter orientation, is of order 800 kg mm⁻², that is, 80 kbar, which is comparable with the transition pressure. Silicon shows a similar behaviour. The semiconductor-metal transition occurs at a pressure of 190 kbar (ref. 5) or for polycrystalline silicon, 155 kbar (ref. 6); the indentation hardness is of order 120 kbar. Thus both the transition pressure and the hardness value are again comparable and are about 50% greater for silicon than for germanium.

We may now consider the corresponding behaviour of diamond. Hardness indentations may be made, though they are always apparently accompanied by some cracking. The hardness value is of order 10,000 kg mm⁻², suggesting a metallic transition at a pressure of about 1,000 kbar. Such a conclusion is supported by direct observations on the metallic transition of diamond by Vereshchagin *et al.*⁷. These results suggest that the indentation hardness is indeed close to the semiconductor-metallic transition pressure and that under conditions of hardness measurements, the material around the indenter becomes sufficiently ductile to sustain plastic flow.

Table 1 Correlating bond energy gaps with transition pressures

Solid	a (nm)	E_R (eV)	E_R/a^3 (eV nm ⁻³)	Transition pressure (kbar)	Indentation hardness (kbar)
Ge	0.566	4.3	24	120 (100)	80
Si	0.543	4.8	30	190 (155)	120
C	0.356	13.5	300	~1,000	1,000

The average bond energy gaps (E_g) for Ge, Si and diamond are 4.3, 4.8 and 13.5 eV respectively⁶. It is interesting to consider whether they are related to the transition pressures. Clearly, on dimensional grounds, it is not possible to correlate energies with pressures; one needs energy divided by volume. For simplicity we use the cube of the lattice spacing a . The results are given in Table 1.

In view of the calibration uncertainties in high pressure experiments, the agreement seems reasonable. The figures indeed suggest that the transition pressure and true indentation hardness of diamond should be somewhat greater than 1,000 kbar. It would be interesting to know how far such correlations apply to other types of solids which show a semiconductor-metallic transition under pressure. It may turn out that in some systems the bond strength is a more relevant parameter than the average bond energy gap.

We thank Sir Nevill Mott, Dr E. A. Davis and Dr A. D. Yoffe for helpful discussions and Dr C. A. Brookes for additional data on microhardness. We are indebted to the referee for bringing to our attention the paper by Vereshchagin *et al.*⁷.

Evidence of photochemical haze in the atmosphere of Greater London

PHOTOCHEMICAL pollution in Greater London, as evidenced by unnaturally high ozone concentrations, has been reported on several occasions¹⁻⁵. In Los Angeles, where photochemical activity has been experienced for many years, an obvious feature of this pollution is aerosol formation, which has been attributed to the participation of SO_2 in the photochemical reaction sequence, with subsequent formation of sub- μm sulphate particles⁶. Although SO_2 concentrations are higher in Greater London, there have been no reported measurements of photochemical haze, but Cox and Penkett⁷, by extrapolation of laboratory measurements of air samples from Harwell, have suggested that a conversion rate of $10\% \text{ h}^{-1}$ for SO_2 to sulphate aerosol may be possible in Greater London; this would be sufficient to produce large quantities of sulphate aerosol. Identification of such processes is important because evidence suggests that photochemically produced sulphate aerosols can, in certain circumstances, account for a large proportion of total particulate mass in the $0.1\text{--}1.0 \mu\text{m}$ size range⁸. This size range is important in determining the optical scattering coefficient of polluted air⁹, and hence visibility, and potentially as a respiratory tract irritant because of its ability to penetrate deeply, in combination with its chemical nature¹⁰. We report here preliminary observations based on nephelometric measurements of the optical scattering coefficient of air over central London during June to August 1976, and evidence of haze formation in the London area as deduced from the Daily Weather Reports (DWR) of the Meteorological Office (MO), and show how these relate to the occurrence of photochemical processes over Greater London.

Throughout the summer of 1976, the optical scattering coefficient, b_{scat} , and concentrations of various gaseous pollutants, including ozone, were measured at the Greater London Council's (GLC) County Hall roof-top site in central London. b_{scat} was measured by a broad-band integrating nephelometer with a quoted effective wavelength of 500 nm, and in which incoming air was heated to $\sim 20^\circ\text{C}$. Ozone was monitored by chemiluminescent reaction with ethylene. The optical scattering coefficients can be related, at least approximately, to meteorological range (visibility), L_v , by Koschmieder visibility theory¹¹, such that $L_v \approx 3.9 b_{\text{scat}}^{-1}$, where scattering, as opposed to absorption, is the dominant factor in atmospheric extinction. Figure 1 shows the 24 h mean value of b_{scat} plotted against the maximum 1-h mean ozone concentration for each 24 h period, noon-to-noon, during the 3 months, June, July and August. Expressing b_{scat} as a linear function of the ozone concentration by the least-squares method yields a correlation coefficient of 0.7, suggesting that a large fraction of the variance of b_{scat} could be associated with photochemical pollution. Further understanding of the relationship of higher values of b_{scat} to photochemical events, as evidenced by unnatural ozone concentrations, requires detailed examination of individual episodes.

Fig. 1 24-h mean values of the optical scattering coefficient, b_{scat} , plotted versus 1-h maximum ozone concentrations as recorded at the GLC County Hall site in central London for each 24-h period starting at 1200 h GMT during May to August 1976. Ozone concentrations are reported as parts per hundred million (v/v). Line through data points is the least-squares fit, with intercept 0.6 ± 0.4 , and slope 0.21 ± 0.06 , where errors correspond to 2σ . $r = 0.69$ with 82 data points.

Of particular interest is the 0600 h record of the 4-times daily DWR for 28 June. At this time a dense haze is reported from each of three MO stations at Heathrow, Kew and Gatwick, with respective visibilities of 1.8, 1.3 and 1.5 km^{12} , as measured by Gold extinction meters. The haze was denser at these sites, which lie respectively 21 km west-southwest, 13 km west southwest and 40 km south of central London, than at the seven other MO reporting stations elsewhere in south-east England, and represented the densest haze reported from any of the MO observation stations listed for Britain in the DWR during the entire June to August period¹².

Ozone, b_{scat} , and some relevant meteorological parameters are shown for this period, for central London, in Fig. 2. The ozone concentrations, which reached record reported levels for a UK city on 26 and 27 June, follow the usual diurnal pattern, while aerosol formation and growth, as measured by b_{scat} , shows an apparent time lag of some hours behind peak ozone concentrations. Time differences of this nature have also been observed in smog chamber simulations¹³, and during ambient

Fig. 2 Values of the optical scattering coefficient and ozone concentrations as recorded at the GLC County Hall site from 26 to 29 June 1976, together with meteorological data from the London Weather Centre. *a*, Solid line is b_{scat} ; dashed line is ozone; *b*, solid line is wind speed; dotted line is relative humidity.

air measurements of ozone and photochemical aerosol formation in studies carried out in the USA¹⁴. Bearing in mind the light east southeast surface wind, of speed $\sim 2 \text{ m s}^{-1}$, during the night of 27–28 June, and the calm conditions aloft (Balthum data from MO station, Cardington, Bedfordshire), it is not unreasonable to assume that the dense haze reported at the MO Heathrow and Kew sites is of the same origin as the b_{scat} peak detected at County Hall. Because ozone concentrations were higher in central London on 27 June than values reported from elsewhere in south-east England⁴, and because meteorological conditions were suitable for the generation and detection of locally produced ozone over central London on that day, we have proposed elsewhere that a substantial portion of the ozone detected at County Hall at this time may be formed from locally emitted precursors⁵. Similarly, the detection of the unusually dense haze at the downwind MO stations closest to Greater London a few hours after the unprecedented ozone concentrations is suggestive of a photochemical formation mechanism which is, in part, attributable to precursors emitted in or close to the Greater London area. During the remainder of the episode illustrated in Fig. 2, solar radiation was still high, and thus conducive to further photochemical activity. However, it is considered that the brisker, although still easterly, winds would have swept precursors into downwind areas before significant quantities of ozone or aerosol had been formed.

Table 1 records other instances during the study period, when visibility at Heathrow or Kew, as reported by the MO¹², was restricted by haze to $< 5 \text{ km}$, and was also less than at the other

MO stations in south-east England, days on which mist or fog occurred at some locations having been eliminated. Visibility degradation at Heathrow and Kew, as enumerated in the DWR, was generally highest at the 0600 h, or occasionally at the 0000 h GMT reporting times. With the possible exception of 5 June, all 24-h periods listed in Table 1 experienced light winds from the eastern sector which could have advected aerosols from the Greater London conurbation to these locations. In addition, maximum 1-h mean ozone concentrations exceeded 8 p.p.h.m. at County Hall, or elsewhere in Greater London⁵, on 80% of these occasions. Ozone concentrations of this magnitude usually indicate a significant amount of photochemical activity.

Preliminary examination of other 24-h periods which did not have significantly more haze at Heathrow or Kew than elsewhere in south-east England, but during which ozone concentrations exceeded 8 p.p.h.m. in Greater London, shows that some coincide with periods of westerly winds, while others may be associated with higher wind speeds or lower relative humidities. It is also evident that, on some occasions, high ozone concentrations in the London area are not due to local photochemical activity, but to transportation from remote sources^{5,15}.

We thank Dr M. J. R. Schwar for discussion, and R. T. Kelly, Scientific Adviser to the GLC, for permission to publish this work. The views expressed do not necessarily represent those of this Council.

Volcanic dust and changes in Northern Hemisphere temperature

RADIATION calculations which seemed to demonstrate that changes in the temperature of the Northern Hemisphere on a wide variety of time scales could be attributed to changes in the amount of volcanic dust in the atmosphere have been reported by Pollack *et al.*¹ In particular, they claimed that the observed average temperature depression of 0.3 °C two years after major volcanic eruptions agreed with their calculated value and that the clearance of volcanic dust after the frequent strong eruptions at the end of the nineteenth century was responsible for a rise in the Northern Hemisphere temperature of 0.5 °C between the decades starting 1880 and 1935. Here we look critically at these two claims in the light of the known noisiness of meteorological data and the uncertainties in the estimates of volcanic dust in the atmosphere.

For the observed changes following major eruptions Pollack *et al.*¹ used values given by Bray². These were for the years following all volcanic eruptions since 1750 for which Lamb³ had estimated the total dust veil as 1,000 units or more. Lamb⁴, however, gave revised estimates of the dust veil index (DVI), and a selection of years on the same criterion (DVI ≥ 1,000) results in three changes from Bray's list. The original and altered dates (in brackets) are: 1752, 1766, 1775, 1783, 1803 (1805), 1807 (1809), 1815, 1831, 1835, 1846, 1878 (1875), 1883, 1902.

Average temperature anomalies in the years following the two selections are shown in Table 1. The temperature anomalies for the individual years were obtained from data by Arakawa⁵. They are estimates for the Northern Hemisphere begun by Koeppen and continued by Humphreys up to 1921. After 1811 the basis of the temperature series was improved by the inclusion of some tropical locations. Thus the temperature anomalies for the major eruptions after 1811 in Bray's selection have been worked out and are given in Table 1. Bray based his claim that the temperatures for years +1 and +2 were reduced by volcanic eruptions on the fact that the number of positive departures in those years was well below that to be expected by chance (about 1 in 100 for year +1 and 9 in 100 for year +2). In the revised selection there is still a small probability of the result being due to chance for year +1 but for year +2 the probability of a chance result is as high as 1 in 5. As far as the value for year +2 is concerned, the reality of the result apparently depends on the selection of years.

It may be desirable to examine the reality of the results using the magnitude as well as the sign of the anomalies. To test the significance of the residuals in Table 1 we need to estimate the standard error of samples of this size. The standard deviation of the yearly anomalies of the Koeppen-Humphreys series from 1750 to 1920 with the exclusion of the five years following each of the 13 major eruptions is 0.50 °C. Thus averages of 13 values chosen at random from this series can be expected to have a standard deviation from zero of 0.14 °C. It is therefore very likely that the value of -0.27° for year +2 to which Pollack *et al.*¹ refer contains a substantial sampling error. The values of

Fig. 1 Calculated temperatures for two sets of DVI. *a*, All eruptions mentioned by Lamb; *b*, well substantiated eruptions ref. 4 Table 7a.

-0.13 and -0.06 in Table 1 could just as well be taken as the effect of volcanic dust.

The first part of their claim seems to rest, therefore, on rather shaky ground—the observed temperature depression for year +2 is apparently nearer -0.15 ± 0.14 °C. If we suppose that there is some depression of temperature following major eruptions but that it is well below 0.5 °C, then for the second part of their claim to be valid there must have been a concentration of strong eruptions and enough persistence of the temperature depression following each to bring the hemispheric temperature 0.5 °C below the clear atmosphere equilibrium level for several years. We now use a simple mathematical model to see if this could have been the case.

The solar radiation reaching the earth's surface is given as S in the original state and $S(1-\alpha)$ when volcanic dust is present in the upper atmosphere, with corresponding equilibrium temperatures T_0 and T_0^1 . Following Budyko⁶, we assume the net outgoing longwave radiation from the surface to be a linear function of T when global averages are being considered, so that $S = aT_0 + b$ and

$S(1-\alpha) = aT_0^1 + b$, and $\Delta T_E = T_0 - T_0^1 = S\alpha/a$. The change between the two equilibrium temperatures is described by

$$\frac{CdT}{dt} = S(1-\alpha) - aT - b, \quad T = T_0 \text{ when } t = 0$$

where C is the equivalent heat capacity of the global surface layer. This leads to

$$\Delta T = \Delta T_E (1 - \exp(-kt)) \quad (1)$$

where $\Delta T = T_0 - T$ and $k = a/c$. Taking the data from Table 1 of Pollack *et al.*¹ it is apparent that, to a first approximation, ΔT_E for their calculation can be written $[8(\Delta\tau)]$ °C where $\Delta\tau$ is the change in optical depth due to the volcanic dust. For an average cloudiness of 50%, Budyko⁶ gives $a = 0.09$ kcal cm⁻² month⁻¹ °C⁻¹. The appropriate value of C is difficult to define precisely, but a change over a few decades is likely to be determined primarily by the depth of the ocean whose temperature is significantly affected by the temperature change. Assuming, as Schneider and Mass⁷ did, that this depth is about 75 m, and taking into account the fact that the oceans cover 71% of the earth's surface, an appropriate value for C is 5.3 kcal cm⁻² °C⁻¹. This gives a relaxation time for the surface temperature of C/a which is nearly 60 months, and of the same order as that apparently used by Pollack *et al.* and Oliver⁸ in a similar treatment of the effects of volcanic dust.

Table 1 Temperature anomalies (°C) after major eruptions

Equation (1) can be recast in the form

$$\delta(\Delta T) = k[\Delta T - \Delta T_E]\delta t \quad (2)$$

$\delta(\Delta T)$ is the change in temperature during a time interval δt where the temperature depression is ΔT and the equilibrium depression is ΔT_E . Pollack *et al.*¹ have assumed that eruptions of the magnitude of Krakatoa produce a change in optical depth of 0.1, and Lamb⁴ supposes that the DVI for the first year after such an eruption is 400 units. Accordingly we suppose ΔT_E for each year is given by $0.8 \times \text{DVI}/400$ and equation (2) using time steps of one year becomes

$$\delta(\Delta T) = 0.2 [\Delta T - (0.8 \times \text{DVI}/400)] \quad (3)$$

There was a sequence of strong volcanic eruptions during 1878-93 and two sets of total annual DVI values for this period taken from Lamb⁴ are given in Table 2.

The calculated temperature anomalies from equation (3) for the period 1878-1920 for two such sets of data extended to 1920 are shown in Fig. 1. Five-year mean temperature anomalies for the two sets are given in Table 3, together with values from the Koeppen-Humphreys and the Mitchell-Budyko series of Northern Hemisphere temperatures. The latter are expressed as anomalies from the mean for 1870-1921, which makes them comparable with the former series.

The calculations indicate that the maximum depression of temperature due to volcanic dust may be expected in the decade 1885-94 and that with the assumed relaxation time, temperature would be back to the clear atmosphere value by 1920. The calculated and observed changes of temperature over this interval are shown in Table 4.

The value for all eruptions seems to be too large: that for the well-substantiated eruptions is reasonable when compared with the Mitchell-Budyko series, the ones usually accepted in climatic change studies. It is generally agreed that there was very little, if any, volcanic dust in the atmosphere after 1920 until the late 1940s at the earliest. Humphreys⁹ remarks that by July 1914, to judge from the pyrohelioelectric data, the dust from the Katmai (Alaska) eruption in 1912 had fully passed and the measurements remained steady to 1940. Thus it is improbable that any of the

warming after 1920 can be attributed to the volcanic effect. From Table 4 this puts a likely upper limit of 0.2 °C on the contribution of volcanic dust to the climatic warming between the end of the nineteenth century and the 1940s.

Volcanic dust influence on glacier mass balance at high latitudes

EXPLOSIVE eruptions, which inject large quantities of volcanic dust into the earth's upper atmosphere, are believed to be important factors in climatic change. Theoretical considerations suggest that the greatest climatic effect of a stratospheric dust veil would be at high latitudes during summer months, when solar radiation passes through the greatest depth of atmosphere and the surface is illuminated continuously¹. Furthermore, the residence time of volcanic dust is greatest at high latitudes, where it may remain in the upper atmosphere for a decade or more, depending on particle size and initial injection height². Here we present evidence that the eruption of Mount Agung (8 °S, 115 °E) in March 1963, was responsible for a marked change in the climate of the North American High Arctic and that this change has had a significant impact on glacier mass balance in the region.

The North American High Arctic (north of lat 74 °N) contains the greatest concentration of land-based snow and ice outside Greenland and Antarctica, with glaciation levels in some areas <300 m above sea level³. The ablation, or melt, season averages 86-123 d yr⁻¹ near sea level and up to 53% of annual precipitation may occur during this period⁴. At higher elevations, the ablation season is even shorter and all summer precipitation falls as snow, increasing surface albedo and continuously retarding the melt process at the glacier or ice cap surface. Because this season is so brief, a change in

Fig. 1 Annual $(T_x - T_n)$ MDD totals at Thule, northwestern Greenland, showing the abrupt decrease in overall 'summer warmth' after the eruption of Mount Agung in 1963.

summer climate has significant impact on glacier mass balance in the region.

An abrupt and significant change in the summer climate of the Canadian Arctic occurred between the summer of 1963 and 1964 and the resulting conditions have persisted^{4,5}. Mean July freezing-level heights in the atmosphere in the decade after 1963 were up to 500 m lower than in the preceding decade. At the surface, mean maximum July temperatures since 1963 have averaged 1.1 °C to 2.7 °C lower than in the pre-1963 period. This fall in temperature was partly brought about by a change in the frequency of extremely warm summer days. At Alert, for example, there was an average of 2.3 d yr⁻¹ with maxima >15.5 °C (60 °F) between 1950 and 1963; between 1964 and 1976 there have only been four such days⁴.

Particularly useful indices of the change in total summer 'warmth' are annual melting degree day totals over the past 25–30 yr. A melting degree day (MDD) is the difference between 0 °C and daily maximum (T_x MDD) or minimum (T_n MDD) temperatures, when the latter are above 0 °C. Melting degree day totals have fallen significantly throughout the High Arctic since 1963 (Table 1). This is most apparent at Thule, Greenland (Fig. 1), where mean MDD totals 1964–1974 were only 65% of the average from 1947 to 1963, with the greatest changes occurring in the months of June and July.

Table 1 Change in average annual melting degree day totals

Station	(T_x, T_n, C)		Mean: 1964–76	%*
	First complete annual record	Mean: start of record to 1963		
Thule	1947	937	604†	65
Eureka	1948	808	702	87
Resolute	1948	616	462	75
Alert	1951	505	440	87
Isachsen	1948	458	339	47

*Post-1963 average as a % of pre-1964 average.

†1964–74 inclusive.

How has this change in summer climate affected glacier mass balance in the region? It has been argued that mass balance measurements from the north-west sector of the Devon Ice Cap (taken since 1960 and comprising the longest series of such measurements in the Canadian Arctic) show no evidence of a cooling trend⁶. These data are highly correlated with T_n MDD indices at Resolute and Thule ($r = 0.94$, $y = 2.79x - 224.8$; $P < 0.001$) (Thule and Resolute are the two long-term weather stations closest to the Devon Ice Cap, ~400 km and ~350 km to its east and west, respectively. It is interesting that extrapolation of the relationship to a situation where the annual T_n MDD total is zero results in a mass

balance of 225 kg m⁻² a⁻¹, which is very close to present accumulation amounts on the summit of the ice cap (220 kg m⁻² a⁻¹) (ref. 6.) Using this regression equation, mass balance on the north-west Devon Ice Cap can be reconstructed back to 1947–48, when instrumental observations were first kept at both Thule and Resolute (Fig. 2). By putting the recent mass balance measurements in perspective, the post-1963 change is seen to be highly significant. Between 1947 and 1963, the ice cap continuously lost mass, with greatest losses occurring in the later 1950s. In the last decade, positive balance years have outnumbered negative balance years, although overall there has still been a net mass loss since 1963. This is seen clearly in Fig. 3, where cumulative mass losses since 1947 are shown. Between 1947–48 and 1933–64, we estimate the Devon Ice Cap lost ~3,500 kg m⁻², whereas since 1963–64 the net loss has been <350 kg m⁻². Similar studies using the only other long series of mass balance data in the High Arctic (from the White Glacier, Axel Heiberg Island)^{7,8} show that these results are probably typical of an extensive area of the North American High Arctic and that the change in climate since 1963 has thus had an impact on snow and ice bodies of the region.

Fig. 2 Reconstruction of mass balance on the northwestern sector of the Devon Ice Cap, based on a regression equation between Devon mass balance since 1960 and average T_n MDD totals at Thule and Resolute. Stars indicate actual mass balance observations from Koerner⁶, 1977.

It is suggested that this change in summer climate is related to the massive input of volcanic dust into the upper atmosphere as a result of the eruption of Mount Agung in March 1963. The total dust veil in the Northern Hemisphere from 1963 to 1968 was the greatest since the period 1883–90, following the huge eruption of Krakatau (6 S, 105 E) in August 1883 (refs 1, 2). Dust veil index values in the mid-1960s were 1,100 compared to 1,500 after Krakatau². Recent work^{10,11} indicates that the greatest change in Northern Hemisphere surface temperatures in the past 25 years was related to the input of Mount Agung dust into the stratosphere. The dust affected solar radiation receipts at high latitudes of the USSR (71–81 °N) by late 1963 (ref. 14), and the effect is clearly seen in solar radiation and temperature data for Resolute (Fig. 4). In summer 1964, diffuse radiation reached the highest levels ever recorded and direct radiation fell to the lowest values on

record. This increase in diffuse and decrease in direct radiation (often with no change in total radiation receipts) is a typical 'volcanic dust signal' and is very similar to that recorded at Aspendale, Australia in summer 1963, when direct radiation was reduced by 24% (by Agung dust in the stratosphere) but diffuse radiation almost doubled¹³. Unfortunately no solar radiation data are available for Resolute before 1961, so it is impossible to compare post-Agung values with any long-term pre-eruption value. However, there is some indication in Fig. 4 that summer diffuse radiation values decreased slowly from 1964 to 1969 (while direct radiation values increased). This may reflect stratospheric dust gradually settling out following the eruption. It is interesting that summer solar radiation receipts in 1972 were similar to 1964; diffuse radiation receipts were very high, and direct radiation very low. The summer of 1972 was the coldest since records began in 1947 (the only summer colder than 1964).

Figure 4 also shows an inverse relationship between summer diffuse radiation and $(T_x + T_n)$ MDD totals at Resolute. The correlation ($r = -0.83$) is statistically significant ($P < 0.01$), and indicates that diffuse radiation totals are closely linked to summer 'warmth', which in turn is a critical factor affecting glacier mass balance, as discussed above. Hence, in periods with large amounts of volcanic dust in the atmosphere, diffuse radiation totals would be high, surface MDD totals would be low and glacier mass balance would be positive.

If the Agung eruption was responsible for the change in ablation season conditions and mass balance during the 1960s, then it is likely that other periods of frequent volcanic activity resulted in temperature changes in the High Arctic at least as large as those observed since 1963. Thus it is probable that in the period 1750–1880 (when there were at least 14 eruptions of a magnitude equal to or greater than that of

Fig. 3 Reconstruction of cumulative mass loss on the north-west Devon Ice Cap since 1947. The abrupt change in net loss since 1963 is clearly shown.

Agung) ablation season temperatures in the High Arctic were extremely low. Consequently, glacier mass balance was almost certainly positive during this interval, as indicated by stratigraphic studies of the Devon Ice Cap⁸ and the Gilman glacier¹⁴. Conversely, the period 1920–63 (when volcanic activity was exceptionally low) was probably characterised by predominantly warm summers with more negative mass balance conditions¹⁵. Hence, the warmer period seen in Fig. 1 before 1964 was probably typical of summers back to the 1920s and

Fig. 4 Mean diffuse solar radiation receipts (June–August) at Resolute, NWT. The marked increase in diffuse radiation following the Agung eruption and the inverse relationship between diffuse radiation and $(T_x + T_n)$ MDD at Resolute ($r = -0.83$) is shown. Solid line, June–August, diffuse radiation; dashed line $(T_x + T_n)$ MDD.

the climate and mass balance conditions of the post-Agung period may be more typical of conditions characteristic of the last century.

Low sea levels, droughts and mammalian extinctions

DRASTIC environmental changes and mammalian extinctions have been reported to coincide with low ocean levels. These low levels were, therefore, interpreted as being caused by major climatic coolings with glacial eustatic regressions, although no continental glaciations, or cooling of Pleistocene-type, has been recorded outside Antarctica earlier than ~ 3 Myr ago. We give here a simple geophysical solution to this problem, which is that any regression (glacial eustatic, tectono eustatic or geoidal eustatic) will also affect the ground water table under the continents by geoid changes and hence lead to drastic environmental and faunal changes, including extinctions. Instead of extinction by temperature decrease, the chain reaction 'regression-drought-extinction' is proposed. Continental geoid fluctuations affecting the ground water table are not only essential for correct interpretation of the pre-Pleistocene climate but also for understanding and modelling of the Pleistocene climate, because the dryness in equatorial and low-latitude regions during ice ages may be interpreted rather as an effect of the lowered geoid

and ground water table than of the temperature decrease, although, in this case, the latter is of a significant order of magnitude.

In documenting periods of drastic environmental changes and mammalian extinctions, two major periods of changes can be recognised¹: one beginning with the Eocene–Oligocene boundary at ~ 37 Myr and one in the late Miocene (Messinian) at ~ 5–6 Myr. Both these periods were found to correspond to major sea-level regressions¹. These changes, however, seem to have been caused by different mechanisms from the Pleistocene ones, which caused major global climatic changes of fairly short duration one of the best examples of the latter being the 10,000 BP change in global climate (the Pleistocene–Holocene boundary), by Behrensmayer¹, now also shown to correspond to a faunal change and a sudden appearance of a microlithic culture in East Africa.

Absolute, 'eustatic', sea-level changes can be brought about in three different ways^{1,2,10}: (1) glacial-eustasy; climatic changes controlling the glacial volume changes and hence the ocean water volume; (2) tectono-eustasy; earth movements (such as orogeny, tectonism, plate tectonics and isostasy) controlling the world ocean basin volume; (3) geoidal-eustasy; gravitational and rotational changes controlling the geoid configuration and ellipsoid.

The first two vertical eustatic type of changes may be regarded as 0-harmonic changes of the geoid (vertical) and the third one as changes in any of the other harmonics (the configuration). None of these changes can occur without corresponding rotational and gravitational changes. A eustatic change in the oceans will, of course, also change the geoid under the continents and by this affect the crustal movements, the ground water table, and so on. This obvious effect of a eustatic regression on the ground water table has not been discussed before, although it seems to be a solution to major Cenozoic changes in local environment and fauna (without having to infer drastic global climatic changes of Pleistocene type) as well as for the dryness in equatorial and low-latitude regions during ice ages³.

Ingle¹ showed that the Oligocene began with a major cooling, sea-level drop and decrease in diversity in several faunal elements. Van Couvering¹ showed that the Eocene–Oligocene transition corresponds to changes from general forests to woodlands both in North America and in Central Asia. Bakker¹ has demonstrated that the Eocene–Oligocene boundary corresponds to a major evolutionary discontinuity during which the top predator sub-guilds were emptied by extinction due to some environmental change initiated by a world-wide regression.

What could have caused the sea-level drop and the corresponding climatic and faunal changes? There are no records of any major glacial increase in Antarctica at this time¹², and if there had been, an Antarctic ice cap increase is not likely to be linked to global climatic changes of the type we know from the Pleistocene.

The regression recorded must have been caused by orogeny and/or plate tectonics increasing the ocean basin volume leading to a tectono-eustatic drop in sea level, with a corresponding lowering of the geoid under the continents. A lowering of the geoid under a continent means lowered ground water table and hence drought and other local environmental changes. This is exactly what van Couvering¹ reported from the Eocene–Oligocene boundary. These environmental changes, in its turn, explain the drastic faunal changes reported by Bakker¹ and Ingle¹. The change in vegetation affects the albedo and may, therefore, lead to some general change in climate. Such an effect may, together with minor glaciers in Antarctica, explain the temperature drop recorded in some ¹⁸O curves from the South Pacific⁴.

The expansion of the Antarctic Ice Cap to the Queen Maud Glaciation⁵, the cooling in the South Pacific^{6,7} and the regression in New Zealand⁸ have been correlated with the regression in the Mediterranean during the Messinian⁹. Although this correlation may be questioned¹⁰ and need further confirmation, there can be little doubt that the Miocene ended with a worldwide glacial-eustatic regression. Ryan¹ presented solid geological–geophysical data on the distinct regression and erosion in the Mediterranean

in relation to the formation of the huge salt layers of the Messinian¹¹. Van Couvering¹ showed that the land vegetation underwent a major change at about 5 Myr (during the Messinian): in North America and in Central Asia, this marks the sudden beginning of prairie formation. Webb¹ showed that the North American vertebrate fauna records a mass extinction somewhere between 7 and 5 Myr without any corresponding increase in number of immigrants, indicating an environmental origin of this extinction. From Florida, he reported a simultaneous regression of at least 40–50 m (followed by a transgression of at least 50 m).

The model suggested for this late Miocene (Messinian) regression–drought–extinction is a very similar pattern to that of the Eocene–Oligocene event, except that this time the regression is caused by glacial-eustasy. No extensive worldwide cooling as in the Pleistocene is suggested, only a chain reaction on the regression: the lowering of the geoid causing a general ground water fall giving rise to drought and vegetational changes that affected the fauna so much that mass extinction is recorded.

The present models offer a simple and logical explanation for the established correlation between regressions, vegetational changes and extinctions during the Cenozoic without having to imply drastic and worldwide changes in climate like those characterising the later part of the Pleistocene (the 'glacial Pleistocene'). The new factor that makes the chain logical is simply the lowering of the geoid under the continents and its effect on the ground water and the drought.

Fluvially transported charcoal gives erroneous ¹⁴C ages for recent deposits

IN carbon dating of material included in fluvial deposits, it is usually assumed that either there is little age difference between the dateable material and the fluvial deposit, or that the ¹⁴C sample and the deposit in which it is contained are sufficiently old for the age difference to be of little consequence. We report here on how a series of dates on charcoal from the bed of the Macdonald River, New South Wales, Australia, casts doubt on these assumptions and indicates that serious errors can occur in relating the radiocarbon ages of charcoal samples to the fluvial deposits in which they lie.

The Macdonald River drains a catchment area of about 2,000 km², composed almost entirely of flat-lying Triassic sandstones and shales¹. The river flows into Broken Bay (33°55'S, 151°15'E), a large ria drowned during the last rise of sea level². The lower reaches of the Macdonald are tidal, and the valley floor is extensively alluviated. Deposits consist almost entirely of quartz sand with abundant charcoal. Over 95% of the catchment remains forested, mostly by dry sclerophyll woodland, dominated by *Eucalyptus* spp. Bushfires are not uncommon, and were probably an important environmental occurrence long before the arrival of European man less than 200 yr ago³.

Fig. 1 Radiocarbon age against charcoal particle size.

Sandstone hillslopes in the Macdonald catchment, whence most charcoal fragments must ultimately be derived, provide ample sites where charcoal could be stored. Open joints more than 0.5 m wide and over 1 m deep are filled with loose quartz sand and tree debris; slopewash seems important in sediment transport and fallen sandstone blocks and trees accumulate sediment on their upslope sides; small alluvial/colluvial fans and chutes also store sediment on the slopes which rise as much as 200 m above the river. Although age estimates on the largest trees in the catchment are not available, there seems no reason to doubt that individuals of some *Angophora* and *Eucalyptus* spp. live to ages beyond 200 or 300 yr. Thus some charcoal fragments could have radiocarbon ages of several hundred years before they reach the valley floor.

Sediment storage, transport and redeposition are also characteristic of the alluviated valley floor¹. Channel beds and banks are composed almost entirely of loose sand; bank undercutting and channel migration are common. Even at low flow, discharges of $1 \text{ m}^3 \text{ s}^{-1}$ or less can transport much of the bed load including charcoal fragments. During flood stages extensive alluviation of the floodplain occurs and tabular bars and benches are built on the bed and along the banks. Charcoal is a substantial component of all these fluvial deposits; beds of almost pure charcoal fragments, more than 10 cm thick, and up to several square metres in extent, are quite common in the Macdonald Valley and similar catchments. Given these catchment conditions, there is every expectation that the ages of sediment deposition and the contained charcoal should be at variance.

At a site just upstream of the present tidal limit charcoal fragments were collected from the mobile bed of the present stream during low flow from channel bars only 2–3 cm above water level. The collected charcoal was either in transit or had been mobile in the previous few days. The bulk sample of several thousand grams of wet charcoal was dried and gently sieved into the following size fractions: 0.5–1.0 mm (SUA-620), 1.0–2.0 mm (SUA-619), 2.0–4.0 mm (SUA-618) and > 4.0 mm (SUA-617).

Samples were boiled for 10 min in dilute phosphoric acid, washed with distilled water, soaked overnight at room temperature in an alkaline phosphate solution, washed and boiled again in dilute acid. This pretreatment procedure has been shown to remove acid and alkali soluble contaminants with minimal destruction of the charcoal⁵. Pretreated samples were converted to benzene by standard techniques and counted for an average of 1,200 min each using the liquid scintillation technique⁶.

The radiocarbon ages increase with decreasing charcoal fragment size (Fig. 1), probably as a result of breakdown of the charcoal pieces with time during intermittent transport and storage. Because surface area, and hence the potential for organic contamination, increases with decreasing particle size, the observed trend is the opposite to that expected if contamination were present⁶.

As the sediment with which the Macdonald River charcoal was associated is modern (AD 1976), the relationship between the age of the deposition of the sediment and the age of the charcoal is not simple, but depends on the relative mix of particle sizes in the charcoal sample selected for assay. For example, a sample collected earlier from the same site and assayed without knowledge of its particle size distribution (other than that all fragments were finer than about 8 mm) produced an age estimate of 560 ± 90 yr b.p. (SUA-313).

A similar sample, collected from the present stream bed, but some 26 km upstream from the tidal limit, gave an age estimate of 440 ± 95 (SUA-512/1). A second analysis on a sample from the same plastic bag gave an age estimate of 80 ± 95 (SUA-512/2). The pooled mean of these two results is 260 ± 70 yr b.p. Polach's Z statistic⁷ indicates that the ages of SUA-313 and SUA-512 are significantly different at about the 0.2% level, thus supporting a hypothesis that charcoal fragments associated with present-day fluvial deposits increase in age with distance downvalley. Reasonable as this hypothesis is in the light of current knowledge of floodplain storage of sediment and channel migration⁸, the data presented in Fig. 1 and the lack of charcoal particle size control on SUA-313 and SUA-512 indicate that it cannot yet be substantiated.

In the light of these results, dates on older sediments in the Macdonald River area also present problems of interpretation. A sample of charcoal from a slightly indurated reddish clayey sand exposed in the stream bed near the tidal limit (but believed to be a colluvial deposit) provides an age estimate of $3,350 \pm 110$ yr b.p. (SUA-314). Most of the charcoal pieces in this sample were probably finer than 2 mm.

At a site 10 km upstream, charcoal (finer than about 8 mm) was collected 4.65 m below the surface of a terrace which stands about 7.6 m above the stream bed. This sample was dated at $1,830 \pm 100$ yr b.p. (SUA-315).

Although at the time of sample collection and radiocarbon assay these age determinations were believed to provide reasonably accurate age estimates on the geomorphic surfaces, Fig. 1 indicates that no great significance can be attached to them. We can only assume that the reported ages are maximum ages for the deposits in which the charcoal fragments are enclosed and note that the reported dates and the true ages of the sediments might differ by 1,500 or more years.

There is no reason to believe that the results of assays reported here are unique. Other valleys along the eastern part of New South Wales are very similar in lithology, topography and climate⁹, and we can ask whether similar relationships between charcoal particle size and age do not also apply. Thus, age dates for alluvial fills in the adjacent Wollombi and Colo catchments reported by Hickin and Page⁹ must be regarded as maximum ages, even though these authors showed that the fills were much younger than had previously been supposed. Ages reported by Young¹⁰ and Warner¹¹ for Holocene terrace and floodplain systems along the New South Wales coast must also be treated as maxima that may be seriously in error. We might also surmise that age estimates on estuarine and coastal deposits overestimate the antiquity of landforms where charcoal ulti-

mately derived from terrestrial catchments has been assayed.

It seems unlikely that the longevity of charcoal in fluvial transport systems is peculiar to the eastern New South Wales environment. The results reported here may cast doubt on late Holocene chronologies established in various parts of the world (see ref. 12), and may help to explain the overlapping ages of alluvial fills apparently separated by well-developed soils, or to account for marked differences in age estimates of the one stratigraphic layer where some samples are from hearths, for example, and others are derived from transported charcoal.

Zinc in north-east Pacific water

ALMOST all lead data for the marine environment are inaccurate, contends Patterson¹, because of gross contamination from faulty sampling and analytical procedures. Most marine chemists assume that similar problems are associated with other trace elements as well. Hence, clean sampling and analytical techniques have been adopted. These procedures, in conjunction with the improvement of analytical instrumentation, have resulted in reports on Cu, Ni and Cd (refs 2–4; 3, 5; and 3, 6–8 respectively) levels in seawater that are at least an order of magnitude lower than those previously thought to exist. We report here that Zn concentrations (10–600 ng l⁻¹) are also considerably lower than previously published estimates of 1–30 µg l⁻¹ and that its vertical distribution (surface depletion, deep enrichment) is very similar to that of a major plant nutrient; that is, silicate.

Because Zn is ubiquitous, chances for contamination are at least as great as those for Pb and hence, accurate Zn data can only be obtained using strict precautions. Nevertheless, even with the application of ultra-clean methods, the reliability of Zn data must also be demonstrated by employing at least two independent techniques. Thus, we have been using two different preconcentration procedures (organic extraction and chelex resin exchange) on unfiltered water samples collected with two sampling systems: a modified Go-Flow bottle suspended on Kevlar[®] line and a sophisticated protected-deep-ocean-stable-lead sampler designed and constructed by Schaule and Patterson of the California Institute of Technology. Analyses were performed by flameless atomic absorption spectrophotometry.

Fig. 1 Depth profiles of Zn and Si (■) off the central California coast (see Table 2). The Zn profile line was drawn using average organic extraction data (●). Chelex values are indicated by (○).

Further details on sampling and analytical methods have been published elsewhere^{7,8}.

The two systems were first compared in December 1976 at a station 100 km west of the central California coast (Table 1). Surface water was collected by holding carefully cleaned bottles below the water surface whilst rowing a raft into clean water. Zinc levels from these samples were then compared with those obtained near the surface using the two sampling systems mentioned above. Replicate analyses using organic extraction were 63 and 38 ng Zn l⁻¹ for the raft samples. These values agreed with those obtained at 30 m using the Go-Flow system (52, 42 ng Zn l⁻¹). Triplicates of the 30 m Go-Flow water also showed similar concentrations (46, 38, 23 ng Zn l⁻¹) when analysed after pre-concentration with chelex. Further evidence that the Go-Flow sampling system did not grossly contaminate samples for Zn was also shown when levels obtained at 920 m with the Go-Flow sampler were compared with those obtained at 1,200 m using the CIT sampler. Replicate analyses using organic extraction at the two depths were remarkably precise and were not significantly different (495, 503 against 519, 515 ng Zn l⁻¹). The 920 m samples analysed using chelex, however, were grossly contaminated. This occurred at some time after the water was withdrawn from the sampling system. (Because of space limitations, chelex pre-concentration was not performed in the filtered-air-clean lab on this cruise.) The remaining Zn values from 1,380 m (Go-Flow) and 2,300 m (CIT) were in close agreement regardless of sampler or preconcentration method. Thus, with the exception of one set of contaminated samples, we believe that the data in Table 1 represent reasonable first estimates for Zn in seawater.

In order to confirm these initial findings and to obtain a more detailed profile, we collected additional samples in the

Surface water was collected from a raft. The remaining samples were collected using Go-Flow bottles (GF) and Schaule's and Patterson's deep-water-stable-lead sampler (CIT). Zinc was pre-concentrated by organic extraction and chelex resin exchange.

*Obviously contaminated

same general area in April 1977 (Table 2). Essentially the same methods were used, however, on this cruise, all ship-board sample handling was performed in a filtered-air-clean lab and the Go-Flow system was further modified to lessen chance for contamination. Very good agreement was achieved regardless of sampler type or pre-concentration method used. The only exception was the 50 m sample (the first collected) which, we believe, was contaminated. In order to corroborate the precision of the two methods, chelex data were regressed against organic extraction data from the same depths. A correlation coefficient of 0.984 ($n = 11$) was obtained. The resulting equation ($\text{ng organic extract Zn} = 17.3 + 0.99 [\text{chelex Zn}]$) indicated that the organic extraction values were generally higher than those obtained using chelex. The apparent reason for this discrepancy is the fact that minor amounts of Zn (approximately 10 ng l^{-1}) seem to pass through chelex resin. This was observed when selected effluent samples from the chelex columns were analysed by organic extraction. In any event, in terms of both quality and quantity, we believed that the

organic extraction values more closely represented environmental concentrations and these data were used for the depth profile shown in Fig. 1.

At first glance, the depth profile for Zn is not unlike profiles for Cu, Ni and especially Cd (refs 2-4; 3, 5; and 6-8 respectively). Zinc exhibits surface depletion and deep enrichment. What is extraordinary about Zn, however, is the magnitude of the deep enrichment and surface depletion. When the deep maximum value (622 ng l^{-1}) is divided by the average surface raft level (8.5 ng l^{-1}), a ratio of 73 is obtained. In contrast, similar ratios for Cu and Ni are 2-3, while Cd has a ratio of about 30. As our surface Zn values were obtained in California Current waters with appreciable nutrients still present near the surface, it is probable that open ocean surface waters, where nutrients are completely depleted, will have still lower Zn values in the order of $1-5 \text{ ng l}^{-1}$. Hence, deep-surface ratios in the hundreds may also be anticipated.

Phosphate, nitrate and silicate analyses were also performed on many of the water samples collected for Zn. Since maximum PO_4 and NO_3 levels occurred at 800 m, it was immediately apparent that the zinc profile was more nearly similar to that observed for silicate (Fig. 1). A plot of silicate levels against zinc (Fig. 2) yielded a correlation coefficient of 0.992 ($n = 10$). The resulting equation was $\text{ng Zn l}^{-1} = -12.1 + 3.98 (\mu\text{mol Si l}^{-1})$.

This highly significant correlation ($P < 0.01$) between Si and Zn certainly was not expected. Because of zinc's biological involvement with all organisms, one would expect a stronger correlation between Zn and P and N than between it and Si. Clearly, the high correlation between Zn and Si does not necessarily mean that a direct relationship between the two elements actually exists. Nevertheless, Zn's depth profile, the apparent relationship between it and Si, Zn's marked surface depletion and the fact that phytoplankton concentrate large amounts of this element¹⁰ all suggest that diatoms play an important role in the biogeochemical cycling of this element.

We believe that the data reported here are the most accurate yet observed for Zn. Previously reported Zn values ranging from one to tens of $\mu\text{g l}^{-1}$ are undoubtedly the result of faulty sampling and analytical procedures.

We thank B. Schaule and C. C. Patterson of CIT for the aliquots of water provided from their sampler; also Rob Franks of the University of California, Santa Cruz, for

Dates, rates and angles of faulting in the Peru-Chile Trench

THE high convergence rate between the Nazca Plate and the South American continent¹ (10 cm yr^{-1}) has been reported to result in rapid rates of vertical tectonism in the trench off northern Peru^{2,3}. This paper presents additional evidence for recent, reverse faulting along the Peru-Chile Trench and new evidence for an older episode of normal faulting. We discuss the implications of this data for the timing and the angles of faulting at convergent plate boundaries.

Steep scarps with offsets of several hundred metres have been described on the outer slope of the Peru-Chile Trench^{2,4,5}. Most of these features are thought to be caused by normal faulting as a result of tensile bending stresses in the upper oceanic lithosphere as the lithosphere descends into the trench^{4,6}. Regional studies show that large fault blocks are not present west of the convergence zone, but begin forming 30-60 km seaward of the trench axis as the oceanic plate begins to bend downward⁴. Using a 10 cm yr^{-1} convergence rate and assuming that the scarps now in the axis formed 30-60 km to the west gives them an age of formation of 300,000 to 600,000 yr BP. This is a maximum age since some faults also form after the plate begins to descend into the trench⁴.

Several of the scarps within the trench axis were dredged during the FDrake cruise in 1975 (Fig. 1). The upper layer 2 basalts recovered⁷ were either freshly fractured with unaltered surfaces or in some instances had thin manganese coatings up to a few tenths of a millimetre thick. None of the basaltic material showed any measurable alteration⁷ of the type reported for basalts exposed to seawater for extended periods of time⁸. Using typical accumulation rates for manganese coatings in the deep ocean of 1 to 4 mm Myr⁻¹ (ref. 9), the thin manganese coatings represent exposure times of a few hundred thousand years or less. Although both methods of estimating the age of faulting are imprecise, they are independent and consistent with each other, suggesting that many of the fault scarps now in the axis formed since 500,000 yr BP.

Continently derived turbidites in two cores displaced high above and seaward of the trench axis have already been used to document vertical movements in the Peru-Chile Trench^{2,3}. Four additional cores have now been sampled and dated by the ¹⁴C method (Fig. 2, Table 1). The cores consist of fine to medium-grained sand turbidites which originate on the continental shelf and slope and flow down into the trench axis

Fig. 1 Dredge sites and fault scarps within the Peru-Chile Trench. Vertical elevation in a, = 9:1; b, = 23:1; c, d and e, = 5:1.

basin². To reach their present elevated positions seaward of the trench axis would require more upslope transport than is achieved by turbidity current flows in any known depositional environment (see, for example ref. 10). Faulting and vertical movement of the oceanic crust within the trench axis is the most feasible mechanism for isolating these deposits above the present level of turbidite deposition. Dating the uppermost turbidite in each core gives a maximum age of initial isolation. Dividing this age by the height above the trench axis yields a minimum rate of vertical displacement (for details see ref. 2, Fig. 10). The calculated rates of displacement for these sites range from 3 to 22 cm yr^{-1} for vertical offsets of up to 990m (Table 1). These rates of vertical tectonism are higher than any others of which we are aware and are to our knowledge the only such estimates made within a trench axis.

Based on regional bathymetry and structures, uplift of small sections of the trench axis seems more probable than a uniform regional downwarping of the areas around the core sites as a mechanism for isolating the turbidites^{2,4}. At the scale of a single fault, uplift can only occur as the result of reverse faulting (maximum compressive stress approximately horizontal and normal to the strike of the fault). Uplift in the trench is thus attributed to horizontal compression from converging, colliding

plates (the dip of the descending oceanic plate is generally 5° or less in the trench and is ignored in our simple model). If all vertical motion is a consequence of horizontal plate convergence and occurs along a single reverse fault (the simplest model), then simple trigonometry gives a minimum dip angle for the fault. By the geometry shown in Fig. 3, the amount of uplift (U), the angle of faulting (α) and amount of convergence (C) are related by: $U = C \tan \alpha$. Using $C = 10 \text{ cm yr}^{-1}$ and U values from Table 1, the calculated minimum angles of reversed faulting range from 16° to 66° (Table 1). Uplift rates and fault angles were calculated assuming continuous fault motion and episodic, represent minimum estimates. If fault movements were rapid and individual pulses of uplift would have been more therefore minimum fault angles would be greater.

Based on the above data, we propose the following model. Normal faults form earliest and are distributed over most of the trench outer slope down to the trench axis, a region approximately 40 km or more wide⁴. With present rates of plate motion, such features will persist a few hundred thousand years before being subducted. Recent reverse faulting in the trench axis and at least a partial decoupling of upper oceanic layer 2 from the

Fig. 3 The relationship between the convergence rate C , uplift rate U and the angle of reverse faulting α . $U = C \tan \alpha$. σ_1 is the axis of maximum compressive stress.

descending oceanic plate², usually along a narrow zone approximately 10 km wide, is indicated by the uplifted turbidites. Because they form in the trench axis, compressional features are relatively short-lived, of the order of 100,000 years or less at the present convergence rate. Further, the areal distribution of normal faults is at least four times that of reverse faults as compressional failure probably does not always extend seaward of the continental slope⁴. Lastly, the larger calculated fault angles (Table 1) support the idea that reversed motion may occur within the trench axis along the older steep normal faults².

i.d., internal diameter

If this model is applied to other trenches, it is apparent why reverse faulting has only just been postulated elsewhere^{11,12}. As actual fault planes are not visible on seismic reflection records, it is impossible to distinguish between a normal fault scarp and a steep reverse fault scarp without independent evidence of the kind provided by uplifted turbidite cores or, as in other detailed studies, by deep tow data and submersible observations^{11,12}.

Finally, the surficial stresses and faults within the trench axis are largely independent of whether the oceanic plate as a whole is under compressional or extensional stress. Even under overall compression flexure of the plate can cause local extensional stress and normal faulting with simultaneous large scale compressional faulting much further seaward of the trench^{1,13}.

We thank L. D. Kulm and K. F. Scheidegger for helpful discussions. Support was provided by the NSF/IDOE Nazca Plate Project.

Ecdysterone switches off fluid secretion at pupation in insect Malpighian tubules

ECDYSTERONE has been shown to stimulate fluid secretion in Malpighian tubules of adult male tsetse flies, suggesting a new function for steroid hormones in the control of insect excretory systems¹. I report here that ecdysterone has the reverse effect on larval tubules and switches off fluid secretion just before pupation.

Malpighian tubule fluid secretion was measured in larval and pupal male skipper butterflies (*Calpodethlius*, Lepidoptera: Hesperidae). Fluid secretion increases during the last larval stage to 2.02 nl min⁻¹ mm⁻¹ at P-48 (48 h before pupal ecdysis) but is reduced to zero by P-21 (Fig. 1) where it remains until halfway through the pupal stage. Fluid transport also stops at pupation in the Malpighian tubules of the monarch butterfly *Danaus* and the mealworm *Tenebrio* (Table 1), suggesting that it is a general phenomenon among holometabolous insects.

The titre of ecdysterone has been shown to increase in the blood before pupation in several insects²⁻⁴, including *Calpodethlius* (R. Dean *et al.*, personal communication). This suggested that ecdysterone may control the cessation of fluid transport. When ecdysterone is injected into a P-72 stage larva, fluid secretion is switched off within 24 h (Fig. 2). The direct action of ecdysterone on the Malpighian tubules was demonstrated by culturing tubules from a P-72 stage larva *in vitro* with or without 1 µg ml⁻¹ ecdysterone (2 × 10⁻⁶ M) for up to 48 h and then measuring the rate of fluid secretion in artificial haemolymph. As shown in Fig. 3, ecdysterone

Fig. 1 *In vitro* Malpighian tubule secretion rates at 0, 12, 21, 24, 33, 48 and 72 h before pupal ecdysis (P) in *Calpodethlius*. Secretion rates were measured on isolated tubules in artificial haemolymph (g l⁻¹: KCl 1.87, Na₂HPO₄ 0.71, MgCl₂ · 6H₂O 2.03, CaCl₂ 0.44, glucose 8.98, alanine 0.5, glutamic acid 0.37, glycine 2.26, histidine 2.03, lysine 1.04, serine 1.9, threonine 0.26, streptomycin sulphate 0.3, penicillin 0.03, phenol red 0.006) following the technique of Ramsay⁵. Each point is the average of about 20 tubules ± 1 s.e.m.

caused a significant reduction in fluid transport relative to controls within 12 h, and after 48 h, 13 of 19 experimental tubules were completely switched off.

Fluid secretion depends on energy from mitochondria⁵ and the diffusion of water along ionic concentration gradients in intracellular and extracellular channels^{6,7}; tubule ultrastructure was therefore examined to determine if changes in mitochondrial distribution or in apical/basal channel geometry were associated with the cessation of fluid transport. Electron microscopy revealed that the cells are extensively remodelled during metamorphosis, although the tubules remain intact and persist into the adult stage. Retraction of elongate mitochondria from the apical microvilli,

Fig. 2 Ecdysterone switches off fluid secretion within 24 h *in vivo*. 5 µg ecdysterone in 5 µl 100% ethanol (●) or 5 µl 100% ethanol (○) were injected into P-72 stage larvae (arrow). Secretion rates were subsequently measured using an *in situ* Malpighian tubule preparation in which decapitated and ligated animals were immersed in artificial haemolymph and dissected so that the tubules were left intact distally to the cryptonephridium. 8-18 tubules per point ± 1 s.e.m.

Fig. 3 Ecdysterone switches off Malpighian tubule fluid secretion *in vitro*. Tubules from a P-72 stage larva were cultured in a 50 : 50 mixture of artificial haemolymph-Graces culture medium containing $1 \mu\text{g ml}^{-1}$ ecdysterone (●) or $1 \mu\text{l ml}^{-1}$ ethanol (○). After various periods of time the tubules were transferred to artificial haemolymph and the rate of secretion was measured. Each point is the average of 15–20 tubules ± 1 s.e.m.

with their isolation and degradation in autophagic vacuoles, and a reduction in apical and basal channels are early events in the remodelling process. Both of these events are induced by ecdysterone *in vitro* (ref. 8 and unpublished data).

Fluid transport continues in Malpighian tubules at larval-larval moults (my unpublished data), even though a pulse of ecdysterone occurs in the blood to trigger moulting. This suggests that the inhibitory effect of ecdysterone is

Table 1 Loss of fluid secretion at pupation in different insects

Insect	Secretion rate in last larval stage			Secretion rate in early pupal stage		
		s.e.m.	n		s.e.m.	n
<i>Calpodes ethlius</i>	31.0 nl min^{-1}	1.2	20	0 nl min^{-1}	0	18
<i>Danaus plexippus</i>	5.7 nl min^{-1}	0.6	12	0 nl min^{-1}	0	12
<i>Tenebrio molitor</i>	0.25 nl min^{-1}	0.03	15	0 nl min^{-1}	0	15

modulated by some other factor such as juvenile hormone, since topical application of juvenile hormone to last larval stage *Calpodes* prevented the tubules being switched off at the larval-pupal moult.

Ecdysterone stimulates fluid secretion in tsetse fly tubules within minutes, suggesting a short-term physiological regulation¹. In contrast, the functional and structural changes described in this report are longer-term developmental processes which require hours or days. Also, unlike tsetse fly tubules, no short-term stimulation or inhibition of fluid secretion was observed within the first few minutes or hours following applications of $1 \mu\text{g ml}^{-1}$ ecdysterone to larval or adult *Calpodes* Malpighian tubules.

Difficulties in auditory organisation as a possible cause of reading backwardness

LEARNING to read and write involves auditory perception, for the child must learn how different kinds of sounds are written. It might seem, however, that although auditory perception is essential to reading, it would not be a significant source of difficulty, for, apart from a few exceptional cases, most children who have difficulties with reading can hear perfectly well, and can discriminate and understand the words which they signally fail to read¹. But discriminating words is not the only aspect of audition involved in reading. The child must also be able to group together words which are different but which have sounds in common. If he is to learn the rules of reading and writing he must understand that 'hat', 'cat' and 'mat', though different, nevertheless have a sound in common. We report here results which suggest that difficulties in this kind of grouping may be a significant source of difficulty in learning to read.

We compared a large group of children of normal intelligence, but 18 months or more behind the average reading skill for their age, with a group of younger children also of normal intelligence, whose reading skills were normal for their age and were the same as those of the backward readers. Details of the two groups are given in Table 1. Although the two groups were approximately equal in reading ability and were both of normal intelligence for their age, the backward readers were on average over three years older than the other group.

This is a novel kind of comparison and our reason for making it was to distinguish between cause and effect. The vast majority of studies of reading backwardness² and all the studies of auditory perception in backward readers³ compare backward with normal readers of the same age and intellectual level, the only difference between the groups being in how far they have learned to read. The trouble with this traditional design is that any difference which is found between backward and normal readers might just as well be the result of the former group's limited experience in reading. But if, as in our design, the two groups have reached the same reading level, and yet the backward readers are worse on a perceptual task, the fact that the two groups have the same reading ability as one another rules out the possibility that the backward readers' perceptual failure is merely the result of a lack of reading experience.

The method which we used in experiment 1 to test the grouping of sounds was to say four monosyllabic words to them. Three of the words had a sound in common which the fourth did not share. The child had to say which was the odd word out. There were three series, each with six trials (18 trials in all). In one series, all four words always had the same middle phoneme, but the last two phonemes were the same in three of the words while the odd one word had a different final phoneme (for example, weed, peel, need, deed). Another series was the same except that the middle phoneme was different in the odd word (for example, nod, red, fed, bed). In the third series, three words had the same opening phoneme while the odd one did not (for example, sun, see, sock, rag). The position of the odd word varied systematically in all three series.

We ensured that all the children understood and could perform the oddity task in practice trials, and we also eliminated forgetting words as a cause of failure, by preliminary trials in which children were given four words at a time and asked to recall them. We discarded two backward readers who consistently failed in these trials; all the others made virtually no memory errors. We took great care to pronounce each word with the same emphasis in order not to give the child any additional cue to the correct word. The experimenter also always hid her mouth from the child's view with a card, so that

Table 1 Details of the two groups

	N	Age		IQ (WISC)		Reading age (Neale)		Spelling age (Schonell)	
		Mean	Range	Mean	Range	Mean	Range	Mean	Range
Backward readers	60	10 yr 4 mth	8 yr 4 mth–13 yr 5 mth	108.7	93–137	7 yr 7 mth	6 yr–9 yr 4 mth	6 yr 10 mth	5 yr–8 yr 9 mth
Normal readers	30	6 yr 10 mth	5 yr 8 mth–8 yr 7 mth	107.9	93–119	7 yr 6 mth	6 yr–9 yr 2 mth	7 yr 2 mth	5 yr 1 mth–10 yr 2 mth

the shape of her mouth would not provide any additional cue for any of the children.

This experiment (Table 2) produced a startling difference between the two groups, the backward readers being markedly worse than the normal group in all three series. Putting the series together, 91.66% of the 60 backward readers made errors and 85% made more than one error. Only 53.33% of the 30 normal readers made any errors and only 26.66% more than

difference between backward and normal readers in categorising sounds was not due to the fact that we sometimes unconsciously emphasised one word more than another, despite our attempts not to do so. This evidence came from experiment 2, with the same children. They were given 10 words spoken successively (dish, car, boat, train, ball, mouse, dog, rake, truck, tent), and asked each time to produce a word which rhymed with each of these words. Here no extraneous cues of emphasis could possibly provide the correct answer.

Again, despite their superior age and overall intellectual ability, the backward readers were by far the worse of the two groups (Table 4), 38.33% of the former group and only 6.66%

Table 2 Mean error scores (out of 6) in experiment 1

Series	Odd word	Backward readers		Normal readers	
		N	s.d.	N	s.d.
1	Last letter different	60	1.15	30	0.17
2	Middle letter different	60	1.43	30	1.11
3	First letter different	60	1.49	30	0.37
		60	2.62	30	0.99
		60	2.26	30	0.67
		60		30	1.188

one. This difference is all the more remarkable, given that the backward reading group, being older by an average of 3½ years, was actually of a considerably higher intellectual level than the normal reading group. We suggest that many backward readers may be held back by a particular difficulty with organising sounds.

Although the backward readers were worse on all three series ($F: 32.499$; $d.f. 1,88$; $P < 0.001$ in an analysis of variance), they were at a particular disadvantage to the normal readers with

Table 4 Number in each group producing failures in experiment 2

	Total N	No. of failures									
		0	1	2	3	4	5	6	7	8	9
Backward readers	60	37	4	4	4	2	2	2	2	0	0
Normal readers	30	28	1	0	0	0	1	0	0	0	0

of the latter failing to produce a rhyming word in one or more trials. This task was probably easier than the earlier oddity test, since in both groups more children succeeded on every trial. But the relative failure of the backward readers in the second experiment is striking confirmation of their difficulty with categorising sounds. Overall, our results strongly suggest that this difficulty could be an important cause of reading failure.

Table 3 Division of the two groups into those making one or no errors and those making more than one error in experiment 1

N	Backward readers		t test of the difference	Normal readers		t test of the difference
	One or no errors	More than one error		One or no errors	More than one error	
	9	51		22	8	
Mean age	10 yr 6 mth	10 yr 3 mth	0.59	7 yr 1 mth	6 yr 4 mth	2.25*
Mean IQ	112.55	108.06	NS	109.73	102.87	2.63*
Mean reading age	7 yr 11 mth	7 yr 6 mth	1.51	7 yr 9 mth	6 yr 8 mth	2.91†
Mean spelling age	7 yr 4 mth	6 yr 9 mth	2.05*	7 yr 6 mth	6 yr 4 mth	2.41*

* $P < 0.05$

† $P < 0.01$

the series in which three of the four words had the same opening phoneme ($F: 4.28$; $d.f. 2,176$; $P < 0.05$). The relationship of this difficulty with the first phoneme to these children's problems with reading and writing should be investigated.

The large size of our groups enabled us to distinguish between those children who made more than one error over the three series and those who made only one error or none at all (Table 3). A clear developmental trend was found among the normal readers, as those who made one or no errors were significantly older and had significantly higher intelligence quotient (IQ) scores, and reading and spelling ages. However no such trend was found among the backward readers; here the only significant difference was that the few children who made one or no errors had a significantly higher spelling age than the rest. This suggests that difficulties in organising sounds may have particularly harmful effects on spelling among backward readers.

We needed further evidence to demonstrate that the large

Effect of gene dosage on expression of mitochondrial malic enzyme activity in the mouse

THE region of chromosome 7 in *Mus musculus* in which the albino (*c*) locus is located is of special interest because it is involved in deficiencies¹⁻⁶, a duplication^{7,8}, and X-autosome translocations⁹⁻¹¹. The structural gene (*Mod-2*) for mitochondrial malic enzyme (MOD-2) maps about 1 centimorgan (ref. 12) to the distal side of *c*, and has been shown by genetic experiments^{4,5} to be deleted in certain lethal albino mutations. Over 30 independently isolated homozygous lethal *c*-locus mutations have been recovered and characterised at Oak Ridge. In this report we have compared the level of MOD-2 expression in animals heterozygous for lethal *c*-locus mutations (*c^{ch}/c**) with that of their *c^{ch}/c^{ch}* littermates in order to clarify the precise

Fig. 1 Elution of heart malic enzymes from DEAE-cellulose. *a*, Total heart; *b*, heart mitochondria. Hearts from BLH mice were homogenised in HB:0.25 M sucrose, 0.05 M Tris-HCl (pH 7.5), 0.025 M KCl, 0.005 M MgCl₂, 100 µg ml⁻¹ heparin and 0.001 M phenylmethylsulphonylfluoride (PMSF). The homogenate was centrifuged for 10 min at 500g. In *a*, this supernatant was brought to 1% Triton X-100 and dialysed overnight against buffer A:0.1 M Tris-HCl (pH 8), 20% glycerol, 0.001 M MgCl₂, 0.001 M PMSF, 0.001 M dithiothreitol and 0.1% Triton X-100. The dialysed extract was centrifuged for 30 min at 30,000g and the supernatant was applied to a column (1 × 15 cm) of DE-52 cellulose (Whatman) that had been equilibrated and washed with buffer A. Elution was carried out with a linear gradient of KCl (0–0.2 M) in buffer A. Fractions of 5 ml were collected from which 0.2-ml aliquots were assayed for malic enzyme activity in a reaction mix containing 0.04 M triethanolamine-HCl (pH 7.5), 0.004 M MnCl₂, 0.00023 M NADP and 0.001 M K-malate (pH 7.6). The reduction of NADP was monitored by the increase in A₃₄₀ on a recording spectrophotometer maintained at 26°C. One unit of malic enzyme reduces 1 µmol NADP per min. In *b*, a mitochondrial pellet was prepared from the 500g supernatant by centrifugation for 5 min at 7,700g. The pellet was then washed twice with HB by centrifugation and was lysed in buffer A containing 1% Triton X-100. Chromatography on DEAE-cellulose was carried out as above after dialysis against buffer A and centrifugation. The arrow indicates the expected elution position of the first peak.

Fig. 2 Elution from DEAE-cellulose of heart malic enzymes from *c^{ch}/c^{ch}* mice (*a*) and from *c^{ch}/c^{ch}** littermates (*b*). Extracts were prepared from *c^{ch}/c^{ch}* and *c^{ch}/c^{ch}19DTR* mice as described in Fig. 1*a*. Chromatography and enzyme assays were carried out as in Fig. 1.

quantitative effect of gene dosage on the expression of enzyme activity in this system. We have shown that enzyme activity is linearly related to gene dosage in both heart and kidney. The data demonstrate that four out of seven complementation groups of *c** mutations are most simply explained as deficiencies that include *Mod-2*.

The specific activity of MOD-2 was determined in mitochondrial pellets prepared from homogenates of whole hearts. For purposes of dosage measurements it was essential to determine what proportion of malic enzyme activity in the mitochondrial fraction was MOD-2. Figure 1*a* shows the gradient elution profile from DEAE-cellulose of total heart malic enzyme, whereas Fig. 1*b* shows the elution of mitochondrial malic enzyme. It is clear that only the later-eluting of the two distinct peaks in Fig. 1*a* was associated with the mitochondrial fraction. Thus, our assays measured only a mitochondrial form of malic enzyme. Evidence that this second peak was in fact MOD-2 is shown in Fig. 2. In this experiment, whole heart homogenates were prepared from *c^{ch}/c^{ch}* and *c^{ch}/c^{ch}19DTR* mice, which were then chromatographed on DEAE-cellulose. The specific activity of mitochondrial malic enzyme in the *c^{ch}/c^{ch}19DTR* heterozygotes is about half that in *c^{ch}/c^{ch}* littermates (see Table 1). The striking decrease in peak II activity in heterozygotes is evident in Fig. 2*b*. We concluded that valid quantitative comparisons of MOD-2 activity could be made between mitochondrial fractions isolated from the hearts of *c^{ch}/c^{ch}* and *c^{ch}/c^{ch}** mice.

Table 1 presents the results of determinations of MOD-2-specific activities in heart mitochondrial fractions of *c^{ch}/c^{ch}* and *c^{ch}/c^{ch}** mice from 32 independently isolated *c** mutant stocks comprising seven complementation groups. These groups clearly fall into one of two classes: those in which heterozygotes were found to have almost exactly half the specific activity of MOD-2 of their *c^{ch}/c^{ch}* littermates, or those in which MOD-2 expression in heterozygotes was indistinguishable from that found in *c^{ch}/c^{ch}* littermates. The former class (groups B, D, E and F) is likely to comprise deletions extending into or beyond the *Mod-2* locus,

whereas the latter class (groups A, A' and C) maintains a functional *Mod-2* locus. Statistical analysis showed highly significant differences between MOD-2 specific activities of c^{ch}/c^{ch} and c^{ch}/c^* animals in every case in groups B, D, E and F; whereas ratios obtained in classes A, A' and C were in no case significantly different from unity.

Table 2 shows the results of three experiments that examined the relationship between *Mod-2* gene dosage and the expression of MOD-2 activity in kidneys. Two stocks previously shown to have a 2:1 ratio of MOD-2 activity in the hearts of c^{ch}/c^{ch} versus c^{ch}/c^* littermates were used. Although insufficient numbers of animals were examined for purposes of statistical analysis, the proximity of the experimental results to the expected 2:1 ratio is evident.

The results of this study have demonstrated that the level of MOD-2 activity is directly proportional to the number of copies of *Mod-2* present in the deletion mutants examined. The use of purified mitochondrial fractions permitted the direct measurement of MOD-2 activity without a large background, of uncertain magnitude, of MOD-1 activity¹³. A series of measurements

made on mice carrying three copies of *Mod-2*, due to a duplication of part of chromosome 7 (refs 7 and 8), has shown that MOD-2 activity is linearly related to gene dosage when two or three copies of *Mod-2* are present (E.G.B. and L.B.R., unpublished). Experiments are in progress to measure MOD-2 activity in mice carrying one, two and three copies of *Mod-2* as progeny of one genetic cross [$Dp(c^{ch})/c \times c^{ch}/Df(c)$]. In a detailed study of the Oak Ridge *c*-lethal mutations, DeHamer⁶ was able to detect clear differences in the staining intensity of the MOD-2 band on starch gels from c^{ch}/c^* and c^{ch}/c^{ch} animals in 23 of the 30 stocks examined, indicating that the *Mod-2* locus was deleted in these mutants. No differences in MOD-2 activity were noted on gels that were run of extracts prepared from c^{ch}/c^{ch} and c^{ch}/c animals (where *c* is a viable albino mutation and, presumably, not a deletion). Quantitative data on the expression of MOD-2 on gels were not obtained.

Our quantitative determinations were totally in agreement with the starch gel patterns obtained by DeHamer⁵, whose results were used in confirming the deficiency nature of most of the *c*-lethal mutations¹ in orientating the complementation map

For these experiments, pairs of littermates of like sex were used; that is, activities were determined for a set of c^{ch}/c^{ch} animals, each of which had a littermate of like sex, but of genotype c^{ch}/c^ , whose activity was measured in the same experiment. All determinations on a given stock were made in one day, except for c^{ch}/c^{ch} , 202G, 112K, 1FDFoHr_c, and 146G. Two of the four pairs assayed in stock 3R60L were not littermates, but were of like sex.

†Specific activities are given as units per mg protein. The unit is defined in Figure 1, in which the assay is also described. Mitochondrial pellets were lysed on ice in 0.05 M Tris-HCl (pH 7.5), 0.025 M KCl, 0.005 M MgCl₂, 0.1% 2-mercaptoethanol, and 1% Triton X-100, then centrifuged at 10,000g for 10 min. The supernatant was assayed for enzyme activity and protein. Protein was measured by the method of Lowry *et al.*¹¹.

‡65K and 112K occurred as a cluster, presumably derived from a single irradiated spermatogonium, and are thus not independent mutations.

with respect to the genetic map² and in defining complementation group E (ref. 2). In contrast to the preliminary complementation map presented by Gluecksohn-Waelsch *et al.*⁶, the deficiency in stocks *c^{85K}* and *c^{112K}* (group E) does in fact include *Mod-2* (Table 1 and ref. 5).

Russell and DeHamer reported that progeny of B × E crosses are viable although not fully vigorous, and, on the basis of the starch gel results, concluded that MOD-2 activity was not required for survival. The present results, which indicate that there is only one copy of MOD-2 both in *c^{ch}/c^{B group}* and in *c^{ch}/c^{B group}* animals, indicate that, in fact, the viable *c^{B group}*/*c^{E group}* mice lack MOD-2 altogether. We were unable to detect any activity in mitochondrial pellets prepared from *c/c* progeny of a B × E cross, thus confirming this inference.

Table 2 Specific activity of MOD-2 in kidney mitochondria of *c^{ch}/c^{ch}* and *c^{ch}/c^{*}* animals

Stock	Specific activity		Ratio
	<i>c^{ch}/c^{ch}</i>	<i>c^{ch}/c[*]</i>	<i>c^{ch}/c^{ch}</i> : <i>c^{ch}/c[*]</i>
4PB (experiment 1)*	0.0095	0.0056	1.70
4PB (experiment 2)*	0.0097	0.0048	2.02
202G†	0.0170	0.0095	1.80

Kidney mitochondria were prepared as described in Fig. 1, and assays were carried out as described in Table 1.

*Kidneys from three animals of each class were pooled.

†Kidneys from four animals of each class were pooled.

Diamond and Erickson¹³ were unable to detect any significant difference in MOD-2 specific activity in kidney mitochondria from *c^{ch}/+* and *c^{*}/+* animals. The results shown in Table 2 indicate that the expected quantitative difference between *c^{ch}/c^{ch}* and *c^{ch}/c^{*}* mice is found in kidney as well as in heart. We have noted that, in contrast to results with heart mitochondrial fractions, about 20% of malic enzyme activity in extracts of crude mitochondrial pellets from kidney chromatographs in the position of MOD-1. This is most likely due to cytoplasmic contamination. The data in Table 2 were obtained from preparations that were carefully prepared and washed before assay. Perhaps more relevant to dosage studies of MOD-2 in kidney is the fact that the reaction consistently deviated from linear kinetics after about 2 min, unlike the heart extracts. Thus, determinations were made in our study on the basis of initial velocities only.

Eicher and Coleman¹² have clearly demonstrated the expected dosage effect on MOD-2 expression in male mice carrying three copies of MOD-2 due to an unbalanced translocation [T(X;7)1 Ct]. Their data on females, however, are not in agreement with simple hypotheses assuming a linear gene dosage effect due to the random inactivation of one X chromosome. The basis of these inconsistencies with the linear gene dosage–gene product relationship in the MOD-2 system remains to be explained.

Naturally occurring respiratory deficient *Candida slooffii* strains resemble *petite* mutants

CYTOPLASMICALLY inherited respiratory deficient mutants termed *petites*, were first described in baker's yeast over 20 years ago¹. Since then in laboratory studies several species of yeast have been shown to give rise to respiratory deficient mutants^{2,3}. However, although some respiratory deficient (obligatory fermentative) yeasts have been found in nature³, it is not clear whether these species are the result of cytoplasmic (*petite*) or chromosomal lesions⁴ because no suitable genetic tests are available. Nevertheless it is known that *petite* mutants of both *Saccharomyces cerevisiae*⁵ and *Torulopsis glabrata*⁶ have large deletions from their mitochondrial DNA with each independent isolate having a unique circular DNA size profile which can be regarded as a 'fingerprint'. By contrast chromosomal or segregational mutants have intact and functional mitochondrial DNA, as shown by genetic tests^{3,7,8}. Therefore it seemed possible that the type of lesion in naturally occurring respiratory deficient species could be determined by circular DNA profile analysis. Using this method, we show here that three independently isolated strains of *Candida slooffii* resemble *petite* mutants.

C. slooffii is a naturally occurring respiratory deficient yeast originally obtained from the anaerobic environment of horse intestine but which has since been found in the guts of several other animals⁹. This yeast has been confirmed as lacking respiration; in addition, it has been shown to lack cytochrome *aa₃*, to have poorly defined mitochondrial profiles¹⁰ and to never revert to respiratory competent forms.

Independently isolated *C. slooffii* strains 2419, 2783 and 4068 were obtained from Centraalbureau voor Schimmelcultures, Delft. Total cellular DNA was prepared as detailed in Fig. 1 and analysed by buoyant density centrifugation. Main band DNA of strain 2419, the type strain and representative of all three strains, has a buoyant density of 1.6915 g cm⁻³ in agreement with a previous report for *C. slooffii*¹¹. On the heavy side of the main band there is a small peak of density 1.7065 g cm⁻³ which is also present in the other two strains. By analogy with *S. cerevisiae* this peak probably represents ribosomal DNA¹². On the lighter side of the main band there is a peak of density 1.6785 g cm⁻³. This light buoyant density DNA is the only component present in particles which band in a sucrose gradient in an identical position to similarly prepared mitochondrial profiles from *petite* mutants of *S. cerevisiae*¹³.

Additional evidence supporting the belief that the light buoyant density DNA in *C. slooffii* is mitochondrial in origin comes from studies using ethidium bromide. On treatment of strain 2419 with this drug, cultures are obtained which completely lack the light buoyant density component (Fig. 1). Similarly the intercalative dye, ethidium bromide, causes the complete elimination of mitochondrial DNA in *S. cerevisiae*^{14,15} and *T. glabrata*⁶. Indeed, drug-induced selective elimination of light buoyant density DNA in *petite* positive yeasts is a widely accepted diagnostic criterion for mitochondrial DNA.

When circular DNA is prepared from mitochondrial-like particles of the three *C. slooffii* cultures as detailed in Fig. 2 a single light buoyant density peak is found in each of the strains. However, each circular DNA has a different buoyant density which ranges from 1.680 to 1.674 g cm⁻³.

Confirmation that these circular DNAs are different was obtained by electron microscopy which showed that each

Fig. 1 Buoyant density traces in CsCl of DNA from *C. slooffii* strain 2419. *a*, Total cellular DNA; *b*, DNA from purified mitochondria-like particles and *c*, total cellular DNA from a culture isolated after euflavine treatment. The third gradient, containing 8.7 μ g DNA, was deliberately overloaded in an attempt to detect the light buoyant density component. Cultures were grown at 37 °C in 2% glucose, 1% yeast extract (Oxoid), 0.5% peptone (Oxoid), mineral salts¹⁹ and vitamins²⁰. Cells were converted to spheroplasts by incubation in support buffer (0.9M sorbitol, 0.02M imidazole-HCl pH 6.4, 1 mM EDTA) using a cell wall digesting enzyme mixture (1 g Driselase (Kyowa Hakko Kogyo) to 50 g wet weight of cells). Driselase was removed by two washes in support buffer and cells were lysed by the addition of sarkosyl to a final concentration of 2%. Lysed preparations were added to CsCl-ethidium bromide (as detailed previously¹³) and centrifuged for 44 h, at 10 °C, 48,000 r.p.m. in a Beckman 50 Ti rotor. DNA was visualised by ultraviolet excited fluorescence of intercalated ethidium bromide, extracted by side puncture of the tube and the dye removed by extraction with isoamyl alcohol. Buoyant densities were determined in the Spinco Model E analytical ultracentrifuge operated at 44,000 r.p.m. using *Micrococcus luteus* DNA of density 1.731 g cm⁻³ as a marker. Mitochondrion-like particles were obtained by gentle breakage of spheroplasts by passage through a French press at 2,000 lb/in². After removal of unbroken cells, debris and nuclei by successive centrifugations at 1,200g and 2,500g for 5 min in the Sorvall SS 34 rotor mitochondrion-like particles were collected by centrifugation at 8,500g for 20 min. The sedimented particles were resuspended in support buffer and layered onto linear sucrose gradients (25 g sucrose + 75 ml of 0.01 M EDTA, 0.01 M Tris-HCl pH 7.0; 55 g sucrose + 45 ml solvent) which were centrifuged at 25,000 r.p.m. for 1 h at 10 °C in the Beckman SW27 rotor. The particulate band in the middle of the gradient was extracted by side puncture, diluted with 3 volumes of support buffer and the particles collected by centrifugation. DNA was then isolated as outlined above. Treatment of *C. slooffii* strain 2419 with euflavine was performed as previously detailed^{1,4} by drawing a loop of culture across a drop of the drug (10 mg ml⁻¹) which had dried into agar containing the medium described above. After 2 d at 37 °C cells from the margin of growth were streaked away from the drug. This procedure ensures that individual colonies are obtained which arise from cells exposed to the highest concentration of euflavine compatible with survival.

preparation has a unique circular DNA size profile (Fig. 3). Strain 2419 has a clearly defined major length class at 0.56 μ m with smaller peaks at 1.28 and 1.76 μ m possibly representing oligomeric forms. A similar situation occurs in strain 4068 with a size class at 0.70 μ m and a possible dimeric form at 1.36 μ m. However, strain 2783 has an entirely different profile which is probably heterogeneous for several overlapping size classes. These results showing that each of the three isolates of *C. slooffii* has circular DNA differing both in buoyant density and circular size profile are therefore directly analogous to results obtained from independently derived *petite* mutants of both *S. cerevisiae* and *T. glabrata* as discussed above.

Although these results cannot exclude the possibility that the three strains of *C. slooffii* are double mutants harbouring chromosomal lesions for respiratory deficiency they do indicate that the mitochondrial DNA has suffered large deletions and that each strain is independently derived. In these respects they resemble true *petite* mutants.

On the basis of the above results, we suggest that *petite* mutants of many yeast species, rather than being laboratory curiosities, may indeed be widespread in habitats which do not select for respiratory competence. Other naturally occurring respiratory deficient yeasts which are likely *petite* mutants are *Torulopsis pintoalopesii*¹¹, *Torulopsis lactis-condensi*^{2,16} and *Schizosaccharomyces japonicus* variety *versatilis*^{2,17,18}.

Our results also indicate that the *C. slooffii* strains continue to harbour DNA that has no apparent function and which can be eliminated without affecting their viability. Although the continued replication of functionless DNA seems anomalous the cells probably have no means of preventing it.

Fig. 2 Buoyant density traces in CsCl of closed circular DNA from three strains of *C. slooffii*. Circular DNA was obtained as detailed previously^{13,21} by centrifugation in CsCl-ethidium bromide of a sarkosyl lysate of a membrane enriched fraction obtained after breaking cells in a Braun homogeniser. The closed circular DNA was freed from ethidium bromide by extraction with isoamyl alcohol, dialysed against 0.015 M NaCl, 0.0015 M Na citrate pH 7.0 and buoyant densities determined in the Spinco model E analytical ultracentrifuge. Circular DNAs from strains 2419 (*a*), 2783 (*b*) and 4068 (*c*) have buoyant densities of 1.6785, 1.680 and 1.674 g cm⁻³ respectively. *Micrococcus luteus* DNA of density 1.731 g cm⁻³ is a marker.

Fig. 3 Length distributions of relaxed circular DNA molecules from the closed circular DNA preparations of the three *C. slooffii* strains as observed in the electron microscope. The peaks indicated by the numerals have numbers and mean lengths of: a, strain 2419; 1, $n = 77$, $l_{\text{mean}} = 0.56 \pm 0.08 \mu\text{m}$; 2, $n = 13$, $l_{\text{mean}} = 1.28 \pm 0.09 \mu\text{m}$; 3, $n = 4$, $l_{\text{mean}} = 1.76 \pm 0.03 \mu\text{m}$; b, strain 2783; 1, $n = 119$, $l_{\text{mean}} = 0.19 \pm 0.04 \mu\text{m}$; 2, $n = 211$, $l_{\text{mean}} = 0.34 \pm 0.04 \mu\text{m}$; 3, $n = 97$, $l_{\text{mean}} = 0.50 \pm 0.03 \mu\text{m}$; 4, $n = 75$, $l_{\text{mean}} = 0.67 \pm 0.05 \mu\text{m}$; 5, $n = 44$, $l_{\text{mean}} = 0.84 \pm 0.04 \mu\text{m}$; 6, $n = 49$, $l_{\text{mean}} = 1.02 \pm 0.05 \mu\text{m}$; 7, $n = 26$, $l_{\text{mean}} = 1.20 \pm 0.04 \mu\text{m}$; c, strain 4068; 1, $n = 72$, $l_{\text{mean}} = 0.70 \pm 0.06 \mu\text{m}$; 2, $n = 29$, $l_{\text{mean}} = 1.36 \pm 0.08 \mu\text{m}$. The procedure for visualisation of the DNA was as described previously²¹.

Toxicity of diphtheria toxin for lymphoblastoid cells is increased by conjugation to antilymphocytic globulin

THERE is a pressing need in medicine for cytotoxic agents with tissue specificity. It may be possible to produce such agents by conjugating cytotoxic materials, themselves lacking inherent specificity, to antibodies directed against surface antigens peculiar to target cells. Various agents, including cytotoxic drugs¹⁻⁷, radioactive materials⁸, radiosensitising agents⁹ and enzymes¹⁰⁻¹¹ have been covalently coupled to antitumour antibodies in attempts to produce such antitumour agents but so far these have not consistently produced cures in tumour-bearing animals. We, like others¹²⁻¹⁶, have chosen to use diphtheria toxin because we consider that the paucity of tumour-specific antigens, accentuated, perhaps, by their restricted accessibility in solid tumours, necessitates the use of the most potent cytotoxins available.

The mode of action of diphtheria toxin is thought to involve the entry into a cell of the toxic 'A' chain following an interaction of its 'B' chain with receptors on the plasma membrane^{17,18}. Once inside the cell the 'A' chain terminates protein synthesis by enzymatic inactivation of peptidyl-tRNA translocation factor, EF-2 (ref. 19).

Moolten *et al.*¹⁴ covalently coupled diphtheria toxin to antibodies directed against SV40-induced antigens and produced a conjugate that exhibited a 2.2-fold greater 'specific toxicity' for SV40-transformed tumour cells *in vitro* than a conjugate of normal immunoglobulin. In spite of this small differential toxicity, the conjugate prolonged the life of, and occasionally cured, hamsters bearing an SV40-induced lymphoma. The fact that these workers used glutaraldehyde to couple toxin to antibody might explain why the conjugate only possessed marginal differential toxicity *in vitro* since this coupling agent is likely to have formed intra-chain bonds within the toxin molecule, thus preventing the 'A' chain from dissociating from the 'B' chain and penetrating into the cell. Here we report a new chemical coupling procedure which avoids the formation of intra-chain bonds in the toxin molecule. Using this method we have prepared a conjugate of diphtheria toxin and antilymphocytic globulin which can kill lymphoid cells at less than one-thousandth of the dose necessary for nonconjugated toxin.

Anti-human lymphocytic globulin (ALG) was raised by injection of a human lymphoblastoid cell line WRL7 into a horse and the IgG fraction of the serum was purified by conventional methods²⁰. The target cell was CLA4, a human lymphoblastoid cell line initiated by Dr M. Steel from cord blood leukocytes. The limit of binding of the ALG to the CLA4 cells as detected by indirect immunofluorescence was 0.012 mg ml⁻¹.

Fig. 1 Gel filtration on Sephadex G-150 of the products of reaction between diphtheria toxin and the chlorambucil-ALG conjugate. The eluate was monitored by absorption at 280 nm (—) and by radioactivity (c.p.m.) (....) derived from the ¹²⁵I-radiolabelled diphtheria toxin. Between fractions 20 and 31 was recovered a peak of radioactivity without concomitant absorbance due to the tendency of ¹²⁵I-radiolabelled toxin molecules to dimerise. Chlorambucil (7.5 mg, Wellcome) was dissolved in 0.3 ml of a 1.15% (v/v) solution of triethylamine in tetrahydrofuran and to this was added 0.3 ml of a 1.13% (w/v) solution of butyl chloroformate in dioxan. After stirring at 4 °C for 30 min a precooled solution of ALG (50 mg) in 5 ml of borate buffer (0.05M, pH 9) containing 1.7% NaCl and 1.4 ml dioxan was added. After stirring at 4 °C for a further 90 min, the solution was applied to a Sephadex G-25 column (1.6 × 40 cm) maintained at 4 °C and eluted with saline-borate buffer. The protein eluate was concentrated to 2.5 ml by ultrafiltration (Amicon) at 4 °C and 1 ml of the concentrate added to 1.0 ml of diphtheria toxin (25 mg ml⁻¹) and 0.05 ml of ¹²⁵I-radiolabelled toxin. The mixture was stirred at 25–30 °C for about 30 h, centrifuged, and 0.7 ml of the supernatant applied to the Sephadex G-150 (superfine) column (1.6 × 90 cm).

Diphtheria toxin was purified from a filtrate of a culture of *Corynebacterium diphtheriae* by ammonium sulphate fractionation and chromatography on DEAE-Sephadex and Sephadex G-100²². The leucine incorporation by human fibroblasts was reduced by 50% following treatment with 10⁻⁸ mg ml⁻¹ toxin for 24 h. Comparable inhibition in human peripheral lymphoid cells was obtained using 10⁻⁴ mg ml⁻¹ toxin.¹²⁵I-labelled toxin was prepared²¹ and mixed with unlabelled toxin to provide a ready means of detection and assay.

To prepare the conjugates, chlorambucil was converted to a mixed anhydride which was reacted with ALG at 4 °C (detailed in legend to Fig. 1). The resulting ALG-chlorambucil conjugate was freed from unreacted chlorambucil by filtration on Sephadex G-25 and was then mixed with diphtheria toxin. The temperature was raised to 25–30 °C to activate the mustard groups of the chlorambucil, which could then react with toxin to produce ALG-toxin conjugates or with ALG to produce polymers. This procedure avoids the formation of the toxin polymers that are formed when conventional coupling methods are used.

The products of the coupling reaction were subjected to gel filtration on Sephadex G-150 with the results illustrated in Fig. 1. The constitution of the fractions is summarised in Table 1. The bulked fractions 13–16 were as capable as native ALG of binding to CLA4 cells (immunofluorescence titre 0.012 mg ml⁻¹ ALG) and were used in the subsequent testing. By comparison, fractions 4–12 possessed inferior ability to bind to, and a lesser cytotoxic effect on, CLA4 cells.

CLA4 cells were treated with diphtheria toxin or ALG-toxin conjugate for 1 h, washed five times to remove non-bound material and incubated for a further 23 h. Continuous incubation for 24 h in the presence of the agents was also carried out. Toxic effects were judged by the reduction in the incorporation of ³H-leucine into cellular protein during a 16 h pulse with the labelled amino acid at the end of the incubation period. The results of the experiment are shown in Fig. 2.

Given a 24 h exposure to 10⁻⁶ mg ml⁻¹ toxin the leucine incorporation into CLA4 cells was reduced by only 50% and on 1 h exposure the reduction was around 25% at the highest concentration of toxin used (10⁻³ mg ml⁻¹). By contrast, the ALG-toxin conjugate reduced leucine uptake by 50% at toxin concentrations of 10⁻⁶ mg ml⁻¹ on both 1 h and 24 h exposure. Thus by attachment to ALG, the cytotoxic effect of diphtheria toxin on 1 h exposure to CLA4 cells was increased more than 1,000-fold. ALG alone, although causing agglutination, did not affect leucine uptake. When ALG and toxin were used simultaneously but not chemically coupled no increase in toxicity occurred, thus the effects we describe are not due to synergism between toxin and antibody as has been demonstrated for other drug-antibody combinations^{23–27}.

In order to confirm that the increased toxicity of ALG-toxin compared to toxin alone was mediated by an antigen-antibody reaction an experiment was performed in which normal horse IgG, with no detectable ability to bind to CLA4 cells, was used in place of the ALG. The results are shown in Fig. 3. The IgG-toxin conjugate (molecular weight 180,000–240,000) was in fact less toxic for CLA4 cells than free diphtheria toxin, the effect being most apparent after exposure for 24 h when the difference in toxicity was around 50-fold.

There are several mechanisms which could account for the increase in toxicity of diphtheria toxin for CLA4 cells after its conjugation to ALG. One is that CLA4 cells possess far more antigenic sites for combination with antibody than receptors for toxin, so that the conjugate effectively concentrates toxin on the cell membrane. A numerical difference of this kind may not entirely account for the effect as cells washed after exposure to toxin for 1 h subsequently develop less severe signs of cytotoxic action than cells exposed for 24 h, whereas the toxic effects of the conjugate are not reduced by washing; this observation is compatible with the notion that the affinity of toxin for its receptor is less than that of antibody for antigen. Lastly, the fate of toxin taken into cells by pinocytosis is thought to be proteolysis by lysosomal enzymes^{27–28}; however, if a mechanism exists whereby the

†This figure is inflated by the presence of ¹²⁵I-toxin dimers (see legend to Fig. 1).

undegraded toxin can escape from an endocytic vesicle into the cytosol then the combination of divalent antibody to the toxin could promote its internalisation by capping²⁸.

The decrease in toxicity found with the IgG-toxin conjugate for CLA4 cells is presumably due to steric hindrance of the IgG with the toxin-receptor interaction. This is supported by our finding that both ALG-toxin and IgG-toxin were 50-fold less effective than toxin alone at inhibiting leucine uptake by human fibroblasts *in vitro*, a cell type to which neither ALG nor IgG bound. The reduction in nonspecific toxicity of diphtheria toxin after conjugation to immunoglobulin might possibly be reflected by a reduction in undesirable side effects *in vivo*.

By using a chemical coupling procedure designed to eliminate the risk of producing intra-chain linkages in the toxin molecule thereby placing no restriction on the freedom of the 'A' chain to penetrate the cell, we have produced conjugates with greatly enhanced toxicity for the target. We believe that this represents

Fig. 2 The effect of diphtheria toxin alone (○) or conjugated to ALG (fractions 13 to 16) (●) on the ³H-leucine incorporation by CLA4 cells, expressed as % of incorporation by untreated cultures. The CLA4 cells were suspended in Hanks' balanced salt solution containing 10% heat inactivated foetal calf serum; this medium is free from glutamine, a substance known to interfere with the cytotoxic activity of diphtheria toxin³¹. The suspension (1 × 10⁶ cells ml⁻¹) was distributed in 200 μl volumes into the wells of 96-well flat-bottomed microplates (Linbro). The cells were either *a*, incubated with toxins for 24 h at 37 °C or *b*, incubated with toxins for 1 h before washing five times and resuspending into fresh Hank's-serum medium for a further 23 h incubation. All cultures were resuspended after 24 h into 50:50 Dulbecco's-RPMI medium supplemented with 10% serum, glutamine (3 mM) and antibiotics and were then pulsed for 16 h with 1 μCi per culture of ³H-leucine (Amersham Radiochemicals, TRK 170, 58, Ci mmol⁻¹). Leucine uptake was measured as previously described³². Toxin added simultaneously with ALG (2.8 molecules ALG per molecule of toxin, equivalent to the ALG:toxin ratio in conjugate 13-16) had identical toxicity to that described for toxin alone in the figure. Vertical lines in the figure represent one standard deviation on geometric mean of triplicate determinations, unless smaller than the points as plotted.

Fig. 3 The effect of diphtheria toxin alone (○) or conjugated to normal horse IgG (molecular weight 180,000-240,000) (●) on the ³H-leucine incorporation by CLA4 cells, expressed as % of incorporation by untreated cultures. The CLA4 cells were exposed to the toxins for *a*, 1 h or *b*, 24 h. Other details as for Fig. 2.

a useful step towards the design of new chemotherapeutic agents.

We thank Dr B. Mikulski for her help in maintaining the CLA4 line and Mr J. S. Courtenay for supplying the antiserum. Role of cyclic GMP in the action of heat-stable enterotoxin of *Escherichia coli*

ENTEROTOXIGENIC strains of *Escherichia coli* elaborate two enterotoxins, a heat-labile toxin (LT) and a heat-stable toxin (ST), which cause diarrhoeal disease in humans¹; ST-producing *E. coli* cause diarrhoea in adult volunteers² and have been associated with epidemic diarrhoea in a nursery for the newborn³ and with sporadic adult diarrhoea among North American tourists to Latin America⁴ and the Navajo people in Arizona⁵. LT-producing strains are identified by the ability of culture filtrates to cause fluid accumulation in rabbit ileal loops at 18 h (ref. 6) or by morphological alteration of Chinese hamster ovary (CHO) cells⁷ or of Y-1 adrenal cells⁸. ST-producing strains are identified by the ability of culture filtrates to cause earlier fluid accumulation in rabbit ileal loops (peak accumulation at 6 h (ref. 6), or by fluid accumulation in the gut of the suckling mouse at 3 h (refs 9, 10). LT acts in a manner similar to cholera toxin (CT) by activating adenylate cyclase¹¹. The mechanism of action of ST is unknown, however. Culture filtrates of a strain of *E. coli* that produced both LT and ST caused immediate net fluid secretion in canine jejunal segments without the 1-h delay characteristic of the response to CT^{12,13}. In addition, culture filtrates caused an immediate increase in canine jejunal adenylate cyclase activity as measured by enzymatic generation of P³²-cyclic AMP from P³²-labelled ATP¹³, also in contrast to the delay in appearance of increased adenylate cyclase activity following exposure to CT¹². The possibility that the early effect of ST was mediated by changes in cyclic nucleotide concentrations was investigated; culture filtrates of ST-producing strains of *E. coli* caused increased cyclic GMP concentrations in rabbit intestinal tissue and

Fig. 1 Dose-response effect of 8BrGMP on suckling mouse fluid secretion at 60 min. Points represent means \pm s.e.m. of three or more groups of two to five mice representing a total of seven or more mice. Mice, aged 2-4 d were inoculated intragastrically with 0.1 ml of solutions containing 0.12-5 μ mol 8BrGMP per mouse.

Fig. 2 Time course of 8BrGMP effect on suckling mouse fluid secretion. Points represent means \pm s.e.m. of three or more groups of two to five mice representing a total of seven or more mice. ●, 8BrGMP; 1 μ mol per mouse; ×, 0.1 μ mol 8BrGMP per mouse; ○, control 8BrGMP (1 or 10 μ mol per mouse).

the cyclic GMP analogue 8BrGMP mimicked ST in magnitude and time course of intestinal fluid accumulation in both rabbits and suckling mice.

Two *E. coli* strains (B30-5 and B44¹⁴) which produced only ST were used and rabbit intestinal tissue levels of cyclic AMP and cyclic GMP were determined in biopsies taken after inoculation of ligated intestinal loops with culture filtrates of these strains. Mean mucosal cyclic GMP concentrations in intestinal segments exposed to filtrates of strains B30-5 and B44 for 20 min were over threefold greater than in control loops ($P < 0.02$, Table 1); cyclic AMP levels were not significantly different.

To determine if cyclic GMP analogues could produce intestinal fluid accumulation in the rabbit, ligated intestinal segments were inoculated with 8BrGMP; controls loops were inoculated with 8-Br-5'-GMP (8BrGMP). Ratios of intestinal fluid to segment length were significantly greater in loops exposed to 8BrGMP than in controls (Table 2). This volume/length ratio approximates the reported effect of ST at 2 h in this model⁶. As fluid secretion might have occurred as a result of increased tissue cyclic AMP levels secondary to inhibition of cyclic AMP phosphodiesterase by 8BrGMP¹⁵, the effect of 8BrGMP, 8BrGMP, and water on intestinal cyclic AMP levels was investigated. At 20 min and 2 h after loop inoculation, tissue samples were homogenised in trichloroacetic acid, extracted, and purified¹⁶ for determination of cyclic AMP levels. Tissue cyclic AMP levels in loops exposed to 1.25 mM 8BrGMP were not significantly different from control loops exposed to either 1.25 mM 8BrGMP or water at 20 min (24 ± 1 compared with 28 ± 2 pmol per mg protein) or at 2 h (24 ± 1 compared with 27 ± 2 pmol per mg protein). As in studies shown in Table 2, intestinal loop fluid accumulation expressed as volume/length ratios was significantly greater in loops exposed to 8BrGMP ($P < 0.02$) in these experiments.

To determine if cyclic GMP analogues would cause fluid accumulation in the suckling mouse assay used for detecting ST-producing strains of *E. coli*⁹⁻¹⁰, the response of suckling mice to 8BrGMP and 8BrGMP was investigated. The dose-response curve at 1 h (Fig. 1) shows that doses of 0.25 μ mol or greater produced significant fluid accumulation in the mouse gut compared with either normal saline or 5 μ mol 8BrGMP controls ($P < 0.05$). Using 1 μ mol 8BrGMP per mouse, the

Table 1 Rabbit intestinal cyclic nucleotide concentrations after 20 min exposure to culture filtrates of ST-producing and control *E. coli*

	ST strains	Controls
Cyclic GMP (fmol per mg protein)	1991 ± 422*	572 ± 62*
Cyclic AMP (pmol per mg protein)	34 ± 15†	18 ± 2†

Values are means ± s.e.m. of 7 observations with ST strains and 10 observations with control strains. Filtrates were prepared from 18 h cultures grown in casamino acids-yeast extract salts broth (CA-YE)¹⁹ in a roller drum at 37 °C; volumes of 1 ml were injected into 4–5 cm ligated segments of rabbit ileum as previously described⁹. Control loops were inoculated with sterile CA-YE broth or culture filtrates from nontoxicogenic *E. coli* strain 10405. Full thickness biopsies of each loop obtained 20 min after inoculation were promptly homogenised in 2 ml of chilled 6% trichloroacetic acid (TCA). Specimens were stored at –20 °C prior to centrifugation for removal of the pellet for protein determination by the Lowry method¹⁵. After ether extraction of the supernatant fraction, cyclic AMP and cyclic GMP concentrations were determined by radioimmunoassay^{16,17}.

* $P < 0.02$, student's *t* test.

†Not significant change.

time course (Fig. 2) indicated that significant fluid accumulation occurred by 60 min ($P < 0.01$) and became maximal by 2 h.

The response of both rabbit and suckling mouse intestine to 8BrGMP which mimics the action of culture filtrates of ST-producing strains of *E. coli* in these models and the significant increase in rabbit intestinal cyclic GMP levels after exposure to culture filtrates of ST-producing strains suggest that intestinal fluid accumulation induced by ST may be mediated through increases in intestinal guanylate cyclase activity. This possibility is consistent with the previous observation that canine intestinal adenylate cyclase activity was promptly elevated following exposure to culture filtrates containing ST¹³; in these experiments, adenylate cyclase activity was measured using the Krishna assay²⁰ which measures enzyme activity as a function of conversion of radiolabelled ATP to cyclic AMP. However, activated guanylate cyclase can convert ATP to cyclic AMP²¹ and might therefore be measured as adenylate cyclase activity in the Krishna assay.

That cyclic GMP might play an important part in the mediation of intestinal fluid secretion in humans with diarrhoea caused by ST-producing strains of *E. coli* is further supported by previous observations that a 2 mM solution of cyclic GMP increases the short-circuit current in the isolated toad bladder after a 3- to 5-min lag period following application to the serosal side of the membrane²². However, other studies have demonstrated that α -adrenergic and cholinergic agents may increase rabbit intestinal mucosal cyclic GMP levels while also increasing Na⁺ and Cl[–] absorption rather than secretion, but exogenous 8BrGMP failed to reproduce these effects²³. The possibility exists that multiple pools of cyclic GMP may be present in intestinal mucosal cells, as suggested for cyclic AMP²¹, and that changes in one of these compartments may effect electrolyte secretion. Further support for a possible secretory role for cyclic GMP is provided by the observation

that after cholinergic stimulation of guinea pig pancreatic islet cells, cyclic GMP increases promptly in both intracellular and extracellular phases, possibly mediating secretion of amylase²⁵. The location of intestinal cyclic GMP and guanylate cyclase activity has been demonstrated to be in the intestinal mucosal microvilli of the rat^{26,27}.

The association of increased intestinal mucosal concentrations of cyclic GMP with ST-induced intestinal secretion and the ability of 8BrGMP to mimic the effects of ST without concomitantly increasing tissue cyclic AMP levels in standard animal models suggests a role for cyclic GMP in the pathogenesis of ST-associated diarrhoea. These findings may suggest new approaches to the pharmacological control of diarrhoea caused by ST-producing strains of *E. coli*.

Note added in proof: Since this manuscript was submitted for publication, it has been learned that M. Field, L. H. Graf, Jr, W. J. Laird and P. L. Smith have found that an ST preparation increases electrical potential difference and guanylate cyclase activity in rabbit ileal mucosa (submitted for publication).

Table 2 Rabbit intestinal fluid accumulation after 2 h of exposure to 1.25 mM 8BrGMP and control (8BrGMP)

	Volume/length ratio (ml cm ^{–1})	
8BrGMP	0.29	0.03
8BrGMP	0.17	0.02

Values represent means ± s.e.m. of 10 observations with 8BrGMP and 6 observations with 8BrGMP. Student's *t* test: $P < 0.01$. One ml of 1.25 mM 8BrGMP was inoculated into approximately 4-cm ligated rabbit intestinal segments; controls were inoculated with 1.25–10 mM 8BrGMP. At 2 h, rabbits were killed with intravenous sodium pentobarbital and the ligated small intestinal segments removed. Segment lengths and fluid volumes were measured and volume/length ratios determined.

Induction of IgG production in human B lymphoblastoid cell lines with normal human T cells

THYMUS-DERIVED (T) lymphocytes play a critical part in the induction of B lymphocytes to antibody production¹, especially for conversion of IgM to IgG response². In humans, the presence of T lymphocytes is also essential for the induction of IgM or IgG production by pokeweed mitogen (PWM)-stimulated B lymphocytes^{3,4}. In many experiments it has been

shown that antigen-specific⁵ or nonspecific⁶⁻⁸ soluble factors from T cells, together with antigen or other inducers, for example, anti-immunoglobulin antibody, acting on B-cell surface receptors⁹, can also provide the stimulus for Ig production in B cells. However, the chemical nature of a B-cell acceptor for the T-effector molecule, the biochemical events responsible for the differentiation of B cells to Ig-producing cells, and the mechanism of the switch of transcription from μ chain to γ chain genes under the influence of T cells remain largely unknown. Heterogeneity of B-cell population in spleen, lymph node and blood has hindered the molecular analysis of immune phenomena. In this situation, B lymphoblastoid cell lines may be useful models for such analysis, since they may be arrested at certain phases of their differentiative history and if influenced by T cells or T-cell factors might permit incisive analysis of induction and switching of gene action at

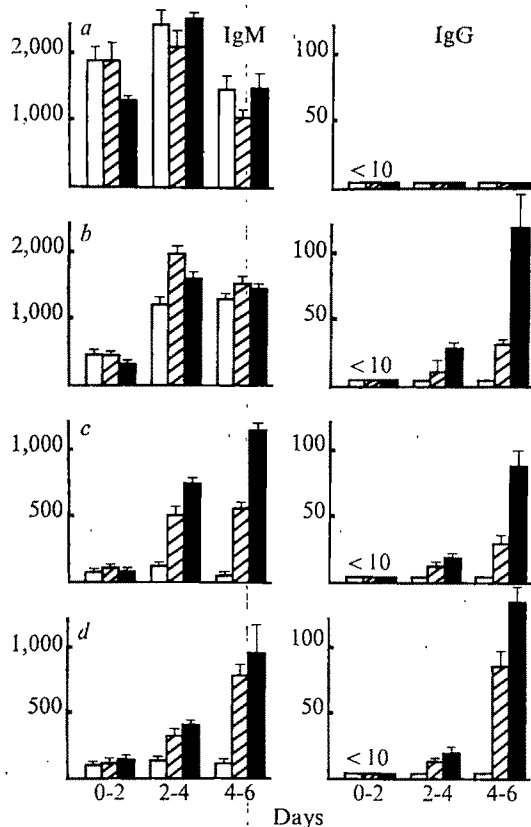

Fig. 1 Induction of IgG production in human B-cell lines by normal T cells and macrophage factors. B-cell lines were as described previously^{16,17}. They were maintained in RPMI 1640 medium containing 10% foetal calf serum and 5×10^{-5} M 2-mercaptoethanol. Experimental cultures were initiated in the same medium in triplicate in 0.2 ml volumes (Falcon 3040 microtest plates) containing 10^4 B cell lines (open bars), and where indicated 10^5 normal T cells (donor Y.N.) (hatched bars), or T cell plus 50% v/v macrophage factor (solid bars). Cultures were incubated at 37 °C in 5% CO₂. After 2, 4 and 6 d incubation, the plates were centrifuged, supernatants collected and assayed for IgM and IgG by a radioimmunoassay¹⁵. Fresh medium was added to the cultures after the samplings. T cells were purified from normal human blood lymphocytes by neuraminidase-treated sheep RBC rosette formation¹⁵, and contained less than 1% B cells (surface Ig⁺ cells by immunofluorescence). Macrophage factor was obtained from culturing J774.1 cell line¹¹ with $1 \mu\text{g ml}^{-1}$ LPS (type B, *Escherichia coli* 055:B5, Difco) for 24 h and dialysing the supernatant against culture medium. Supernates prepared without LPS or with LPS added at the end of 24 h were not active. Results are shown as IgG (right hand column) or IgM (left) ng ml⁻¹ (\pm 1 s.d.). The background sensitivity of the assays are 10 ng ml⁻¹ IgG and 20 ng ml⁻¹ IgM. Specificity is shown by failure to detect cross reactions using 10,000 ng ml⁻¹ heterologous antigen. Recovery of lymphoblast cells at day 6 was the same for cultures of B cells alone, of B cells with T cells, or of B cells plus macrophage factors, for all experiments. a, BM; b, RPMI 1788; c, Daudi; d, SB-cell line.

the molecular level. We report here the induction of IgG production or enhancement of IgM secretion in several human B lymphoblastoid cell lines with the help of normal T cells.

Five cell lines were studied for production of IgM and IgG when cultured alone, with normal human T cells, and with human T cells plus macrophage factors. Lines BM, RPMI 1788 and Daudi had IgM on the cell surface as well as in the cytoplasm when tested by immunofluorescence, and lines BM and RPMI 1788 continuously secreted IgM in the culture supernatant, but did not secrete any IgG molecules when tested by radioimmunoassay. Line SB had IgM and IgG on the surface and inside the cells, but secreted only small amounts of IgM. As shown in Fig. 1, there were several patterns of cell-line reactivity. Line BM produced only extracellular IgM even in the presence of T cells. On the other hand, coculture of lines RPMI 1788, Daudi or SB with T cells induced IgG production. In addition, T cells also significantly increased extracellular IgM levels in Daudi and SB cultures. The stimulation of IgG and IgM production induced by T cells was not due to increased growth of the cell line, since recovery of larger lymphoblastoid cells was not affected by the presence of T cells. In experiments with cell line WIL2.A3, neither IgM nor IgG was detectable in the medium in any conditions (data not shown).

We previously showed that supernates from 24-h cultures of macrophages could replace adherent cells in the nonspecific induction of mouse T killer cells to syngeneic or allogeneic tumour targets¹⁰. Supernates of the mouse macrophage line J774.1 (ref. 11), when stimulated with bacterial lipopolysaccharide (LPS), also replaced adherent cells in this system (data not shown). Macrophages are also known to produce factors stimulatory to antibody production by B lymphocytes¹²⁻¹⁴. Therefore, the J774.1 supernatant preparation following treatment with LPS was tested for stimulation of B lines. In all cases where T cell-dependent induction of IgG was observed, inclusion of the macrophage factors further stimulated IgG production about twofold. Macrophage factors alone, however, did not induce IgG production, showing that the presence of T cells is essential for the induction of IgG in these cell lines.

The IgG production observed could not have been due to contamination of the T-cell preparation with normal B cells. The T-cell population contained less than 1% of surface Ig-positive cells. No IgG or IgM was secreted when these cells were cultured alone or with PWM for 6 d at concentrations which optimally induce Ig secretion in unfractionated lymphocytes¹⁵. To further test for possible effects of normal B cell contamination, cultures were set up with RPMI 1788 cells plus purified T cells reconstituted with normal, syngeneic B cells (Table 1). The donor T cells used in this experiment do not induce RPMI 1788 to IgG production at 10^5 cell culture, but do induce them at higher numbers of T cells. Inclusion of 10^4 B cells resulted in the production of 17 ng ml^{-1} IgG at day 6. By contrast, with 4×10^5 T cells and 1×10^4 RPMI 1788 cells, $80 \text{ ng IgG ml}^{-1}$ was observed. Such amounts of IgG would

Table 1 Test for contamination of normal B lymphocytes in cell-line induction

Cell line (RPMI 1788) $\times 10^4$	T cells $\times 10^5$	B cells $\times 10^5$	IgG (ng ml ⁻¹)
1	0	0	< 8
1	1	0	< 8
1	2	0	38.5 ± 25.9
1	4	0	80.3 ± 24.9
1	1	0.1	17.3 ± 3.8
1	0	0.1	< 8

Cultures (0.2 ml) were initiated with 10^4 RPMI 1788 cells, various numbers of normal T cells (donor T.K.), and where shown, normal B cells to represent a 10% contamination of the T cells. Normal T lymphocytes were purified as in Fig. 1, and the T-depleted population was used as B cells (60% Ig⁺). Supernate IgG was determined after culture for 6 d.

Table 2 Increase of IgG-containing cells in cell lines cocultured with T cells

	% Of fluorescent-positive lymphoblastoid cells			
	Expt. 1 without T	Expt. 1 with T	Expt. 2 without T	Expt. 2 with T
SB	21	90	—	—
BM	4	22	—	—
RPMI 1788	—	—	8	22
BM	—	—	5	30

Cell lines (10⁴ per 0.2 ml) were cultured with or without 2 × 10⁵ normal T cells for 5 d. Intracellular IgG was stained with FITC-labelled F(ab')₂ fragment of rabbit anti-human γ-chain antibody. In each experiment 200–400 larger lymphoblastoid cells were counted.

require the presence of 4 to 5 × 10⁴ normal B cells, or a 10% contamination of the T-cell preparation, such contamination would have been easily detected.

Furthermore, the fluorescent staining of intracellular IgG showed an increase of IgG-containing B lymphoblastoid cells was caused by coculturing with normal T cells (Table 2). In these experiments, however, the increases of IgG-containing cells and the amounts of extracellular IgG were not parallel, that is, (1) almost 90% of SB cells were IgG-positive when cocultured with T cells but the amount of IgG produced in culture was far less than that observed in the culture of normal peripheral blood lymphocytes (PBL) with pokeweed mitogen (PWM), (2) IgG-containing cells were observed even in BM cells cocultured with T cells, in which extracellular IgG was not detected. The result suggested that IgG production was induced in these cell lines, but that these cells produced a small amount of IgG compared to normal IgG-producing cells.

As IgG production was induced by normal T cells without the presence of known T activators, it is possible that Ia-like molecules on the allogeneic B cell lines stimulated T cells to exert a helper activity. Induction of IgG in lines RPMI 1788, Daudi and SB occurred reproducibly in four experiments, as is shown in a typical experiment in Fig. 1, using two different T cell donors. However, T cells from certain donors were consistently superior to those of other donors in this assay, as shown in Table 3. All T-cell preparations showed similar helper function in pokeweed mitogen induction of self and allogeneic normal B cells. The differences in the influence of donor T-cell activity on B-cell lines may be due to the degree of matching of cell surface antigens at the major histocompatibility complex, or to the degree of stimulation by cell line Epstein-Barr virus antigens on cells of the B-cell line. Actually, in mixed lymphocytes reactions, mytomycin C-treated RPMI 1788 cells did not stimulate T cells from donors, H.K. or A.M., while T cells from donors Y.N., T.H. and T.K. showed a significant increase of ³H-thymidine uptake (stimulation

Table 3 Cell line induction by different donor T cells

T cells were purified from five different donors and assayed for induction of IgG production in line RPMI 1788 with or without macrophage factor, as in Fig. 1. The T cells cultured alone contained undetectable IgG (<8 ng ml⁻¹).

index 3.2–6.0) when stimulated with mytomycin C-treated 1788 for 5 d. The results may support the idea that T cells activated against Ia-like molecules on the allogeneic B-cell lines exert helper function so as to induce the switching from IgM to IgG production in B lymphoblastoid cell lines.

This experimental system should prove for the study of gene expression responsible for IgG synthesis under the influence of T cells.

Transplantation tolerance
induced in foetal mouse thymus *in vitro*

BURNET'S suggestion that self tolerance was gained during foetal life by elimination of self reactive clones of lymphocytes¹ has gained support from studies with lymphoid chimaeras prepared by injection of either foetal or neonatal animals with histoincompatible spleen cells², by injection of irradiated adult F₁ hybrid mice with parental-type bone marrow cells³, or by fusion of eight-cell-stage embryos⁴. However, in some situations active suppression by blocking factors⁵ or by suppressor T cells⁶ may account for the lack of reactivity in apparently tolerant animals, although it is likely that these mechanisms operate only when tolerance is incompletely induced⁷. We describe here an *in vitro* model for the study of transplantation tolerance and offer evidence that active suppression by regulatory T cells is not involved. Unresponsiveness to mixed lymphocyte culture (MLC)-stimulating determinants on histoincompatible cells was induced in foetal murine thymocytes in organ culture by incubation of foetal thymus, of 14-d gestation, in contact with mitomycin-treated fragments of adult allogeneic spleen (Fig. 1).

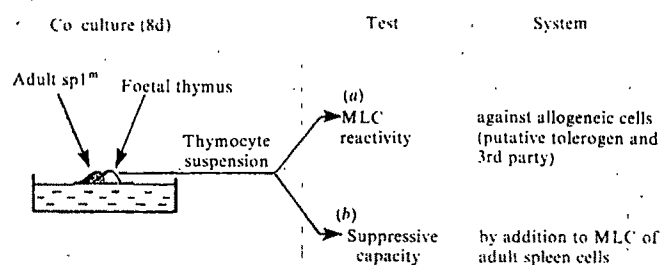

Fig. 1 Experimental protocol for tolerance induction and assay. *a*, MLC in a microculture system using 0.2 ml RPMI + 10% foetal bovine serum containing 2×10^5 each of cultured thymocytes (responder) and mitomycin-treated adult spleen cells (stimulator) in triplicate. Assayed after 4 d by an 18-h pulse of $1 \mu\text{Ci } ^{125}\text{IU}$ per culture, the c.p.m. being adjusted for decay of isotope. *b*, Suppressive effect of co-cultured thymus cells, on MLC of syngeneic adult spleen cells against the tolerated strain, tested by adding mitomycin-treated cultured thymus cells to responder cells in the ratio 1:2. The degree of suppression was expressed as percentage of MLC in the presence of the same number of syngeneic mitomycin-treated spleen cells. Suppression was controlled by sensitising suppressor cells by footpad injection of 2×10^7 allogeneic spleen cells, suppressive activity being optimal in the spleen of recipients 4 d later. Ratios of 1:1, 1:2 and 1:4 regulator: responder in MLC were plotted using the formula

$$\frac{\text{MLC ratio with activated suppressor cells} - 1}{\text{MLC ratio with control cells} - 1} \times 100 \%$$

control MLC response, when maximum suppression (to 35% of controls) was achieved using 1:2 regulator to responder ratio.

We have reported that MLC reactive cells can be generated from stem cells in organ culture*; cells reactive in allogeneic MLC against BALB/c and CBA/H adult spleen cells first appear after 4 d of culture of 14-d C57BL/6 foetal thymus. We report now that the appearance of these cells was unaffected by co-culture of foetal thymus with syngeneic spleen fragments (Fig. 1). But when foetal thymus

was co-cultured with allogeneic spleen fragments, MLC reactivity against the spleen donor strain did not arise, although reactivity against a third party strain was detectable (Table 1).

Furthermore, co-cultured thymus cells did not suppress the response of adult C57BL/6 spleen cells against CBA/H, the tolerated strain, when added in optimal proportions according to the assay of Rich and Rich¹⁰ (Table 1) (except for a low level of suppression in one experiment). Therefore it is unlikely that the generation of a population of suppressor cells in allogeneic co-culture accounts for the lack of MLC reactivity observed. Furthermore, Ig-bearing B cells have not been found in extensive surveys of cultured thymocytes and so in the absence of immunoglobulin secretion, antigen-antibody complexes are unlikely to operate in tolerance induction in this system. Tolerance was demonstrated in seven out of 19 attempts, the remainder giving equivocal results due to the lack of MLC reactivity even in control, syngeneic co-cultures. This lack of reproducibility in obtaining an MLC reaction is probably related to technical difficulties in setting up the experiments.

A more detailed analysis of the mechanisms of tolerance induction in the systems is under way. In particular we are investigating whether antigens of the spleen donor strain are present on the surface of co-cultured thymocytes as their presence may lead to reversible or irreversible blocking of subsequent MLC reactivity. As cells are washed well before the MLC assay we feel that blocking by antigen is unlikely to account for our results. In the absence of suppression, clonal deletion may be the mechanism underlying nonreactivity in this system.

When foetal thymus was cultured for 3 d before addition of allogeneic spleen fragments, MLC tolerance was not demonstrable because cells reactive against the spleen donor strain were generated, as in control cultures (Table 2). Furthermore, if the addition of spleen fragments was delayed by 1 d, tolerance was incomplete as residual MLC reactivity against the 'tolerogen' remained (Table 2). This

Conditions were identical to those described in Table 1 except that spleen fragments were added to foetal thymus after a delay of 1 and 3 d, respectively.

suggests that tolerance induction depends on events occurring early in organ culture, when differentiating lymphocytes are exposed to the tolerogen but before detectable numbers of MLC reactive cells have arisen. Therefore a thymocyte precursor may be the target cell for tolerance induction. This finding parallels the recent demonstration of the tolerogenic effect of antigen on immature B cells^{10,11}. Distinct and interacting subpopulations of T cells underlie graft rejection, and unresponsiveness in one or more of these subsets may be a necessary prerequisite to allograft acceptance. In neonatal mice lymphocyte-defined and serologically-defined determinants induce unresponsiveness in precursors of MLC reactive and cytotoxic T cells respectively¹², and the former provide the major barrier to the induction of transplanatation tolerance¹³. Therefore T-cell tolerance of MLC stimulating determinants seems to be the most stringent in induction requirements.

In conclusion, our results demonstrate unresponsiveness to MLC stimulating determinants in the absence of suppression, in thymocytes generated in organ culture of foetal mouse thymus. This represents an unprecedented investigation of T-cell tolerance induced within the thymic microenvironment during ontogeny *in vitro*.

Regeneration of reduplicated limbs in
contravention of the complete circle rule

We report here a result which is in contradiction to the 'clock face model' for the regeneration of animal organs. This model^{1,2} is based on the behaviour of insect appendages, imaginal disks and the amphibian limb. It involves treating the organ as a surface on which cells are assigned positional information in terms of a radial and an angular variable. In the case of the amphibian limb, this surface corresponds to the hollow surface of limb dermis and

muscle, so that the 'radial' positional values run from the body to the tip of the digits, while the 'angular' values run around the circumference.

The model comprises two basic rules which determine whether a particular part of an organ will regenerate and which structures will be formed if it does so. The first rule is that of 'shortest intercalation' and states that when tissues of different positional values are brought together then the cells at the edges will proliferate to lay down all the intervening values. In the case of the

Fig. 1 a, Normal axolotl limb. $\times 9.5$; b, Reduplicated limb prepared by an operation on the tailbud embryo. $\times 12$; c, Regenerate formed after amputation of b. $\times 7.5$ (materials and methods as described in ref. 6).

angular variable, the regenerated structures correspond to the shorter of the two possible routes around the clock face. The second rule, and the one with which we are concerned here, is called the 'complete circle rule' and states that regeneration of an appendage in a distal direction (that is, away from the body) cannot take place unless a complete set of circumferential positional values is present at the cut surface. This rule has been used to explain the occurrence, position and orientation of supernumerary limbs in experiments involving the transplantation or rotation of regeneration blastemas in amphibia³.

The most spectacular evidence for the complete circle rule is an experiment performed by Bryant⁴ on double half limbs of newts. These consisted of two posterior or two anterior halves of adult forelimbs fused along the midline. They therefore possessed certain elements in two copies and lacked others altogether. Such double anterior or double posterior limbs were produced surgically, allowed to heal, and then amputated. They either did not regenerate at all, or produced only small cartilage nodules, while control combinations which possessed a complete circle of values regenerated normally.

We have carried out a closely related experiment and obtained a quite different result. We have made a number of double posterior limbs by means of grafts performed on embryos of the

axolotl *Ambystoma mexicanum*. Such limbs can be produced either by grafting a piece of flank tissue to the anterior edge of the forelimb rudiment⁵, or by grafting the central part of the limb rudiment into the flank⁶. Both operations are done at the tailbud stage before the limb bud has appeared. Figure 1(a) shows a normal axolotl forelimb and Fig. 1(b) a double posterior reduplication. Instead of a digital formula I, II, III, IV, this has IV, III, II, III, IV with corresponding elements in the wrist and arm. It lacks digit I, carpal c1, the radiale and the radius. The animals were allowed to develop for about 6 weeks by which time the reduplicated limbs are fully formed. The limbs were then amputated and a study was made of the type of structure which regenerated in their place.

Of 66 reduplicated limbs made in this way, 64 regenerated after amputation (Fig. 1c). Of these 44 gave reduplicated regenerates, not necessarily having the same number of elements as the originals, and 20 gave normal limbs, partial limbs or hybrids between normal and reduplicated limbs. The level of amputation was either the proximal upper arm (49 cases, 47 regenerates of which 30 reduplicated) or the wrist (17 cases, 17 regenerates of which 14 reduplicated). Although the original reduplications did not all contain the same number of elements they all showed a total absence of some of the normally anterior elements and must therefore have had a gap in the sequence of positional values around the circumference whatever the exact manner in which the values are assigned.

This result shows that the complete circle rule does not always apply to the amphibian limb, so whatever the reason for the failure of Bryant's limbs to regenerate, it cannot simply have been their constitution as double half limbs.

We also wish to emphasise that if the clock face model applies to embryonic development as well as to regeneration, as has been claimed³, then reduplicated limbs which lack some elements, and therefore certain of the anterior positional values, should not have been able to develop in the first place. We believe that the occurrence of reduplications in our experiments on amphibian embryos, as well as in the classical literature, can be explained by assuming that a posterior edge arises wherever embryonic limb and flank rudiments are brought into contact⁶, and that it is not necessary to invoke the clock face model to explain such phenomena.

Local perfusion of noradrenaline maintains visual cortical plasticity

We have formed a hypothesis which links two important, but so far separate, research areas, the monoaminergic system discovered by the Swedish group^{1,2} and the phenomenon of critical period plasticity in the visual cortex discovered by Wiesel and Hubel^{3,4}. We propose⁵ that the widespread system of monoaminergic fibres plays a part in regulating plasticity and that, more specifically, catecholamines are responsible for maintaining the high level of plasticity which is observed in the visual cortex during the critical period⁴. In an initial test of this hypothesis, we developed a dose and timing regimen of 6-hydroxydopamine (6-OHDA) to produce significant depletion of catecholamines bilaterally in the visual cortex of developing kittens⁵. The hypothesis was confirmed to the extent that

kittens treated with 6-OHDA do not have the usual cortical plasticity, as measured by a change in the ocular dominance of binocular neurones following monocular occlusion⁵. While all the results we have obtained so far with 6-OHDA are consistent with the view that catecholamines regulate cortical plasticity, other interpretations are possible because of the widespread nature of the changes accompanied by intraventricular 6-OHDA. We now present further evidence in support of the hypothesis from experiments involving microperfusion of catecholamine in localised areas of the visual cortex of animals which would not be expected to show plasticity. These experiments indicate a specific role of noradrenaline (NA) within the cortex because plastic changes are found only in the region of cortex perfused by NA while nearby cortical regions in the same kitten are unaffected.

Table 1 Ocular dominance of single neurones recorded in 11 electrode tracks in the visual cortex of seven monocularly-deprived kittens

Kittens	Ocular dominance group		
	1	2-6	7
Catecholamine-depleted cortex			
R1	4	21	6
R3 (control hemisphere)	5	23	4
R4 (control hemisphere)	11	17	8
R6 (control hemisphere)	4	25	3
*R16	2	24	7
†R5 (track 2)	2	27	5
NA-perfused cortex			
R2	7	5	22
R3 (NA hemisphere)	2	7	25
R4 (NA hemisphere)	2	8	22
R6 (NA hemisphere)	1	7	24
†R5 (track 1)	4	8	16

All kittens (except R16 and R5) had been depleted of brain catecholamine by previous intraventricular 6-OHDA in addition to the monocular deprivation.

*R16 received local perfusion of 6-OHDA (10^{-3}) alone when its right eyelid was sutured.

†R5 was perfused locally with 6-OHDA (10^{-3}) 4 d before the onset of monocular deprivation which coincided with the start of 10^{-3} NA perfusion. Details of R5 protocol are shown in Fig. 1c.

The tracks passed obliquely through the cortex and were placed symmetrically in both hemispheres of R3, R4 and R6. The control tracks in which there are high proportions of binocular neurones showed a number of ocular dominance sequences which indicated that sampling in each track tended to occur across a number of ocular dominance columns. Note that tracks through cortices which had been subjected to catecholamine depletion with local (R5, R16) or intraventricular (R3, R4, R6) 6-OHDA all yield high proportions of binocularly activated neurones (groups 2-6), despite a week of monocular deprivation to which these kittens had been subjected. In contrast, all tracks through catecholamine-depleted cortex which had been locally perfused with NA show a strong bias in favour of neurones activated exclusively by the non-deprived eye (group 7).

Twelve animals were used for this study. Seven kittens aged about 6 weeks had been depleted of cortical catecholamine, five (R1, R2, R3, R4, R6) by intraventricular treatment with 6-OHDA according to a technique already described⁵, and two (R5, R16) by local perfusion of 6-OHDA as described below for NA. A preliminary radiochemical assay⁶ of the catecholamines, dopamine and NA, in such kittens has verified the effectiveness of the intraventricular technique, which produces around 50% depletion of both catecholamines in the visual cortex. Three older animals (two aged 13 weeks, S4 and S8, and one aged 2 years, S1) were also used to test the effects of NA, for, like the 6-OHDA-treated animals, they would not be expected to show much plasticity. One normal 6-week-old kitten (S7) and one normal adult (S6) were tested by 10^{-5} NA perfusion to assess its effects upon the cortex in the absence of visual deprivation.

The right eyelid was sewn shut under ketamine and nitrous oxide anaesthesia in all animals (with the exception of S6 and S7) at the same time as cannulae were placed in the visual cortex. The cannulae were 26-gauge hypodermic needles, and

their tips were placed about 2 mm under the cortical surface with the aid of a micromanipulator and dissecting microscope. Each was cemented into the small hole which had been drilled in the skull for access and each was connected by polyethylene

tubing to an osmotic minipump (Alza) which was filled with the perfusion solution. All solutions contained 0.4% ascorbate (to limit auto-oxidation of NA) in sterile isotonic saline at pH 3. Concentrations of *L*-NA·HCl used varied from

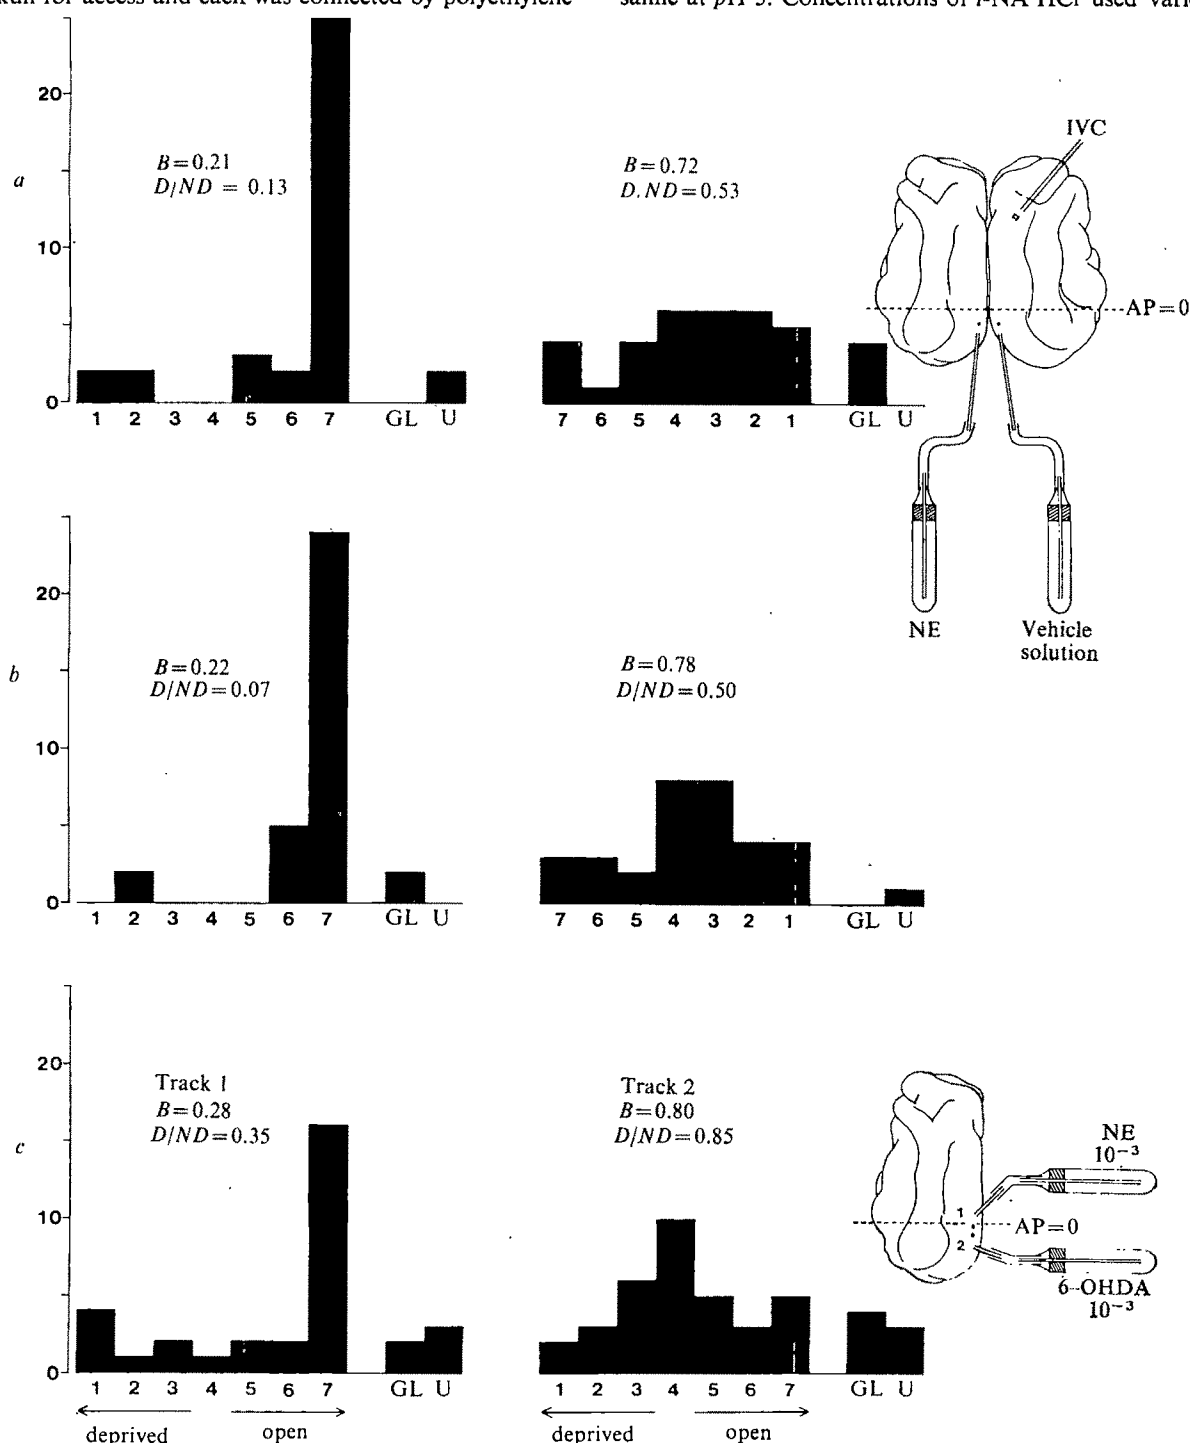

Fig. 1 Ocular dominance histograms compiled from single neurone recordings in the visual cortex of three monocularly-deprived and catecholamine-depleted kittens. They show plastic changes in regions perfused with NA (left-hand side, 10^{-4} and 10^{-5} , respectively in *a* and *b*) but not in regions perfused with the acidic vehicle solution alone (right-hand side). Ocular dominance groupings are based on the criteria of Hubel and Wiesel¹⁰. GL and U refer to lateral geniculate fibres and unresponsive units, respectively. *B* (Binocularity) is defined as the ratio of group 2-6 cells to the total number of visually responsive cells. *D/ND* (Deprived/Non-deprived) is the ratio of the number of cells dominated by the deprived eye to the number dominated by the non-deprived eye, excluding group 4 cells. Values of this index < 1 indicate a shift toward the open eye. In the diagram on the right, IVC indicates the position of the intraventricular cannula used for previous administration of 6-hydroxydopamine (6-OHDA). *a* and *b*: both kittens (R3 and R6, respectively) were treated with 6-OHDA during the sixth week to bring about bilateral catecholamine depletion according to the dose regimen reported previously³. During the seventh week (age 46 d, *a*; 48 d, *b*), right eyelid suture was performed simultaneously with the insertion of minipump/cannula combinations containing NA and vehicle solution (left hemisphere) and vehicle solution alone (right hemisphere). Seven days later, the minipump/cannula combinations were removed and single neurone recording was carried out in each hemisphere close to the site of cannulation. Note that a change of binocularity to favour the non-deprived eye occurs in cortical regions reached by NA but not in the region depleted of catecholamine and locally perfused by acidic vehicle solution alone. *c* (R5): catecholamine depletion was produced locally by microperfusion of 6-OHDA (10^{-3} concentration) from a minipump/cannula combination which was placed at the age of 48 d. Four days later, a second minipump/cannula was placed, containing 10^{-4} NA and simultaneously the right eye was closed. A further 7 d later (at the age of 60 d), single unit recording was carried out from two electrode tracks with their entry points separated by 2 mm. Only the electrode track passing through the NA-perfused region shows an ocular dominance shift. Data from an additional four kittens confirm these results and are shown in Table 1.

5×10^{-3} ($5 \mu\text{g } \mu\text{l}^{-1}$) to 10^{-5} ($10 \text{ ng } \mu\text{l}^{-1}$) in different animals. In most animals a control cannula containing the acidic vehicle solution was placed in the right visual cortex in addition to the cannula for perfusion of NA in the left visual cortex. In two cases (R5, Fig. 1c and R16) a minipump/cannula was filled with 10^{-3} 6-OHDA in the vehicle solution and placed 4 d in advance of right eye closure and the placement of a second minipump/cannula which contained either 10^{-3} NA (R5) or the vehicle solution alone (R16). After the pumps had been wetted by placement in the subcutaneous tissue of the neck, they delivered their contents at approximately $1 \mu\text{l h}^{-1}$ for one week, by which time they were empty (total capacity, $170 \mu\text{l}$). The duration of lid closure was also confined to one week synchronous with NA perfusion, at the end of which each animal was prepared for single unit recording by standard techniques⁷. Recordings were carried out in cortical area 17 with tungsten-in-glass microelectrodes⁸. Long penetrations (3–6 mm) were made by passing obliquely (5° medial and 5° anterior) down the medial bank of the postlateral gyrus to maximise the number of laminar and ocular dominance boundaries which were crossed. Symmetrical penetrations were usually made in both hemispheres. For each neurone encountered, receptive field characteristics were determined, and each was assigned to one of seven ocular dominance groups according to the criteria of Hubel and Wiesel⁹. Electrode tracks were reconstructed histologically. Sections were stained both with cresyl violet to show Nissl substance and with a silver stain for fibres. These sections showed that microelectrode tracks could pass through histologically normal cortex as close as 1 mm from the cannula tip.

As previously described, penetrations through the cortex of the 6-OHDA-treated kittens revealed a high proportion of binocular neurones despite the week-long monocular deprivation which normally produces a complete ocular dominance shift in kittens of this age. This was also true for control penetrations through regions of catecholamine-depleted cortex which had been perfused with the acidic vehicle solution alone.

Fig. 2 Effect of NA perfusion in the visual cortex of cats which had not been subjected to previous catecholamine depletion. Conventions as in Fig. 1. Open arrow indicates open eye during period of monocular deprivation. *a*, Decreased binocularity following one week of monocular deprivation in three older cats (S1, 2 yr; S4 and S8, 13 wk). The histogram is based upon data from three electrode tracks, one from the NA-perfused hemisphere of each cat. Each electrode track yielded comparable numbers of neurones and the same ocular dominance profile. Binocularity in the three cats was respectively, S1, 30%; S4, 33%; S8, 24%. *b*, Normal binocularity obtained from one long electrode penetration in the control hemisphere (not perfused with NA) of each of the monocularly deprived cats S4 (30 neurones) and S8 (29 neurones), which showed reduced binocularity in their NA-perfused hemispheres (*a*). As expected on the basis of their age, there are no obvious changes in ocular dominance following one week's eye occlusion. *c*, Relatively normal ocular dominance shown by two cats (S7, 6 weeks; S6, > 1 yr) in which the visual cortex had been perfused with NA (10^{-3}) for one week, during which time they had normal binocular experience. The histograms from both animals were closely similar and each had the slight reduction of neurones driven by the ipsilateral eye which appears in the combined histogram.

Such penetrations were remarkable for their normality with respect to all receptive field properties of the single neurones encountered, including binocularity, which showed a normal distribution unaffected by the monocular deprivation (Fig. 1a, b; Table 1). These penetrations also confirm that our tracks adequately sampled across ocular dominance regions.

In striking contrast to the control tracks, those through cortical regions perfused with NA yielded few binocular neurones, and the ocular dominance distribution was markedly skewed in favour of the non-deprived eye (Fig. 1a, b; Table 1). All of these neurones, except for their ocular dominance bias, also appeared normal in their responsiveness and in their selectivity for stimulus attributes like orientation and direction of movement. This effect was consistent throughout all 6-OHDA-treated kittens locally perfused with NA, at concentrations from 5×10^{-3} down to 10^{-5} NA.

The presence of both normal and shifted ocular dominance distributions in different hemispheres of the same kitten provides a control for possible nonspecific effects of catecholamine depletion following 6-OHDA treatment. A localised effect is further suggested by results of the experiment illustrated in Fig. 1c, where catecholamine-depleted and catecholamine-rich cortical regions were examined side by side in the same hemisphere. The catecholamine-depleted region, treated with local 6-OHDA 4 d before the onset of monocular occlusion and NA perfusion, shows normal binocularity, while the NA-perfused cortex, only 2 mm away, shows a clear-cut ocular dominance shift.

In addition to the apparent restoration of plasticity in catecholamine-depleted kittens, NA apparently restored some degree of plasticity to the three normal, older animals. The NA-perfused cortex of all three animals yielded similar ocular dominance histograms, which showed a significant reduction in binocularity following a week-long monocular closure (Fig. 2a). These changes were restricted to the NA-perfused cortical hemisphere and were in marked contrast to the normal distributions obtained in the opposite hemisphere (Fig. 2b). No reduction in binocularity was observed in the cortex of a normal kitten and a normal adult perfused with NA (Fig. 2c), so this effect can be attributed to the abnormal visual experience with NA playing a permissive role. The change in ocular dominance seems to be particularly significant as it was produced by only one week's monocular deprivation in animals outside of the accepted limits of the critical period.

These findings therefore strengthen our hypothesis that catecholamines play a part in the regulation of critical period plasticity. We do not yet know the effects on cortical plasticity of local perfusion of other monoamines, such as dopamine and serotonin, nor do we know the type of receptor involved, although the current paradigm lends itself quite readily to answering such questions.

Connectivity changes in a class of motoneurone during the development of a nematode

THE ventral nerve cord of the nematode *Caenorhabditis elegans* contains a linear array of motoneurons (Fig. 1) which innervate the body muscles that mediate locomotion. The adult ventral cord has about three times as many cells as that of the first stage larva. The development events that generate the adult complement of cells occur in a period preceding the first larval moult. During this period we find that a class of pre-existing, juvenile motoneurons changes its pattern of connectivity. Neuromuscular junctions are removed from ventral muscles and are reformed onto dorsal muscles. Similarly the dendritic input to these neurons changes over from the dorsal to the ventral side.

The structure and connectivity of ventral cord motoneurons in adult hermaphrodites has been determined by serial section reconstructions of electron micrographs¹. The salient features of the structure are summarised below:

Motoneurons in the ventral cord can be categorised into five distinct morphological classes designated A, B, C, AS and D (Fig. 2). Classes A, B and D can be subdivided into those members that innervate ventral muscles (VA, VB and VD) and those that innervate dorsal muscles (DA, DB and DD). The members of a class are evenly distributed along the length of the cord such that all body muscles receive innervation from at least one member from each class. All motoneurons, except those in class D, receive their synaptic input from interneurons which have processes that run along the length of the ventral cord. Class D neurons, on the other hand, receive their innervation from the other classes of motoneurons. In the adult each DD motoneurone has a process which runs on the ventral side where it receives synaptic input from classes VA, VB and C motoneurons (Fig. 2). These connections are often made onto small dendritic spines which intercept neuromuscular junctions (Fig. 3a). The cell body is situated near the posterior end of the process and a branch comes off the anterior end. This branch leaves the ventral cord and runs round to the dorsal cord as a circumferential commissure. When it enters the dorsal cord it splits and runs both anteriorly and posteriorly, the posterior branch being longer. Many neuromuscular junctions (NMJs) are formed on this dorsal process (Fig. 3b) little, if any, synaptic input being received on it from the other neurone classes. The extent of both the dorsal and ventral cord processes is limited, each generally ending abruptly in a gap junction to the process of a neighbouring DD neurone. Thus the DD neurons receive their synaptic input from motoneurons

in a well defined region on the ventral side and synapse onto muscles in the same region on the dorsal side. The VD neurons have a similar shape to the DD neurons although their processes are shorter (Fig. 2). These neurons are the converse of DD neurons, receiving their innervation from motoneurons on the dorsal side and forming NMJs on the ventral side.

When the first stage larva hatches there are a total of 22 motoneurons in the ventral cord and associated ganglia. This number increases to 76 in a period of post-embryonic development that commences about 9 h before the first larval moult^{2,3}. It was found that all the VA, VB, C, AS and

Fig. 2 Classes of motoneurone in the ventral cord. All the motoneurons of the ventral cord have a simple well defined shape. Neuromuscular junctions (▲▲▲) are made 'en passant' along the length of a process. Similarly synaptic input occurs along other processes (↑↑↑). Muscle cells send out arms to the region of the cord where the motor neurone axons reside. All motoneurons which innervate the body muscles have cell bodies (●) which are situated in the ventral cord. Each motoneurone which innervates dorsal muscles sends out a commissure which leaves the ventral cord and runs circumferentially around the animal to the dorsal side. When these processes reach the dorsal midline they turn and together make up the dorsal nerve cord. There are five distinct classes of motoneurone in the ventral cord, A, B, C, AS and D, three of which are shown. Each class has a unique pattern of synaptic input¹. Some classes are only present in adults (A), others are present in both juveniles and adult animals (J and A). Neurones in class A have axons that project anteriorly, whereas those in class B have axons that project posteriorly. Both these classes can be subdivided into neurones that innervate ventral muscles and those that innervate dorsal muscles. Class D also has both dorsal and ventral members. Neurones in this class do not receive any synaptic input from interneurons but rather from other classes of motoneurons. Ventral class D neurones receive synaptic inputs from class A, B and AS neurones on the dorsal side and innervate ventral muscles. Dorsal class D neurones in the adult (A) innervate dorsal muscles and receive their synaptic input from class A, B and C neurones on the ventral side. In the juvenile (J) they innervate ventral muscles and receive their synaptic input from DA and DB neurones on the dorsal side. Both the dorsal and ventral processes of the type D neurones end abruptly in gap junctions to the processes of neighbouring class D neurones.

Fig. 1 Cell bodies in the ventral cords of first and second stage larvae. The number of motoneurons in the ventral cord increases in a period of post-embryonic development that commences about 9 h before the first larval moult. *a*, A first stage larva before this period has started; *b*, a second stage larva that has completed all its ventral cord cell divisions. Animals were fixed in Carnoy's and stained with the fluorescent nuclear stain Hoechst 33258. Scale bars, 100 μ m.

Fig. 3 Interneurons which come from the nerve ring send processes which run alongside a hypodermal ridge (H) which underlies the cuticle (CU). These interneurons synapse onto class A, B and AS motoneurons. The body muscles (M) send out arms (MA) which go to the endplate region of the motoneurone to receive their synaptic input. *a*, A VA motoneurone in the ventral cord of an adult hermaphrodite synapsing onto some muscle arms, the synapse being intercepted by the dendritic spine of a dorsal type D neurone (DD). *b*, The same DD neurone synapsing onto muscle arms in the dorsal cord (the view has been rotated 180°). There are far fewer processes in the dorsal cord as all the interneurons run in the ventral cord. *c*, A DD neurone synapsing onto muscle arms in the ventral cord of a first stage (L1) larva. This provides the sole synaptic input for the ventral side in the L1 stage yet these synapses disappear completely by the second (L2) stage. *d*, The same DD cell receiving its synaptic input on the dorsal side from a DA motoneurone. There are two classes of motoneurone which synapse onto dorsal muscles and DD cells at this stage, dorsal type A (DA) and dorsal type B (DB). Scale bars, 1 μ m.

VD neurones present in the adult are generated in this period². We deduced by subtracting these neurones from the total adult complement that juveniles must have only DA, DB and DD motoneurons in their ventral cords. This seemed paradoxical as the lack of motoneurons on the ventral side would imply that neither the ventral muscles nor the DD neurones receive any innervation.

To resolve this paradox two first stage larvae each about 10 h old were fixed, sectioned and reconstructed as described in ref. 4. Motoneurons in the juvenile cord could be unambiguously related to their counterparts in adults because of the low level of variability in the sequences of cell types along the cord^{1,2}. Cells which are DA and DB neurones in the adult were found to be the same in the larvae. This was not the case with the DD neurones, however; the morphology of the processes was the same but the

Table 1 Disposition of neuromuscular junctions in *C. elegans* larvae

		Dorsal NMJs	Ventral NMJs
First stage larva <i>a</i>	DD 1	0	20
First stage larva <i>b</i>	DD 1	0	14
	DD 2	0	15
	DD 3	0	9
Adult	DD 1	31	0
	DD 2	28	0
	DD 3	20	0

Two first stage larvae were reconstructed, *a* and *b*. The first reconstruction (*a*) covered the first DD motoneurone, the second (*b*) was longer and covered the first three DD neurones in the anterior ventral and dorsal nerve cords. The number and location of NMJs formed by these neurones is shown and compared with their counterparts in a reconstructed adult.

Fig. 4 *a*, The dorsal cord of a fourth stage larva of the mutant *el466*. This mutant is defective in post-embryonic development and none of the late developing motoneurones are formed. The DD neurone is synapsing onto muscles on the dorsal side with no synapses on the ventral side as in wild-type adult animals. Some of the original synaptic input to the DD neurones (that is, from the other motoneurone classes on the dorsal side) seems to persist (*b*), a feature which is seen rarely in wild-type adults. Scale bars 1 μ m.

disposition of the synapses was different (Table 1). In juveniles DD neurones had neuromuscular junctions on their ventral processes (Figs 2 and 3c) whilst their dorsal processes received synaptic input from DA and DB motoneurones (Fig. 3d) resembling the VD neurones of adults. Thus during the course of post-embryonic development all the ventral NMJ's from the DD cells disappear and new NMJ's are formed on the dorsal side. Similarly the synaptic input changes from the DA and DB neurones on the dorsal side to inputs from the newly formed VA, VB and C motoneurones on the ventral side. A late second stage larva has also been partially reconstructed and the DD neurones of this animal were found to be the same as those of the adult. It seems likely that the change in the connectivity of the DD motoneurones takes place between the first and second larval stages at the same time as the late developing motoneurones are formed^{2,3}.

Mutants have been isolated which are defective in various aspects of post-embryonic development (H. R. Horvitz, and J. E. Sulston, unpublished). In one of these mutants, *lin-6 1* (*el466*) none of the late-developing motoneurones are produced. The ventral cord was reconstructed in a fourth stage larva of this mutant and we found that the DD motoneurones formed NMJs on the dorsal side (Fig. 4a) as they do in wild-life adult animals. The DD neurones of the mutant received no synaptic input on the ventral side because the late developing motoneurones which provide all the synaptic input in wild-type adults were absent. It therefore seems likely that the DD motoneurones displace their NMJs from the ventral to the dorsal side in this mutant as they do in wild-type animals leaving the ventral muscles with no synaptic input. This is consistent with the observation that the first stage larvae of this mutant have apparently normal locomotory behaviour, whereas all the later stages are uncoordinated in their body movements (J. E. Sulston, personal communication). There are some indications the DD neurones of the mutant continue to receive some synaptic input from DA and DB neurones on the dorsal side (Fig. 4b) unlike wild-type adults that rarely have such connections¹. The observations that the DD neurones in *el466* change those sites where NMJs are formed in the same way as those in wild-type animals suggest that this

process is independent of the formation of NMJs from the late developing neurones. This may not be the case for the sites of synaptic input for the DD neurones since some of the juvenile sites seem to persist in this mutant.

Connectivity changes in normal⁴ and abnormal development⁵ have been described in other organisms. The behaviour of the DD neurones in *C. elegans* provides a rather extreme example of neuronal plasticity during development where not only are connections altered but also the direction of information flow in processes is reversed.

We thank Nicol Thomson for technical assistance and Sydney Brenner, Bob Horvitz and John Sulston for helpful discussions.

Dopamine receptors localised on cerebral cortical afferents to rat corpus striatum

STRIATAL dopamine receptors, monitored by dopamine-sensitive adenylate cyclase activity^{1,2} or binding of ³H-haloperidol³⁻⁵ apparently represent distinct entities because of differences in drug sensitivity and the pattern of their ontogenetic development^{6,7}. Dopamine also elicits both excitatory and inhibitory effects on striatal neurones^{8,9}. We have examined the effects of selective degeneration of striatal intrinsic neurones with the neurotoxin, kainic acid^{10,12}, and elimination of cortico-striate afferents by cortical ablation¹¹ on the dopamine receptors in rat striatum.

We present evidence that a substantial portion of striatal ^3H -haloperidol receptor sites are localised to axons of cerebral cortical afferents whereas dopamine-sensitive adenylate cyclase is confined to neurones intrinsic to the striatum.

After anaesthesia with Equi-thesin (0.6 ml, Jensen-Salisbury), Sprague Dawley rats (160 g) were positioned in a David Kopf small animal stereotaxic apparatus and a 0.3-mm Hamilton cannula, was inserted into the striatum through a burr hole in the calvarium (coordinates: 7.9 A; 2.6 L; 4.8 V). Kainic acid (Sigma) 2 μg in 1 μl of artificial cerebrospinal fluid titrated to pH 7.4, was infused and the scalp was then apposed with sutures. For unilateral cortical ablations, the calvarium overlying the parietal and frontal cortex was removed and the underlying cortex was removed to the level of the corpus callosum by aspiration or by shallow knife cuts; bleeding was controlled with gel foam. The rats received a prophylactic intraperitoneal injection of ampicillin. Ten days after a striatal kainate injection, the cortex on the lesioned side was ablated for the studies of additivity. At various times after kainic acid injection or 5 d after cortical ablation, the rats were decapitated and the corpus striatum ipsilateral to the lesion, the contralateral unlesioned striatum and striata from unlesioned animals were assayed for ^3H -haloperidol binding³, dopamine-sensitive adenylate cyclase, glutamic acid decarboxylase, choline acetyltransferase and tyrosine hydroxylase as previously described¹².

Twenty-four hours after striatal kainate injections, ^3H -haloperidol binding and dopamine-sensitive adenylate cyclase were not significantly different from control values; however, by 2 d after injection, dopamine-sensitive adenylate cyclase was reduced by 85% compared with contralateral and control values whereas ^3H -haloperidol binding was reduced by only 20% (Fig. 1a). The 85% decline in dopamine-sensitive adenylate cyclase was maintained for at least 22 d after kainate lesion and was associated with a similar reduction in this cyclase in the ipsilateral substantia nigra, an area innervated by striatal neurones¹⁴. ^3H -haloperidol binding fell to 60% of control levels with a maximal reduction at 6 d and no further change apparent 22 d after kainate lesion. The kinetics of ^3H -haloperidol binding were determined by Scatchard analysis (Fig. 1b). The dissociation constant for ^3H -haloperidol, 0.9 nM, was the same in control and lesioned striata; however, the maximum number of binding sites was reduced by 40% in the kainate-treated striatum. As previously reported¹², at 22 d after striatal kainate lesion, tyrosine hydroxylase activity was not significantly different from control but there was a

Fig. 1 a, Time course of loss of striatal dopamine-stimulated adenylate cyclase activity (○) and ^3H -haloperidol receptor binding (●) after unilateral striatal kainate injection. Adenylate cyclase activity was stimulated by 50 μM dopamine with basal levels measured in the presence of 5 μM fluphenazine; ^3H -haloperidol binding was assayed with 0.8 nM ^3H -haloperidol in the presence of absence of 0.1 mM dopamine. b, Scatchard analysis of striatal ^3H -haloperidol binding 22 d after unilateral kainate injection. Binding was measured at five concentrations of ^3H -haloperidol (0.5–8.0 nM) in the presence and absence of 0.1 mM dopamine in the lesioned (●) and contralateral control striata (○) pooled from five rats. The experiment was repeated three times and the Scatchard plots drawn from the mean data. For lesioned striata, $K_D = 0.89$ nM and B_{max} (maximum binding) = 20.4 pmol per g wet weight. In control striata, $K_D = 0.90$ nM, $B_{max} = 32.5$ pmol per g wet weight.

60% reduction in the activities of choline acetyltransferase and glutamic acid decarboxylase, enzymatic markers for the cholinergic and GABAergic neurones intrinsic to the striatum (Table 1). Thus, kainate-induced changes in dopamine-sensitive adenylate cyclase and ^3H -haloperidol binding differ both in extent and in time course.

The fact that 60% of the haloperidol binding sites remain intact after ablation of the intrinsic neurones of the striatum by kainic acid suggests that some of these sites are localised on intrastriatal axons of neurones with cell bodies lying outside the striatum. To investigate this possibility, we evaluated the effects of cortical ablation, which destroys a major projection to the striatum¹⁵. The activity of tyrosine hydroxylase, an enzyme localised to dopaminergic terminals in the striatum was used as an index of nonspecific damage after the cortical lesion; only striata in which the activity of tyrosine hydroxylase was at least 85% of control striata were used for computation of ^3H -haloperidol binding. In decorticate rats, the specific striatal binding of ^3H -haloperidol decreased by 35% (Table 1). Scatchard analysis of the kinetics of binding indicates that the reduction reflects

Table 1 Effect of kainic acid lesion and cortical ablation on rat striatal enzyme activity and ^3H -haloperidol binding

	^3H -Haloperidol binding (% control \pm s.e.m.)	Tyrosine hydroxylase activity	Choline acetyltransferase activity	Glutamic Acid decarboxylase activity
Kainate 22 d post-lesion	64 \pm 3* (6)	97 \pm 6 (6)	49 \pm 4† (6)	42 \pm 7‡ (6)
Cortical ablation 5 d post-lesion	68 \pm 5† (22)	101 \pm 3 (22)	73 \pm 5† (16)	99 \pm 7 (12)
Kainate and cortical ablation	30 \pm 5† (9)	120 \pm 9 (9)	39 \pm 6† (9)	41 \pm 6† (8)

Rats received an intrastriatal injection of kainic acid (2 μg) or cortical ablation or kainate injection followed by cortical ablation as described in the text. The striata were assayed for the activities of tyrosine hydroxylase, choline acetyltransferase and glutamate decarboxylase¹⁰ and specific binding of ^3H -haloperidol³. Results are presented as % (\pm s.e.m.) of the level in the contralateral nonlesioned striata which did not differ significantly from those in unlesioned rats. Absolute values for the contralateral striatum expressed in terms of mg tissue: ^3H haloperidol binding 0.15 fmol (710 c.p.m. per sample) tyrosine hydroxylase, 230 pmol h^{-1} ; choline acetyltransferase, 20 nmol h^{-1} ; glutamic acid decarboxylase 13 nmol h^{-1} . The number of separate preparations is indicated in parentheses.

* $P < 0.005$.

† $P < 0.001$.

‡From ref. 13.

a loss of receptor sites with no alteration in affinity for the ligand. In contrast, the dopamine stimulated formation of cyclic AMP in striatal homogenates was not significantly altered by decortication (lesioned 10.5 ± 1.5 pmol $\text{mg}^{-1} \text{min}^{-1}$, control 12.5 ± 1.0 pmol $\text{mg}^{-1} \text{min}^{-1}$; $N = 9$). Basal cyclase (16.0 ± 2.0 pmol $\text{mg}^{-1} \text{min}^{-1}$) in the decorticate striata was reduced by 37% as compared to control. The activities of tyrosine hydroxylase and glutamic acid decarboxylase were not altered by decortication but a modest but consistent 27% ($P < 0.001$) reduction in choline acetyltransferase activity is observed. Less extensive cortical lesions do not reduce striatal choline acetyltransferase^{15,16}.

In rats in which striatal kainate injection was followed by ablation of the overlying cerebral cortex, the specific binding of ³H-haloperidol decreased by 70%, indicating additive effects of the two lesions (Table 1). The activities of choline acetyltransferase and glutamic acid decarboxylase in the combined lesioned striatum were not significantly different from those in striata after kainate injection alone. Histological examination of Nissl-stained sections of striata following kainic acid lesions revealed a near complete loss of neuronal cell bodies, a gliotic reaction and intact internal capsule fibres in agreement with detailed histological studies of the lesion¹⁷. After cortical ablation, the intrinsic neurones appear normal but a gliotic reaction limited to the internal capsule fibres is evident.

These observations indicate a clear dissociation between the activity of dopamine-sensitive adenylate cyclase and ³H-haloperidol binding sites in the striatum. The nearly complete loss of the dopamine-sensitive adenylate cyclase following striatal kainate lesion indicates that it is largely confined to neurones intrinsic to the striatum and their nigral projections while the persistence of 65% of the ³H-haloperidol binding in the same striatum suggests that a majority of the binding sites are contained on other tissue elements. The additional depletion of ³H-haloperidol binding after cortical ablation favours its localisation to axons or terminals of the cerebral cortical neuronal input to the striatum. Most pharmacological effects of neuroleptics correlate better with affinity for ³H-haloperidol binding sites than with effects on the dopamine-sensitive cyclase⁸, suggesting that the dopamine receptors localised to cortical afferents may represent a major site of pharmacological action of the drugs.

Coenzyme A is a purine nucleotide modulator of acetylcholine output

FUNCTIONAL roles have been proposed for the purine nucleotides and nucleosides shown to be released by several neural tissues^{1,2}. In the autonomic nervous system, ATP or a related purine compound has been ascribed a transmitter role in the 'purinergic' nerve hypothesis³. Although some metabolites of ATP have been demonstrated in perfusates of field-stimulated gastrointestinal smooth-muscle preparations⁴, the precise identity of the mediator released from 'purinergic' nerves has not been established, and the existence of such nerves is not widely accepted⁵. Structure-activity considerations suggested to us that coenzyme A (CoA), a substituted purine nucleotide, should interact with the 'purinergic' receptor—to our knowledge there are no reports of such interactions, or of any other autonomic effect of CoA, in the literature. We report here the pre-synaptic inhibitory effects of CoA and its analogues on acetylcholine release.

The effects of CoA and its analogues (acetyl-CoA, adenosine 3'5'-diphosphate (adenosine 3'5' diPO₄)) on the mechanical activity of electrically-stimulated guinea-pig ileum⁶ were compared with those of the nucleotides ATP, 3'5'-cyclic AMP, dibutyl-3'5'-cyclic AMP (dbcAMP) and to noradrenaline, pantothenic acid and β -mercaptoethylamine. CoA (4.0×10^{-7} – 5.0×10^{-6} M), acetyl-CoA (4.0×10^{-7} – 4.6×10^{-6} M), adenosine 3'5' diPO₄ (4.0×10^{-7} – 1.6×10^{-6} M) and ATP (4.0×10^{-7} – 2.5×10^{-6} M) produced concentration-dependent reductions of the response of the ileum (Fig. 1) without changing the sensitivity of the preparation to exogenous acetylcholine (ACh).

Figure 2 shows the relative potencies of these compounds, adenosine 3'5' diPO₄ being the most potent. Pantothenic acid and β -mercaptoethylamine (substituents in the side chain of CoA) were inactive at concentrations as high as 1×10^{-4} M. The inhibitory effects of CoA and its analogues depended on the frequency of stimulation, contractions induced by high frequency (5 and 10 Hz) being reduced by approximately 32% at concentrations (5×10^{-8} – 1×10^{-5} M) which produced a 100% inhibition at 0.2 and 1 Hz. Intact adrenergic mechanisms were not necessary for the inhibition; it was not altered by treatment with either phentolamine (5×10^{-6} M) plus propranolol (1×10^{-6} M) or guanethidine (1×10^{-5} M).

Theophylline, a blocker of adenosine receptors⁷⁻⁹, produced a concentration-dependent enhancement of the responses to stimulation of Auerbach's plexus. The responses were enhanced by theophylline (2.5×10^{-3} – 1×10^{-4} M), this being more pronounced at low frequencies of stimulation (0.2–1 Hz) than at high (5–10 Hz). Parallel displacements to the right by theophylline of the log concentration-response curves of CoA, acetyl-CoA, adenosine 3'5' diPO₄ and ATP (Fig. 2 a–d; P for slopes > 0.05) suggested competitive antagonism. Analysis of this antagonism by the method of Arunlakshana and Schild¹⁰ yielded linear isoboles, the slopes of which were not significantly different from unity ($P > 0.05$, Fig. 2 e–h). In addition, the apparent pA_2 values (derived from Fig. 2) were similar, indicating that these agonists and the antagonist all act at the same receptor. Antagonism by theophylline is not mediated through elevation of intracellular cyclic AMP because neither cyclic AMP (5×10^{-7} – 5×10^{-6} M) nor the dibutyl derivative (1×10^{-6} – 1×10^{-5} M) added exogenously altered the effects of CoA or the other purine nucleotide agonists.

Dipyridamole, a compound which potentiates the effects of adenosine¹¹⁻¹⁴, in concentrations up to 9.9×10^{-7} M reduced the height of the contractions of the ileum without influencing the sensitivity to added ACh (Fig. 3). Dipy-

ridamole also potentiated the inhibitory effects of CoA, adenosine 3'5'-diPO₄, and ATP, producing 48-, 34- and 49-fold decreases in the EC₅₀ values respectively (see Fig. 3). Theophylline (2.5×10^{-5} – 1×10^{-4} M) prevented the effects of dipyrindamole on the responses of the muscle strip both to stimulation at 0.2 Hz and to CoA and the other purine nucleotides.

The effects of CoA and the other purine nucleotide agonists were also studied on the resting and stimulated release of ACh from Auerbach's plexus as assayed on isolated guinea-pig ileum by the method of Paton and Vizi⁶. At concentrations of 2×10^{-6} M, these compounds significantly ($P < 0.05$) reduced the resting and stimulated (0.2 Hz) release of ACh (Table 1). The effects of these compounds were concentration-dependent, maximal inhibi-

Fig. 1 Responses of electrically stimulated guinea-pig ileum to purine nucleotide agonists in the absence (a) and presence (b) of theophylline. Agonists were added at arrows. Longitudinal muscle strips from male guinea pigs (250–400 g) were prepared according to the method of Paton and Vizi⁶ and set up in 10-ml organ baths containing Krebs's solution (composition, in μ M: KCl 4.75; CaCl₂ 2.54; KH₂PO₄ 1.19; NaCl 118; NaHCO₃ 25; and glucose 11.0) and bubbled with 95% CO₂. Temperature was maintained at 37 °C and the pH at 7.3. Longitudinal contractions were recorded auxotonically with a Harvard Apparatus smooth muscle transducer using an applied load of 1 g. Field stimulation⁶ was achieved by means of trains of supramaximal rectangular pulses of 1 ms duration applied through platinum electrodes at the top and bottom of the bath. Frequency of stimulation was 0.2 Hz. Concentrations of agonists used were: coenzyme A (CoA) 3.0×10^{-6} M, acetyl-coenzyme A (AcCoA) 3.0×10^{-6} M, adenosine 3'5' diphosphate (3'5' diPO₄) 9.5×10^{-7} M, and ATP 1.7×10^{-6} M. Tissues were exposed to theophylline (5×10^{-5} M) for 30–45 min before addition of agonists in all experiments.

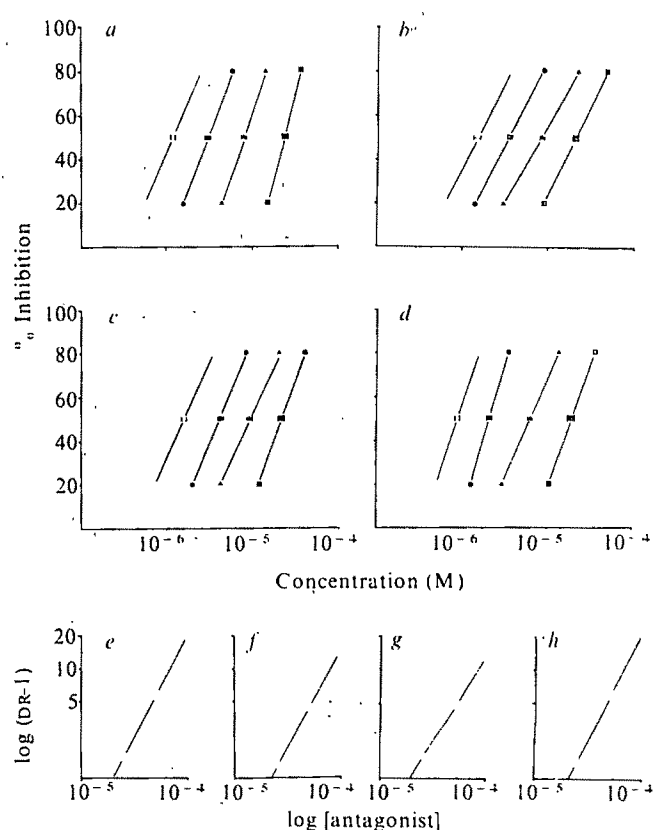

Fig. 2 a–d, Log concentration–response curves for the purine nucleotide agonists on electrically stimulated guinea pig ileum in the absence and presence of theophylline. Responses to ATP (a), CoA (b), AcCoA (c) and 3'5' diPO₄ (d) are shown in the absence (○) and presence of theophylline, 2.5×10^{-5} M (●), 5×10^{-5} M (▲) and 1×10^{-4} M (■). Responses were calculated as percentages of maximum inhibition. Concentration of agonists yielding 50% of maximum response (EC₅₀) are ATP: 1.2×10^{-6} M, CoA: 1.5×10^{-6} M, AcCoA: 1.6×10^{-6} M, and 3'5' diPO₄: 8.8×10^{-7} M. Regression lines constructed from pooled results of three to five experiments, were calculated using the least squares method and ranges of the 95% confidence intervals (bars at EC₅₀) obtained by the method of Wonnacott and Wonnacott²². e–h, Schild¹⁰ plots showing competitive nature of the antagonism between theophylline and the purine nucleotide agonists. Plots of log dose ratio – 1 (DR – 1) against log concentration of theophylline yielded apparent pA_2 values of 4.70 for ATP (a), 4.68 for CoA (b), 4.74 for AcCoA (c) and 4.67 for 3'5' diPO₄ (d). Values for slopes were not significantly different from 1 ($P > 0.05$).

tion being obtained, at concentrations of 1 to 8×10^{-5} M. No tachyphylaxis was observed. Theophylline 10^{-4} M markedly enhanced the release of ACh both at rest and following stimulation ($P < 0.05$). The inhibitory effects of CoA and its analogues, as well as of ATP, on ACh release were antagonised by theophylline (Table 1).

CoA and its analogues are thus able to reduce the release of ACh from Auerbach's plexus and theophylline competitively antagonises these inhibitory effects. The observation that theophylline enhanced both the mechanical activity and the release of ACh poses the question of whether endogenous CoA and/or its derivatives might control the release of ACh. If so, it is possible that the amount of ACh measured represents an already reduced output. This could explain why the output of ACh per stimulus is very low when a high frequency of stimulation is applied¹⁸, a situation in which greater amounts of CoA might be released to act as a purine nucleotide brake on ACh output. This same role might be invoked for the observed effects of ATP.

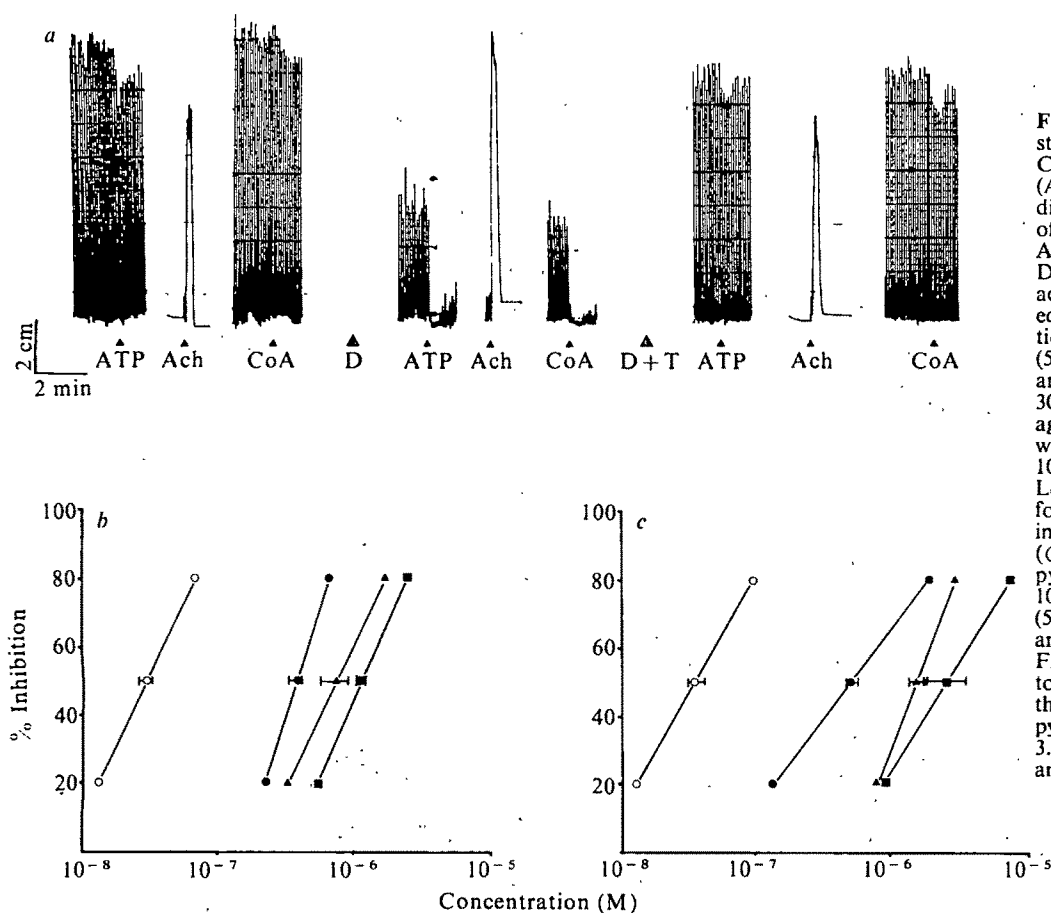

Fig. 3 *a*, Responses of electrically stimulated guinea pig ileum to CoA, ATP, and acetylcholine (ACh) alone, in the presence of dipyrindamole, and in the presence of dipyrindamole plus theophylline. Agonists were added at arrows. Dipyrindamole (9.9×10^{-7} M, D) was added at the arrow and allowed to equilibrate for 30 min before addition of agonists. Theophylline (5.0×10^{-3} M, T) was added at arrow and allowed to equilibrate for 30–45 min before addition of agonists. Agonist concentrations were CoA: 2.0×10^{-7} M, ATP 2.0×10^{-7} M and ACh 5.0×10^{-8} M. *b*, *c*, Log concentration–response curves for ATP (*b*) and CoA (*c*) alone (■) in the presence of dipyrindamole (○), and in the presence of dipyrindamole + theophylline 2.5×10^{-5} M (●) or dipyrindamole + Theo (5×10^{-5} M) (▲). Regression lines and ranges were calculated as for Fig. 2 using pooled data from three to five experiments. EC_{50} values in the absence and presence of dipyrindamole are 1.5×10^{-6} M and 3.5×10^{-6} M respectively for CoA and 1.4×10^{-6} M and 2.9×10^{-6} M respectively for ATP.

Neurally-released ATP has been detected using the firefly luciferase luminescence technique¹⁸ or has been inferred from chromatographic detection of degradation products such as inosine and hypoxanthine⁴. The neural origin of such ATP is not in question, but the exact nerves involved are³. A 'purinergic' nerve, synthesising and releasing ATP as the putative neurotransmitter, has been proposed³. Our evidence of enhanced ACh output after theophylline as well as the ability of dipyrindamole to attenuate the mechanical response, supports the notion of an endogenously-released purine-like compound which acts presynaptically to reduce ACh output from cholinergic nerve terminals. We have shown that exogenous ATP as well as CoA and its analogues do indeed inhibit the release of ACh from guinea-pig ileum. The presence on cholinergic nerve terminals, therefore, of receptors with affinity for these purine nucleotide agonists must be accepted. The same arguments which support a role for ATP functioning as a physiological modulator of the release of ACh could well apply to CoA. We have shown that in all circumstances where ATP might fulfil a modulatory role, CoA is at least as effective. The source of purine-like compounds might indeed be the 'purinergic' nerve; however, in view of the apparent difficulties in distinguishing structurally between cholinergic and 'purinergic' axons³, this does not seem likely.

CoA could fulfil the role of the endogenously-released modulator; it is present in cholinergic nerve terminals in amounts which have been claimed to be as much as ten times higher than the amount of ACh¹⁷. Even if this value is an overestimate, the nature of the reactions involved in the synthesis of ACh in cholinergic nerve terminals dictates that there should be at least equimolecular quantities of CoA and ACh. Choline acetyltransferase (ChAT, EC 2.3.1.6) utilises choline and acetyl-CoA as its substrates in a bi-ordered Theorell–Chance type of reaction^{18,19} to yield ACh and CoA as products. The concentrations of CoA

in the cytosol of cholinergic nerve terminals must not only match the ACh concentration but, since the same extra-mitochondrial pool of CoA is the precursor of the substrate Acetyl-CoA, and since this substrate has been shown not

Table 1 Effect of purine nucleotides on ACh output of resting and electrically stimulated guinea-pig ileum in the absence and presence of theophylline

Agonist	ACh output ($\text{mol} \times 10^{-12} \text{ g}^{-1} \text{ min}^{-1}$)	
	Resting	Stimulated (0.2 Hz, 1 ms)
Control	25.9 ± 1.0	73.3 ± 3.2
Control + Theo (100 μM)	34.6 ± 1.2 (+33.5%)*	85.8 ± 2.8 (+14.6%)
ATP (2.0×10^{-6} M)	13.9 ± 0.9 (–46.3%)	20.8 ± 0.9 (–71.6%)
ATP + Theo.	26.2 ± 3.3 (+1.2%)	39.4 ± 0.9 (–46.2%)
AcCoA (2.0×10^{-6} M)	15.0 ± 2.0 (–42.1%)	40.8 ± 1.6 (–44.3%)
AcCoA + Theo.	27.4 ± 3.4 (+5.8%)	63.5 ± 1.7 (–13.4%)
CoA (2.0×10^{-6} M)	10.4 ± 1.1 (–59.8%)	33.4 ± 1.4 (–54.4%)
CoA + Theo	25.6 ± 3.3 (–1.2%)	56.1 ± 2.3 (–23.4%)
3'5' diPO ₄ (2.0×10^{-6} M)	13.1 ± 2.5 (–49.4%)	41.4 ± 5.2 (–43.5%)
3'5' diPO ₄ + Theo	23.7 ± 3.1 (–8.5%)	57.8 ± 3.9 (–21.1%)

Acetylcholine output was assayed according to Paton and Vizi⁹ with modifications. Physostigmine sulphate (5.0×10^{-6} M) was present in the 10-ml test bath to prevent hydrolysis of ACh. Morphine sulphate (1.5×10^{-5} M) and physostigmine sulphate (2.5×10^{-9} M) were present in the 10-ml assay bath to reduce endogenous ACh release and to increase the sensitivity of the assay preparation to ACh. Responses to standard solutions of ACh containing the final concentrations of the agonists used in the test bath were obtained on the assay preparation and standard curves established. Aliquots of 0.2–0.5 ml from the test bath were removed following 30-min test periods for either resting or stimulated conditions and assayed on the assay preparation. ACh outputs in stimulated conditions are expressed as the total stimulated output minus the appropriate resting output.

*Results, expressed as $\text{mol} \times 10^{-12} \text{ g}^{-1} \text{ min}^{-1} \pm \text{s.e.m.}$, were calculated from the pooled results from three to five experiments. Percentage increases (+) or decreases (–) in ACh output were calculated from the appropriate control output.

to be the rate-limiting substrate for the ChAT reaction²⁰, the CoA concentration may, in fact, be greater than the ACh concentration. Were CoA (or a derivative) to be released from cholinergic nerve terminals, it would not be detected by the firefly luciferase method because that enzyme has a high degree of specificity for ATP. The amount, therefore, of purine-like compound released on stimulation may have been greatly underestimated. In addition, the same breakdown products which allowed the inference of ATP release¹ to be made would result from the degradation of CoA.

If CoA (or any other purine nucleotide) were to be released from cholinergic nerve terminals on stimulation and function as an inhibitory modulator, the production of either an excitatory or an inhibitory junction potential at the muscle would result depending on the balance between the concentrations of ACh and the inhibitory modulator. Such a balance could be dependent on the frequency of stimulation, the distribution of receptors or differential rates of breakdown or uptake of the two mediators. This concept might be useful in explaining the occurrence of both excitatory and inhibitory junction potentials following stimulation of non-adrenergic inhibitory nerves^{5,21}.

These results do not demand that CoA itself be the endogenous modulator. In fact, our studies showed that adenosine 3'5'-diPO₄, a compound likely to result from the breakdown of CoA, was more potent than CoA itself. Equally, it is possible that the compound which represents the penultimate step in the synthesis of CoA, dephospho-CoA (preliminary studies have shown activity equal to CoA), could act in this role.

This study raises the distinct possibility that CoA, released from cholinergic nerve terminals may function as the modulator of ACh release—a purine nucleotide brake and suggests that the 'purinergic' nerve hypothesis of Burnstock³ as well as some of the characteristics of cholinergic nerve transmission should be re-examined.

This study was supported by the MRC of Canada. We thank Miss M. Ackerman for technical assistance and Dr C. W. Gowdey for helpful discussions. F.K.O. is the recipient of a Mid-West Nigerian Government Scholarship.

Localisation of gastrins to neuro- and adenohypophysis

SEVERAL peptides including substance P^{1,2}, somatostatin^{3,4}, the enkephalins^{5,6} and cholecystokinin (CCK)^{7–10} have been found both in nerve cells of the brain and in endocrine cells of the gut. CCK was first demonstrated in brain tissue by a gastrin radioimmunoassay as a peptide different from and smaller than heptadecapeptide gastrin⁷. Using six different gastrin antisera, Dockray provided strong evidence that the reported gastrin immunoreactivity⁷ corresponded to the COOH-terminal octapeptide of CCK⁸, which reacts with certain gastrin antisera because of the identical COOH-terminal pentapeptide sequences of gastrin and CCK. Studies using antisera specific for CCK without cross-reaction with gastrin have now confirmed that CCK is present in large quantities in the brain^{9,10} and that the peptide originally demonstrated by gastrin antisera⁷ indeed corresponded to the COOH-terminal octapeptide of CCK. In contrast, no peptides similar to any of the known molecular forms of gastrin have so far been found in brain tissue. We have used various sequence-specific antisera to distinguish between gastrin and CCK, and we report here that true gastrin also is present in the central nervous system. The only region of the brain containing significant amounts of gastrin was the hypophysis cerebri. Both pituitary lobes contained molecular forms of gastrin closely resembling those found in antrum¹¹.

Extracts were prepared from the central nervous system of pigs. Tissue pieces from different regions, weighing between 0.02 and 2 g, were boiled in water (0.1 g ml⁻¹) at pH 6.6 for 20 min, homogenised and centrifuged (2,000g, 20 min). After decantation of the first supernatant 0.5 M acetic acid was added to the boiled tissue precipitate for further 15 min, followed by homogenisation and centrifugation (2,000g, 20 min). Using specific radioimmunoassays for gastrin and cholecystokinin the concentrations in the mixed supernatants were measured. The only region containing immunoreactive gastrin in significant amounts was the hypophysis (Table 1). Extracts of porcine adenohypophysis, neurohypophysis, of the pituitary stalk and the hypothalamus were applied to calibrated Sephadex G-50 columns monitored by five different sequence-specific gastrin and CCK radioimmunoassays.

Three components of gastrin were found by gel chromatography of extracts from the anterior lobe, posterior lobe and stalk of the pituitary (Fig. 1). The components eluted in positions corresponding to component I, gastrin₃₄ and gastrin₁₇. The gastrin₃₄- and gastrin₁₇-like peaks were biphasic, corresponding to sulphated and nonsulphated hormonal forms¹⁷. The immunochemical identity of the gastrin₁₇-like peak was corroborated by the results obtained with antiserum L-6, specific for intact gastrin₁₇ (ref. 14) (Fig. 1b), and with antiserum 1295 specific for NH₂-terminal sequence of gastrin₁₇ (ref. 15) (Fig. 1c). The pituitary extracts also contained a fragment corresponding to sequence 1–13 of gastrin₁₇ (ref. 15) eluted immediately before gastrin₁₇ (Fig. 1c). CCK was not present in the pituitary lobes, but small concentrations were found in the pituitary stalk (Fig. 1d, e) together with the gastrins. Only very small amounts of gastrin, undetectable by chromatography, were found in hypothalamus (Table 1 and Fig. 1a). In contrast, large amounts of CCK in different molecular forms were present in hypothalamus (Table 1 and Fig. 1). One large molecular form was eluted immediately after the void volume; a small peak eluted as the tritriacontapeptide (CCK₃₃); a larger peak appeared immediately before the salt peak, presumably corresponding to the COOH-terminal dodecapeptide; a major fraction of the immunoreactivity corresponded to the COOH-terminal octapeptide of CCK₃₃; and finally a peak corresponding to the COOH-terminal tetrapeptide of CCK₃₃ appeared with an elution constant (K_{av}) of 1.30. Measurements in extracts of bovine and rat hypophysis revealed true gastrins similar to those described in the pig.

Although proof of structural identity between antral and pituitary gastrin requires sequence analysis of the gastrin-like material from the pituitary gland, several lines of evidence support the contention that the pituitary gastrins are very much alike and probably identical with antral gastrins: (1) Four antisera specific for different sequences of gastrin₁₇ reacted to the same extent with the gastrin-like components in pituitary extracts (Fig. 1) as they do with the antral gastrins^{11,14,15}. (2) By chromatography the elution constants of antral¹¹ and pituitary gastrins were identical (Fig. 1). However, the pituitary gland contained relatively more large molecular forms, component I and gastrin₃₄, than antrum¹¹. (3) Trypsin cleaved the larger molecular forms of gastrin in the pituitary extracts to gastrin₁₇-like material (Fig. 2) in a way similar to that observed for gastrins of antral origin^{18,19}. As previously suggested²⁰, it is likely that the two larger molecular forms, component I and gastrin₃₄, are biosynthetic precursors of the principal gastrin, the heptadecapeptide.

The results presented here add a new hormone to the list of peptides located both in the central nervous system and in the gut. Compared to the other peptides on this list gastrin displays specific features. The regional distribution within the brain is unique in that significant amounts of gastrin were present only in the hypophysis. The other regions of the central nervous system contained no gastrin (Table 1). Brain-gut peptides such as substance P²¹, somatostatin²², neurotensin²³, vasoactive intestinal polypeptide²⁴⁻²⁶ and CCK (Fig. 1 and Table 1) are all present in substantial amounts in the hypo-

Fig. 1 Gel chromatography of immunoreactive gastrins and cholecystokinins in extracts from porcine pituitary and hypothalamus. *A*, Adenohypophysis; *B*, neurohypophysis; *C*, pituitary stalk; *D*, hypothalamus. Frozen pieces of tissue were boiled for 20 min in water (0.1 g tissue ml⁻¹) and homogenised, centrifuged and the supernatant decanted. Equal volumes of 0.5 M acetic acid were added to the tissue which was again homogenised and centrifuged. Aliquots of 1.5 ml of the mixed supernatants from each region were applied to Sephadex G-50 superfine columns (10 × 1,000 mm) eluted at 4 °C with 0.02 M barbital buffer, pH 8.4, containing 0.1% bovine serum albumin at a flow rate of 4 ml h⁻¹. Fractions of 1.2 ml were collected. The columns were calibrated with ¹²⁵I-albumin (void volume, *V*₀) pure sulphated porcine gastrin₃₄ (*V*_{G34-s}), pure sulphated and non-sulphated porcine gastrin₁₇ (*V*_{G17-s} and *V*_{G17-n-s}), pure porcine cholecystokinin₃₃ (*V*_{CCK33}), synthetic porcine cholecystokinin₈ (*V*_{CCK8}), synthetic COOH-terminal tetrapeptide of gastrin and cholecystokinin (*V*_{G4}), and ²²NaCl (total volume, *V*_t). Each sample applied to the column was mixed with trace amounts of ¹²⁵I-albumin and ²²NaCl for internal standardisation. The concentration of immunoreactivity in each fraction was measured by five different radioimmunoassays: *a*, A gastrin assay using antiserum 2604-8, which reacts with the COOH-terminal half of gastrin₁₇ and shows poor reactivity with CCK (<0.002, ref. 12). Antiserum 2604-8 measures component I, gastrin₃₄ and gastrin₁₇ with equimolar potency¹³. *b*, A gastrin assay using antiserum L-6, specific for intact gastrin₁₇ (ref. 14). L-6 is thus not capable of binding either component I, gastrin₃₄ or CCK. *c*, A gastrin assay using antiserum 1295, specific for the NH₂-terminal sequence of gastrin₁₇ (ref. 15). 1295 is thus not capable of binding either component I, gastrin₃₄ or CCK, but binds only gastrin₁₇ and the naturally occurring NH₂-terminal tridecapeptide fragment of gastrin₁₇. *d*, An assay using antiserum 2609, specific for the COOH-terminal tetrapeptide common to both gastrins and CCKs¹². Antiserum 2609 consequently binds both gastrins and CCKs. Monoiodinated ¹²⁵I-synthetic human gastrin₁₇ was used as tracer¹⁰ and pure porcine nonsulphated gastrin₁₇ was used as standard (except in the hypothalamic extract, where CCK₃₃ was used as standard with antiserum 2609). *e*, A CCK assay using antiserum 4698, specific for sequence 25-30 of CCK₃₃. Thus 4698 binds no gastrins, but reacts with CCK₈ and all larger molecular forms of CCK. ¹²⁵I-CCK₃₃ was used as tracer and pure porcine CCK₃₃ was used as standard³³.

Fig. 2 Gel chromatography of immunoreactive gastrin in extracts from porcine adenohypophysis. Extraction procedure, column chromatography and assay as for Fig. 1. *a*, Elution of an extract containing (atypically) only component I (*V*_{C1}) and gastrin₃₄ (*V*_{G34-s}), but not detectable amounts of gastrin₁₇ (*V*_{G17-s}, *V*_{G17-n-s}) as measured with gastrin antiserum 2604. *b*, Elution of another sample from the same extract after incubation for 20 min at 20 °C with trypsin (Worthington trypsin TPCK, 10 μg ml⁻¹). Trypsin cleavage was terminated by boiling for 10 min, after which the sample was applied to the same column as used for the nontrypsinised sample. The fractions were assayed using gastrin antiserum 2604.

thalamus and other regions of the brain. The differential distribution of gastrin is of particular interest in relation to that of CCK. CCK is present in most brain regions except the epithalamus, cerebellum, and pituitary (Table 1), whereas gastrin is present only in a region free of CCK. We have previously given evidence of a common evolutionary origin of gastrin and CCK in both endocrine cells and neurones²⁷. How and why the common ancestor in antrum and hypophysis develops exclusively to gastrin but in jejunum and the remaining brain to CCK is an intriguing question characteristic for the APUD concept²⁸. The dual localisation of gastrin to both anterior and posterior pituitary lobe is another unusual property, apparently also shared by neurotensin²³. This observation suggests that gastrin is either confined to both endocrine cells (in the adenohypophysis) and nerve terminals

(in the neurohypophysis), or is located in the pars intermedia. Prolactin has also been located to endocrine cells in the adenohypophysis and to nerve terminals, but the nerve terminals were found in hypothalamus²⁹.

The amounts of gastrin in nervous tissue, the pituitary and vagal nerves³⁰, are far below the amounts of gastrin present in antral and duodenal mucosa¹¹. Circulating gastrin thus originates almost exclusively from the antrum and duodenum, and serum gastrin concentrations are reduced more than 10-fold by antro-duodenectomy^{31,32}. The functions of pituitary and vagal gastrin are therefore more likely to be related to local neurotransmitter activity than to more remote effects of the hormones.

I thank Bodil Basse and Gitte Holløse for technical assistance. Antisera were gifts from Drs J. H. Walsh and G. J. Dockray. Peptides for calibrations were gifts from Professor R. A. Gregory and Dr H. J. Tracy, Professor V. Mutt and Dr J. S. Morley. This work was supported by the Danish MRC.

Dual action of erbium on transmitter release at the frog neuromuscular synapse

LANTHANUM-D¹⁻³ and praseodymium⁴ produce very rapid and large increases in miniature endplate potentials (m.e.p.ps) but they also abolish the induction of transmitter release by nerve impulses—endplate potentials (e.p.ps). We show here that erbium (Er³⁺) also a lanthanide has a similar dual action.

The frog sartorius nerve-muscle preparation was used for this study. Intracellular electrodes (3 M KCl, 10–20 MΩ resistance) were inserted into the superficial fibres of the muscle at room temperature. The preparations were perfused continuously by a Ringer solution of the following composition: 112 mM NaCl, 0.4 mM CaCl₂, 5 mM MgCl₂, 24 mM Na CO₃OH, pH 7.2–7.4, which blocks transmission and prevents contraction.

Addition of 5×10^{-4} to 10^{-3} M Er^{3+} (ErCl_3 dissolved in the same Ringer and buffered with HEPES, $\text{pH} = 7$) caused an immediate increase of the m.e.p.p., to a frequency too high to be measured, in the first 2 or 3 min (Fig. 1) and an abolition of e.p.p., without any modification of the postsynaptic potential. These effects were not reversed after washing for 45–60 min in normal Ringer. Er^{3+} at between 5×10^{-4} and 5×10^{-5} M usually caused (depending on the fibre) a rapid increase in m.e.p.p. frequency; after a further 10 to 15 min the m.e.p.p. frequency fell to a level lower than the control (Fig. 2) and remained at that level during a 45 min washing out. At the same time there was an abolition of e.p.p. with a recovery after 20–30 min washing out. These effects remained essentially the same when tetrodotoxin (2×10^{-7} g l^{-1}) was added to the Ringer or, in Ca^{2+} -free Ringer. For the very low Er^{3+} concentration of 15×10^{-6} M the response was a rapid diminution of the quantum content of e.p.p. which remained at this low value, while m.e.p.p. frequency showed no modification or diminished slightly only when the quantum content was at its lowest values (Fig. 3). It should be noted that we never observed the increase of m.e.p.p. frequency associated with an initial

Fig. 1 Effect of 6×10^{-4} M Er^{3+} on m.e.p.p. frequency: *a*, before Er^{3+} ; *b*, after 1 min in 6×10^{-4} M Er^{3+} ; *c*, after 3 min 30. The frequency rises immediately but the maximum frequency is delayed. With 10^{-3} M Er^{3+} this effect is instantaneous.

decrease followed by an increase of quantum content described by Alnaes and Rahamimoff⁴ with the same concentration of praseodymium (but these authors worked with 10–12 mM Mg^{2+}).

The mechanisms of this concentration-dependent action of Er^{3+} are not clear. As Heuser and Miledi² and Miledi⁵ pointed out for lanthane, it seems possible that lanthanides block evoked transmitter release because, by an unknown mechanism, they prevent the inward flux of Ca^{2+} (as the propagated action potentials in synaptic nerve terminals are not blocked², it is not possible to infer a depolarisation block which could have been responsible of both the increase in m.e.p.p. frequency and the abolition of e.p.p.). This effect has been noted in various preparations, and is most marked in frog sartorius⁶. Er^{3+} action on m.e.p.p. and e.p.p. at very low concentrations can be very well explained by this hypothesis. But how does one account for the increase in m.e.p.p. frequency for greater concentrations if no Ca^{2+} can enter the membrane? It has been supposed⁴ that an influx of lanthanides in the nerve terminal would block Ca^{2+} sequestration by the mitochondria, increasing the $[\text{Ca}^{2+}]$ in the cytoplasm of the terminal and enhancing spontaneous release. Although it is well known that Er^{3+} acts on isolated mitochondria at very low concentrations⁷ it seems that this instantaneous action of lanthanides on the whole cell is too fast

Fig. 2 Effect of Er^{3+} 2×10^{-4} M *a*, Very rapid increase of m.e.p.p. with progressive decline which remains during washing. *b*, Very rapid abolition of e.p.p., but they reappear after 15 min washing in normal Ringer whereas m.e.p.p. frequency is still diminished.

to be explained by this mechanism. Moreover, it is generally accepted that lanthanides remain exclusively extracellular^{8,9}, concentrating in the synaptic folds^{2,10}. However, it has been claimed that there is a slow uptake of rare-earth ions into the axoplasm¹¹, although, here again, this uptake takes hours and nothing is observed in the first few seconds. For this last reason the possibility of an internal screening effect which, following the hypothesis of thermal collision between the membrane and the vesicles, has been supposed to be responsible for enhancement of spontaneous release by multivalent cations¹², seems also, at least for lanthanides, untenable.

A further hypothesis could be supported by the action of the lanthanides on the Na^+ channel; the lanthanides increase the nerve spike duration at Ranvier's node¹³ and crayfish giant axon¹⁴—probably by a sustained activation of the sodium conductance. As it is known that an increase in intracellular $[\text{Na}^+]$ increases Ca^{2+} influx this could be responsible for the facilitation of m.e.p.p. frequency. There are three reasons against this interpretation. First, uranyl, which also prolonged the nerve action potential, enhanced both spontaneous and evoked potentials¹⁵. Second, to test the action of the Na channel, we showed that there is no modification of the enhancement of m.e.p.p. frequency by Er^{3+} in the preparation blocked by tetrodotoxin. So it seems that an increase Ca^{2+} influx by the Na channel is not responsible for the action on spontaneous release. Interestingly, tetrodotoxin does not alter modification of

Fig. 3 After the introduction (arrow) of Er^{3+} 15×10^{-6} M, the m.e.p.p. frequency diminishes slightly only when the quantum content (*m*) is very low. Stimulation frequency 0.5 H.z. M.e.p.p. frequency and *m* are calculated with a moving bin of 1 min.

spontaneous release by presynaptic polarisation¹⁶. Third, we found that the action of Er^{3+} still persists in Ca^{2+} -free Ringer.

We suggest that the action of lanthanides on transmitter release is best explained by the hypothesis of a dual site of action of Ca^{2+} on the terminal axon. A phasic action is specific for the phasic release normally induced by nerve impulses¹⁷; this could be the "late Ca channel" of Baker *et al.*, which is inhibited by lanthane¹⁸. Second, a tonic action is responsible for the basic spontaneous rate of release. The tonic action is not strictly Ca -dependent¹⁷. Lanthanides, then, (like other divalent cations) could have a non-specific action on spontaneous release, by means of an external screening effect. This would modify the transmembrane electric field, as d'Arrigo pointed out for crayfish axon¹⁹, and possibly enhance the spontaneous data of release, without any ion influx. The maintenance of a slow rate of spontaneous release, after some minutes and after washing, could be then caused by a new value of the transmembrane potential caused by some ionic rearrangement connect to the nonspecific but tightly bound Er^{3+} . The reappearance of e.p.p. could be explained if the Er^{3+} responsible for the competition with the specific Ca^{2+} site could be more easily washed out.

The finding that a very low concentration of Er^{3+} can block the specific sites of evoked release without acting on spontaneous-release seems a very strong argument in favour of our hypothesis.

Monolayer coupling in sphingomyelin bilayer systems

THE transmission of information across biological membranes is of obvious importance. In the past, discussions of possible mechanisms for transmembrane linkage, in the absence of transport or permeation, have centred on the role of the integral membrane proteins, which function as receptors¹. When the lipids have been discussed in this context, the speculations have centred on their influence on the proteins, by way of a 'viscotropic' effect², induced by changes in ionic strength³ or temperature; that is, it has generally been implicitly assumed that the two lipid monolayers act independently of each other⁴. A detailed nuclear magnetic resonance (NMR) study of the thermal behaviour of small single-walled vesicles composed of synthetic phosphatidylcholines has shown that this is indeed the case for these systems⁵. In this report, we present evidence

that vesicles composed of another class of phospholipid, sphingomyelin, do exhibit coupling between the two monolayers, and thus could be involved in transmembrane communication in biological systems.

Phosphatidylcholine-sphingomyelin molecular differences and their relationship to differences in various physical properties have recently been discussed in some detail^{6–10}. The important difference for this study is that the two methylene chains of sphingomyelin molecules are unequal in length. One chain is part of the sphingosine base, and thus has a fixed length which extends about 13 carbons into the bilayer from the interface region^{6,9}. The other is a fatty acid acylated to the amine of the sphingosine. The fatty acid composition varies according to the source, but 16, 18 and 24 carbon fatty acids are the predominate species^{11,12}. There is therefore a chain length difference of about 3, 5 or 11 carbons, respectively. This is in contrast to the situation for natural glycerophospholipids, which, when the fatty acid composition^{11,12} and the chain shortening effect of the *cis* double bonds are taken into account, are not expected to have markedly asymmetric chain lengths. The limited amount of work done on chain pairing in phosphatidylcholines has shown a rough correlation between the chain lengths of the fatty acids of a given molecule^{13,14}. The chain length asymmetry of sphingomyelin molecules has been implicated as being a possible factor in the usual calorimetric behaviour of natural and mixtures of synthetic sphingomyelins, which do not follow the simple, ideal phase rules applicable to phosphatidylcholine mixtures. For example, the transition temperature of *N*-lignoceryl (C24:O)-sphingomyelin is found to be lower than that of *N*-stearoyl (C18:O)-sphingomyelin⁷. Another consequence of the chain length asymmetry is that the longer acyl chain could extend beyond the midpoint of the bilayer, interdigitating into the other monolayer, which would provide a mechanism for the coupling of the monolayers. The evidence given below indicates that this coupling does occur for *N*-lignoceryl (C24:O)-sphingomyelin.

The experimental approach employed by Sillerud and Barnett⁵ to study monolayer coupling of phosphatidylcholines utilised two properties of trivalent, paramagnetic lanthanide ions: the well-known fact that they can be used to separate the resonances due to molecules on the outside of small single-walled vesicles from those of molecules on the inside¹⁵, and that the binding of these ions to the phosphatidylcholine head groups increases the thermotropic transition temperature¹⁶. Sillerud and Barnett monitored this transition using several different parameters under various conditions, and found that the transition temperature of the outside monolayer can be shifted without changing the temperature of the inside monolayer transition⁵. For this preliminary communication, we have reported only the choline methyl proton line widths, since these resonances give good outside/inside resolution, are of high and constant¹⁷ intensity through the phase transition, and show a reasonably sharp break at a temperature (hereafter referred to as the onset temperature) which corresponds well to the onset temperature of the thermotropic transition of small single-walled vesicles, as monitored by calorimetry¹⁸. We have found, as was to be expected, that the ions do not need to be paramagnetic in order to increase the onset temperature, as La^{3+} , which is diamagnetic, also produces the same effect. In our experiments, we have used mixtures of La^{3+} and Pr^{3+} , as concentrations of paramagnetic Pr^{3+} which give outside monolayer onset temperature increases of 5 °C or more also produce excessive line broadening, so that accurate line width measurements become more difficult.

In their proton NMR study on dimyristoylphosphatidylcholine vesicles, Sillerud and Barnett used Pr^{3+} to phosphatidylcholine ratios of up to 0.3, for which the outside monolayer onset temperature increase is 2.2 °C (ref. 5). We have repeated their experiment using dipalmitoylphosphatidylcholine vesicles and a larger total La^{3+} phosphatidylcholine ratio of 2.4 (the $\text{La}^{3+}/\text{Pr}^{3+}$ ratio was 1.7). The outside monolayer transition temperature was increased by 7 °C. Within the accuracy of the

Fig. 1 Temperature dependence of the choline methyl proton line widths of small single-walled vesicles composed of (a) *N*-lignoceryl (C24:0)-sphingomyelin and (b) *N*-stearoyl (C18:0)-sphingomyelin. ○, Outside (downfield) resonance line width in the absence of trivalent ions; □, line width of the resonance due to molecules on the inside of the vesicles in the presence of lanthanide ions; Δ, outside resonance line width in the presence of La^{3+} . The $\text{La}^{3+}/\text{Pr}^{3+}$ ratio was 1.9. The total La^{3+} sphingomyelin ratios were a, 2.2; b, 2.7. Sphingomyelin concentrations were: a, 38.4 mM; b, 29.3 mM; as determined by phosphate analysis. The vesicles were prepared by sonication above the transition temperature in 2-min bursts to optical clarity in 50 mM KCl in D_2O . The samples were centrifuged only briefly to remove titanium particles, and were therefore not homogeneous. Fourier transform NMR spectra were measured at 100 MHz using a JEOL PS-100 P/EC-100 spectrometer. A $180^\circ\text{-}\tau\text{-}90^\circ$ pulse sequence was used to reduce the intensity of the residual HDO resonance²⁴. Conditions used were: 40 scans, 1,000 Hz sweep width, 8K data points, 4.1-s acquisition time, 30- μs 90° pulse, delay between the pulse and the start of acquisition 1,050 μs . The temperature was set using the JEOL VT/3B temperature controller: The temperature was measured before and after each set (2) of spectra with a Yellow Springs Instrument thermistor No. 44016 set in an NMR tube. The precision of the temperature measurements is estimated to be $\pm 0.2^\circ\text{C}$ and the accuracy $\pm 0.5^\circ\text{C}$. The temperatures taken as representing the onset of the thermotropic transition are indicated with arrows. The error limits for the line width measurements are: without La^{3+} , $\pm 0.2\text{Hz}$ above and $\pm 0.4\text{Hz}$ below the onset temperature; with La^{3+} , $\pm 0.4\text{Hz}$ above and $\pm 0.8\text{Hz}$ below the onset temperature.

temperature measurements (0.5°C), there was no change in the onset temperature of the inside monolayer from that observed for both monolayers in the absence of trivalent ions (39°C).

Figure 1a presents evidence that the inside monolayer onset temperature is affected by increasing the outside monolayer onset temperature for *N*-lignocerylsphingomyelin. When the outside onset temperature was increased by 9°C , the inside onset temperature increased by 3°C relative to the onset temperature in the absence of trivalent ions. This partial coupling of the two monolayer transitions remained roughly the same as the trivalent ion/phospholipid ratio was varied. For example, when the outside monolayer onset temperature was increased by 5°C , the inside onset temperature increased by

1°C . The evidence that this effect is due to chain length asymmetry is shown in Fig. 1b, in which data for *N*-stearoylsphingomyelin are plotted. Up to 9°C , increases in the outside monolayer onset temperature produced no measurable effect on the inside onset temperature. In experiments to date, the detailed shape of the outside monolayer line width curve below the onset temperature was not entirely reproducible. We therefore attach no significance to the differences seen between the outside monolayer line width curves for *N*-stearoyl and *N*-lignocerylsphingomyelin. The onset temperatures themselves are, however, completely reproducible.

For these studies, it is important to note that no appreciable fusion or leakiness occurred during the course of the descending temperature runs. This was deduced by re-running the samples at the highest temperature. The line widths, chemical shifts and the integrated intensities of the choline methyl proton resonances (inside/outside ratio), and the fatty acid methylene proton resonances, were within experimental error of the values determined for the initial high temperature spectrum. It should be emphasised that the La^{3+} /phospholipid ratios used in these experiments were much higher than those normally used to produce measurable chemical shifts. For example, a Pr^{3+} /sphingomyelin ratio of 0.07 produces a choline methyl proton shift of 0.6 p.p.m. in beef brain sphingomyelin vesicles⁸. Thus, whereas the control experiments do not categorically exclude the presence of small amounts of La^{3+} inside the vesicles, or alternately, a small proportion of leaky vesicles, the controls would certainly be sensitive to ion concentrations high enough to cause temperature changes.

To suggest possible biological relevance for monolayer coupling, it is necessary to look beyond the systems studied here, as trivalent ions are not found in significant concentrations in biological systems, and as the effect of divalent ions (for example, Ca^{2+}) on zwitterionic phospholipids is difficult to detect¹⁹. However, Ca^{2+} is known to affect markedly the phase transition of charged synthetic phospholipids³, and, more importantly, the fluidity of bilayer systems containing mixtures of neutral and charged natural phospholipids²⁰; and two of the three classes of glycosphingolipids, the gangliosides and the sulphatides, are charged. The glycosphingolipids as a group are components of all mammalian plasma membranes²¹, and they are thought to exist exclusively in the outer monolayer²². Moreover, they have been implicated as being involved in processes such as cell-cell recognition, cell division and transformation, and toxin binding²⁰⁻²³, which can affect membrane fluidity in a manner analogous to the way ions affect it, and, given monolayer coupling, could bring about the transmission of this information to the cell interior.

This work was supported by USPHS grants GM-14628, GM-17452 and HL-17576. We thank Drs Sillerud and Barnett for a pre-print of their work.

ATP levels modify the activation of the Na pump by external cations in squid axons

It has been proposed that, during the cycle of ATP hydrolysis, the (Na+K)ATPase goes through a 'closed' or 'occluded' conformation¹. This would be produced on the active site for K translocation following dephosphorylation, and, while it lasts, the dephosphorylating cation would remain attached to the enzyme, preventing rephosphorylation. The stability of this conformation varies with the dephosphorylating cations (the more stable complex follows the sequence $\text{Ti}^+ > \text{Rb}^+ > \text{K}^+ > \text{Cs}^+ > \text{NH}_4^+ > \text{Li}^+$). In addition, the complexes are less stable with increase in the ATP concentration¹. Flux experiments in human red cells²⁻⁴ and squid axons^{5,6} have produced some evidence in line with this. Unfortunately, in these cases one cannot be sure if the observed effects were solely the consequence of changes in ATP or were influenced by simultaneous modifications of the ADP and inorganic phosphate content of the cells. We have avoided such difficulties here by using squid dialysed axons, and have found an increased effectiveness of NH_4^+ over K and Rb, and of K over Rb, in activating the Na pump when internal ATP is reduced. This followed the same pattern described for their effects on the levels of phosphoenzyme. Our results suggest the existence of an ATP-sensitive occluded conformation of the Na pump formed after dephosphorylation.

We considered that if the concept of the closed conformation is correct, then the lower the ATP concentration in the cell, the more difficult it should become for a cation with a stable complex with the enzyme to activate the pump from the external side. As the Ti solubility in chloride media is extremely low, and the use of Li would require a large reduction in external Na, the chosen activating cations were K^+ , Rb^+ and NH_4^+ . The washout of internal ATP and other nucleotides was accomplished with excellent results by using glass dialysis capillaries without any metabolic inhibitor. In addition, the ADP resulting from the hydrolysis of exogenous ATP was buffered by adding 5 mM phosphoarginine to the dialysate. As the Na-Na exchange requires the presence of both ATP and $\text{ADP}^{2,6}$, this flux was expected to be minimal with the phosphoarginine buffering system.

Some components of Na efflux other than the Na-K pump would vary at low and high ATP. The Na-Ca and Na-Mg exchange are negligible at low ATP, but considerable at high ATP (ref. 8 and L. J. Mullins and F. J. Brinley, unpublished data). The Na-Ca exchange is abolished in the absence of internal Ca (R. DiPolo, unpublished data). Therefore, all dialysis solutions were Ca-free and contained 1 mM EGTA. The Na-Mg exchange would not be abolished at high ATP and its presence will have to be considered when comparing K-free effects in axons containing low and normal ATP (this would tend to reduce the K-free effect in high ATP axons).

Figure 1 describes a typical experiment. After the washout

period, and on readdition of ATP at 50 μM concentration, the total Na efflux rose to about 7 $\text{pmol cm}^{-2} \text{ s}^{-1}$. Under these conditions, and at a concentration of 10 mM, NH_4^+ was twice as effective as K in promoting an Na efflux above the K-free levels, while Rb did not produce any detectable activation. The rise in the ATP to 3 mM in the dialysate produced an increase in the total Na efflux to about 26 $\text{pmol cm}^{-2} \text{ s}^{-1}$ in 10 K artificial seawater (ASW). A new test on the sensitivity of Na efflux to the external K and K-like cations showed a completely different response: K was at least as effective as NH_4^+ , while at the same time Rb produced a distinct activation over the K-free levels amounting to 50% of that produced by equal concentrations of K. This differential effect of the external cations on Na efflux at low and high ATP is also well illustrated in Table 1, which summarises experiments on three axons. With 50 μM ATP, NH_4^+ is on average 2.6-fold more powerful than K and more than 6-fold more powerful than Rb. On the other hand, with ATP at 3 mM concentration, K becomes at least as good an activator as NH_4^+ , whereas activation due to Rb reaches as much as 70% of that due to NH_4^+ .

The extent to which these effects are due to changes in the maximal rate of Na efflux and to alterations in affinities of the external site toward the activating cations remains unclear. Other experiments (not shown) indicated that the reduction in ATP levels indeed modified those apparent affinities, with the $K_{1/2}$ for [K]_o decreasing from about 8 mM at 5 mM ATP to about 1 mM at 50 μM ATP. The effects reported here at K, Rb and NH_4^+ concentrations of 10 and 20 mM, therefore seem much more likely to be due to alterations in the maximal rate of pumping than to those affinity changes.

Also noticeable in Fig. 1 is the reduction in the K-free effect (fractional drop in the total Na efflux on removal of external K)

Fig. 1 The effects of internal ATP on the external monovalent cation activation of Na efflux in a dialysed squid axon (axon 270577-A, 475). The composition of the dialysis solution was (mM): Na^+ , 66; K^+ , 310; Mg^{2+} , 4 in excess of the ATP concentration; Tris^+ , 5; Cl^- , 79; aspartate⁻, 310; EGTA⁴⁻, 1; glycine, 330. The osmolarity was 980 mosm and the pH (20 °C) 7.1. ATP and phosphoarginine (PA) were obtained from Boehringer as sodium salts; they were neutralised with Tris (ATP) and HCl (PA) to pH (20 °C) 7.1 and stored as 250 mM solutions at -90 °C. The ATP solution contained in addition 250 mM of MgCl_2 . The Na^+ concentration referred to above is that acquired after the addition of all constituents and was maintained at the same concentration regardless of the amounts of ATP and PA. The composition of the standard artificial seawater was (mM): Na^+ , 440; K^+ , 10; Mg^{2+} , 50; Ca^{2+} , 10; Tris^+ , 10; Cl^- , 580; EDTA⁴⁻, 0.1. The osmolarity was 1,050 mosm and the pH (20 °C) 7.6. The removal or replacement of external K was made without changing the other constituents. At zero time, the dialysis began with the indicated solution plus radioactive Na. The apparent rise in Na efflux between 0 and 12 min does not represent a real flux increase, but the time taken for the isotope to reach steady-state distribution. The reduction which follows is a consequence of the ATP washout. The external solution flow was about 1 ml min^{-1} at a temperature of 17.5 °C. ●, Levels of flux indicated on the left ordinate axis; ○, flux indicated on the inserted axis. More details on the dialysis technique can be found in ref. 7.

Table 1 Stimulating effect of cations on sodium efflux at different ATP concentrations

	50 μ M ATP			3 mM ATP		
	K	Rb	NH ₄	K	Rb	NH ₄
270577-A	0.43	<0.1	1.0	1.06	0.5	1.0
280577-A	0.32	0.15	1.0	1.03	0.75	1.0
280577-B*	—	0.23	1.0	—	0.88	1.0
Mean	0.38	<0.16	1.0	1.05	0.71	1.0
Relative to K	1.0	<0.42	2.63	1.0	0.68	0.95

*The stimulating cation concentration was 20 mM. In all other cases the concentration was 10 mM.

The general experimental procedure, including ATP depletion and repletion, is described in detail in the legend for Fig. 1. The individual values for the cation-activated Na efflux were normalised in relation to those with NH₄⁺ as the activating cation. In the last row, the means normalised in relation to K activation are given.

which followed the reduction in ATP. From the total number of experiments carried out, the average K-free effect decreased from 0.38 ± 0.03 (s.e.m.) ($n = 15$) with 3–5 mM ATP to 0.13 ± 0.04 ($n = 9$) with an internal ATP of 20–50 μ M. In no case was a reversal of the K-free effect seen (larger Na efflux in K-free than in K-containing seawater). Such reversal was reported in conditions which not only reduced the ATP levels, but also must have had large amounts of ADP and inorganic phosphate²⁻⁶. This seems to indicate that the reversal response is a partial relief of inhibition (by removing external K) of a Na-Na exchange which requires ATP and ADP. In the present experiments then, one sees the responses of the pump activation solely as a consequence of changes in ATP.

This brings the present experimental conditions closer to those of *in vitro* ATPase reported by Post¹.

Our results therefore agree with the idea of enzyme-cation complexes with different degrees of stability formed after dephosphorylation. With an apparent K_m for phosphorylation of about 1 μ M ATP⁹, it is obvious that these experiments describe an ATP effect on a regulatory or control site with much lower affinity (see also ref. 1). This control site regulates the stability of the occluded conformation, and through that, the further events of ATP binding, phosphorylation and cation translocation.

Transmission of Creutzfeldt-Jakob disease with scrapie-like syndromes to mice

THE transmission of Creutzfeldt-Jakob disease of man, one of the subacute spongiform virus encephalopathies¹, to guinea pigs^{2,3} and to hamsters⁴ has been reported from this laboratory; Brownell *et al.* have also claimed transmission of Creutzfeldt-Jakob disease to mice^{5,6}. Here we present

evidence that mice are susceptible to this transmissible encephalopathy and that there are similarities between the clinical and pathological findings in experimental Creutzfeldt-Jakob disease in mice, and those observed in the same host in experimental scrapie⁷⁻¹¹.

Eleven 2-month-old Swiss mice (an outbred CD1 strain, obtained from Charles River and bred at Yale) were inoculated with 0.05 ml intracerebrally and 0.1 ml intraperitoneally (i.p.) of a 10-fold diluted normal saline suspension of brain from a guinea pig which developed Creutzfeldt-Jakob disease during the second passage of the disease. Clinical disease appeared in mice between 334 and 631 d after inoculation. From two diseased mice showing subtle clinical signs, and killed at 391 and 464 d, a similar suspension was prepared and the same amount of inoculum as that used in the first passage was again injected into seven mice of the same age and strain intracerebrally and i.p. (second passage). Signs of disease occurred during the second passage between 402 and 549 d after inoculation. No reduction of the incubation period between the first and second passage in mice was observed. A third passage is in progress and 10 weanlings and 12 adult mice of the same strain were again inoculated from material originating from a mouse which developed a scratching syndrome during the second mouse passage.

Fig. 1 Mouse in process of scratching back of neck. Note destruction of skin. This lesion developed in last 2 weeks of disease.

The clinical signs and syndromes that developed in experimental Creutzfeldt-Jakob disease in mice are similar to those described in mice inoculated with scrapie⁷⁻¹¹. Most of the inoculated mice had ruffled coats, arched backs, dullness, reluctance to move, and uncoordinated movements of the hind legs. Occasionally hyperactive animals were noted running in the cages, especially when handled. These clinical signs were subtle, nonspecific and of relatively short duration (2–4 d). All these signs have been described by Chandler^{7,8} and Pattison and Smith¹⁰ in mice inoculated with scrapie.

In the first passage of Creutzfeldt-Jakob disease in mice, two of eleven, and in the second passage, five of seven animals, developed a scratching syndrome. These mice violently and compulsively pawed at and scratched the upper part of the back in the lower cervical and upper thoracic regions. The scratching caused the skin to become excoriated, ulcerated and covered with bloody scabs (Fig. 1). The scratching syndrome lasted up to 2 weeks. The animals also licked, nibbled, and chewed the paws of the forelimbs in stereotype fashion. Scratching at exactly the same region has also been recorded in individual mice inoculated with scrapie¹². Scratching was a prominent feature in the mice inoculated with scrapie by Morris and Gajdusek⁹ and the authors drew a parallel "to the reactions

Fig. 2 Cortex. Spongy changes with increased numbers of glial cells (microglia and astrocytes). Only a few neurones remain (examples shown by arrows). Staining by haematoxylin and eosin. $\times 655$.

seen in sheep with scrapie¹³ and attributed by Gordon to itching¹³.

Five of the eleven animals of the first passage were found dead, at 334, 369, 449, 557 and 588 d after inoculation. One of these mice developed the scratching syndrome, but others died without showing any detectable clinical signs. The six remaining mice of the first passage were killed at 386, 391, 463, and 631 d, one mouse had the scratching syndrome and the remaining five had only subtle clinical signs. During the second passage, one mouse with the scratching syndrome was found dead, four with the scratching syndrome were killed at 516, 521, 538 and 549 d, and two with only subtle signs were killed 445 and 456 d after inoculation. Changes in body weight were not grossly apparent in the mice infected with the Creutzfeldt-Jakob agent.

Gross and microscopic examination of the skin in affected mice did not show any mites or other parasites. Our mouse colony at Yale is totally free of any ectoparasites. At autopsy, two animals of the first passage and one mouse of the second passage showed a conspicuous and maximal dilation of the urinary bladder. Dickinson recorded the same finding in mice inoculated with some strains of scrapie¹⁴.

No gross findings were detected in the central nervous system. Microscopic lesions, however, were similar to those recorded in mice infected with scrapie¹⁻¹². Neuronal and astrocytic changes and status spongiosus were present in mice inoculated with the Creutzfeldt-Jakob agent. These

Fig. 3 Caudate nucleus. Severe spongy changes (vacuoles), neuronal loss and several pale astrocytes (examples shown by arrows). Staining by haematoxylin and eosin. $\times 610$.

lesions were observed predominantly in the cerebral cortex, basal nuclei and thalamus (Figs 2 and 3). The cerebellum, mesencephalon and pons were mildly affected. Degenerative changes and loss of nerve cells were more pronounced in the convexity than in the base of cerebral cortex. In the cerebral cortex as well as in the basal nuclei, several small vacuoles were seen in the neuropil. No definitive vacuoles in the white matter were observed and no senile (amyloid) plaques were seen. Concomitant with the neuronal loss, there was a moderate increase in numbers of astrocytes. A mild to moderate increase in microglial cells could also be seen in affected regions. No diffuse or perivascular infiltrates composed of lymphocytes or plasma cells could be detected in our slides. In mice of the second passage, the distribution and type of lesions were similar to those described in the first passage.

None of the four control mice inoculated with normal guinea pig brain developed any of the above signs and syndromes and on microscopic examination they showed no central nervous system changes. The possibility that the above clinical signs and the lesions in mice infected with the Creutzfeldt-Jakob agent are due to contamination with scrapie can be excluded, as no investigator at Yale has been or is currently working with scrapie and no members of our laboratory have ever been exposed to this agent.

Now that Creutzfeldt-Jakob disease has been transmitted to mice, it will be possible to make many detailed comparisons with scrapie which would otherwise be impossible. Since there are several strains of the scrapie agent, each with its own variant of the disease, it is conceivable that Creutzfeldt-Jakob disease transmitted to guinea pigs, hamsters and mice may display similar variants; some of these Creutzfeldt-Jakob strains may be closer to the scrapie agent than others.

α -Crystallin polypeptides as markers of lens cell differentiation

THE acquisition of specific biochemical characteristics during cell differentiation is thought to be due to differential gene activation, and the vertebrate eye lens provides a useful tool for investigation of the process^{1,2}. The lens arises from epithelial cells arranged in a monolayer at the anterior side of the organ and on differentiation they pass through an elongation zone, becoming fibre-like concomitant with a large increase

Fig. 1 Schematic drawing of a vertebrate eye lens. Cells in the epithelial layer divide and contribute to the elongating cells that are displaced to the lens cortex.

in volume and rapid synthesis of crystallins (Fig. 1). One of the prominent lens proteins, α -crystallin (composed of subunits αA_1 , αA_2 , αB_1 and αB_2)³ has been suggested as a marker for various biological processes, particularly terminal differentiation, because changes in the subunit composition occur during the transition from epithelial to fibre cells. Delcour and Papaconstantinou reported a change in the stoichiometry of the αB_2 and αA_2 chains of α -crystallin during differentiation from 1:2 in the epithelial cell to 1:3 in the lens fibres⁴. However, changes in subunit composition also occur with ageing of the fibre cell due to the alteration of pre-existing subunits in that

αA_1 and αB_1 probably arise from deamidation of αA_2 and αB_2 ^{5,6}. Furthermore, other chains are formed by post-translational degradation starting from the C-terminus of pre-existing polypeptides^{7, 8}. We have now studied protein synthesis in two different parts of the epithelial monolayer and found further evidence for differential gene activation such that in the central region more αB_2 is synthesised than αA_2 .

Epithelial cells were labelled for 15 h with L-³⁵S-methionine (25 μ Ci, specific activity 180 Ci mol⁻¹) in labelling medium (Hanks' basic salt solution supplemented with 10 % dialysed calf serum and amino acids except for methionine). For each incubation the epithelial cells from ten capsules were used. A maximum of 25 % of the radioactivity added was incorporated. After incubation protein was isolated by freezing and thawing of the epithelial cells which had been transferred previously to water.

Electrophoresis was performed in the first direction on polyacrylamide gel containing 6M urea in 13-cm tubes as described before⁹. The gel was then sliced longitudinally as described before¹⁰. The inner slice was used as the sample gel for the run in the second dimension on a sodium dodecylsulphate polyacrylamide gel according to Laemmli¹¹. This slice was kept in position by pouring a stacking gel solution (5 % acrylamide) on top of the gel slab. Gels were autoradiographed for 72 h. Kodak X-ray RP/R2 film was used.

Hitherto the αA_2 chain has been considered to be quantitatively the most important α -crystallin polypeptide. Our experiments with fibre-free epithelial cells clearly show (Fig. 2) that before the onset of fibre differentiation αB_2 was the predominant α -crystallin subunit. The ratio of αB_2 to αA_2 was as

Fig. 2 Autoradiography of two-dimensional polyacrylamide gel electrophoresis patterns of newly synthesised protein in calf lens epithelial cells. *a*, Autoradiograph of products synthesised *de novo* in the central part of the lens epithelium. *b*, Autoradiograph of the products synthesised *de novo* in the outer edge of lens epithelium (outer edge is the region between the arrows in Fig. 1). *c*, Stained pattern of isolated native α -crystallin chains and the main polypeptide of β -crystallin βB_p . The amount of radioactivity in αA_2 and αB_2 was measured by cutting out the corresponding spots in (a) and (b) and counting the isolated samples in a liquid scintillation counter.

Fig. 3 (Left). The products newly synthesised in the reticulocyte cell-free system supplemented with lens fibre polyribosomes (a) compared with the products formed in the central epithelium (b). The heterologous system was incubated as described before¹². Electrophoresis was carried according to Laemmli¹¹.

Fig. 4 (Right). Sodium dodecyl sulphate-polyacrylamide gel electrophoresis of newly synthesised lens proteins. a, Non-cultured isolated central epithelium; b, central epithelium cultured on the lens capsule; c, central epithelium cultured on plastic; d, central epithelium cultured on capsules and preincubated with actinomycin D (5 µg ml⁻¹) for 16 h. (The same pattern was obtained with non-cultured cells.)

high as 3:1 in the central epithelium whereas in the outer region of the epithelium a ratio of 2:3 was observed.

To investigate further the mechanisms involved we have compared the pattern of protein formation in lens fibres and epithelial cells. We used lens fibre polyribosomes translated in a reticulocyte lysate because lens fibre cells cannot be maintained in culture. We have already shown that the complete set of lens fibre proteins is synthesised in this cell-free system¹² (Fig. 3). Preincubation of epithelial cells with actinomycin D, in a concentration that inhibits RNA synthesis (5 µg ml⁻¹), left the ratio of newly synthesised α -crystallin chains αA_2 and αB_2 virtually unaffected. The ratio of α -crystallin to non-crystallin proteins also remained unaffected (Fig. 4d). This rules out the possibility that different messenger stabilities are responsible for the observed stoichiometry of the αB_2 and αA_2 chains in the central epithelial cells or for cessation of α -crystallin synthesis in cells grown on plastic¹³. It seems more likely that differential gene activation is involved.

DNA polymerases during postnatal myocardial development

THE rate of mitotic division of cardiac muscle cells declines rapidly during late embryonic and early postnatal development¹⁻³ *pari passu* with a progressive restriction in proliferative capacity^{2,3}. Adaptation of adult myocardium to increased functional demand is thus limited to hypertrophy, that is, an increase in size of individual cells without a change in their number. In contrast, non-muscle cardiac cells (interstitial and endothelial cells) retain their capacity to proliferate in response to appropriate stimuli⁴. The mechanisms controlling proliferation in the developing myocardium are not known. Several investigators have noted, however, a close temporal correlation between the age-dependent decline in mitotic activity and reduced levels of enzymes involved in DNA synthesis⁷⁻⁹. The possibility has been raised⁵ that this enzyme loss is, in fact, responsible for the inability of adult myocardial cells to undergo mitosis. Here we describe differential changes in the activities of DNA polymerases from cardiac muscle and non-muscle cells during the postnatal development of the rat heart and suggest that changes in these enzymes are not sufficient explanation for the restriction in proliferative capacity.

Experiments were carried out using male Holtzman rats aged 1-240 d. Myocardial cells were separated from non-muscle cells by a modification of Young's procedure¹⁰; muscle cells make up 93-97% of the final preparation (as judged by microscopy), and 85-90% of these extrude Trypan blue. The proportion of muscle cells does not differ in the age group studied. A progressive increase in the number of both muscle and non-muscle cells was noted with advancing age (Fig. 1). The increase in myocardial cell number reached a plateau near the second week of life, whereas the number of non-muscle cells continued a slower rise till adulthood. The ratio of non-muscle to muscle cells increased from 0.81 at day 1, to 4.2 in adulthood (6 months old).

Three different forms of DNA-dependent DNA polymerases were separated by differential centrifugation (Fig. 2), and on the basis of their sensitivities to *N*-ethylmaleimide, 100 mM NaCl, 50 mM phosphate, and ability to utilise synthetic templates. They correspond to polymerases α , β , and γ , described in other tissues¹¹. Although it has been thought that polymerase α is primarily involved in DNA replication, whereas polymerase β is concerned with DNA repair, assignment of physiological roles to the different forms of the myocardial enzyme is, at present, conjectural.

Figure 1 shows the age-dependent course of myocardial DNA polymerase activity expressed as units per mg protein. Although slight differences exist between the three polymerases, all show a progressive decline with age. The preferential decrease in polymerase α activity reported by Claycomb⁸ was not confirmed either by us or by Huebscher *et al.*⁹.

The results differed significantly when the number of cells in the preparation studied was taken into consideration (Table 1). Although a 35% decline in polymerase activity was noted between days 1 and 240, this is considerably smaller than that previously reported^{8,9} or what might be

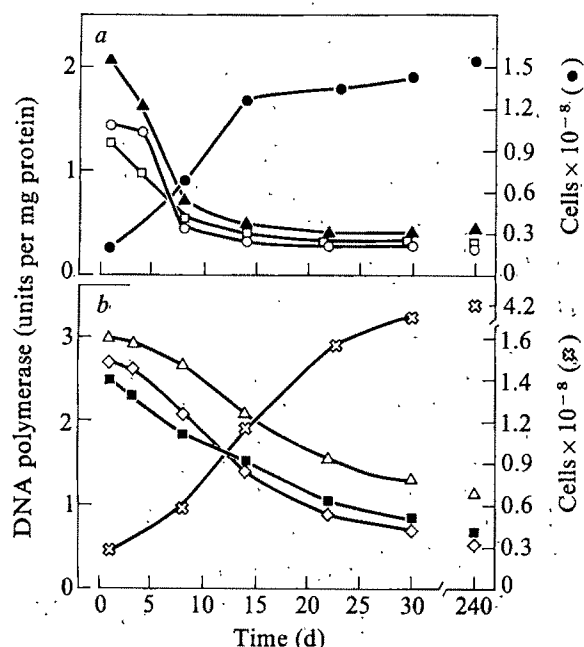

Fig. 1 Time course of DNA polymerase activities of myocardial (a) and non-muscle cells (b). The reactions were carried out for 30 min at 37 °C as described in Fig. 2. Results for polymerase α (▲, △), β (○, ◇) and γ (□, ■) are given for six experiments in each age group; one DNA polymerase unit incorporates 1 nmol ^3H -TTP into acid-insoluble material per hour. The time course of the increase in the numbers of muscle (●) and non-muscle (⊗) cells is also shown.

expected from Fig. 1. The reason for this discrepancy may be that, during this time period, significant changes take place in both the number and size of cardiac cells. Expression of enzymatic activities as units per mg protein would therefore overestimate the decline in DNA polymerase activities with age. In addition, most of the decrease in DNA polymerases occurred during the first 10 d, with a subsequent levelling off. Studies by Neffgen and Korecky¹² on anaemic rats, and by Dowell and McManus¹³ with the aortic constriction model, have clearly shown that at 3–4 weeks of age rat myocardial cells retain a significant capacity for proliferation in response to increased work load; at 6 months of age, this capacity is lost despite no significant interim change in DNA polymerase activity (Table 1). Obviously, factors other than the DNA replicative enzymes must be involved. This is also suggested by the fact that DNA polymerases from non-muscle cells show a significant age-dependent decline (Fig. 1) when expressed as units per mg protein. This is surprising in view of the fact that non-muscle cell number increases during the same period; and that non-muscle cell proliferation in response to stimuli is possible through adulthood^{12,13}. The dilemma is readily resolved by the data in Table 1 which fail to demonstrate a fall in DNA polymerase activity of interstitial cells with age.

Two distinct processes take place during the early stages of postnatal development. One is the decline of mitotic activity as the (predetermined) number of cardiac cells is reached. This probably is a process common to all organs as they reach their normal cell complement and is reflected

in the rapid decrease in ^3H -thymidine incorporation into myocardial cells and, perhaps, the decline in DNA polymerase α activity. The second process is concerned with the loss of the capacity of the myocardium to respond to increased demands with an increase in cell numbers (hyperplasia). The mechanisms involved are unknown but our results indicate that a decline in DNA synthetic activity is not an adequate explanation. In fact, a limited increase in DNA content of myocardial cells does occur with cardiac overload in adult animals¹⁴, even though it does not result in mitosis.

Increasing polyploidism of myocardial nuclei with age¹⁵ or in response to increased functional demands¹⁶ is a reflection of the same phenomenon. The undisputed restriction of mitotic capacity of adult cells may be secondary to changes

Fig. 2 DNA polymerases from rat left ventricular myocardium. Isolated cardiac muscle cells were separated according to Young¹⁰ and were homogenised in a solution containing 10 mM phosphate buffer (pH 7.5), 10 mM KCl, 1.5 mM MgCl₂ and 0.5 mM dithiothreitol. The homogenate was centrifuged at 100,000g for 1 h at 0 °C and the supernatant was layered on top of a 5–20% sucrose (w/v) gradient in 0.1 M KH₂PO₄ (pH 7.2), 0.1 M KCl and 1 mM dithiothreitol. After centrifuging for 16 h at 100,000g, fractions were collected and assayed for DNA polymerase activity. The assay medium for polymerase α contained 20 mM KH₂PO₄ (pH 7.2), 0.1 mM EDTA, 0.5 mM dithiothreitol, 10 mM MgCl₂, 200 $\mu\text{g ml}^{-1}$ 'activated'¹⁷ calf thymus DNA, 8×10^{-5} M each of dATP, dCTP, dGTP and 1.6×10^{-5} M ^3H -TTP (0.5 Ci mmol⁻¹). The assay for polymerase β was carried out in 50 mM Tris-HCl (pH 8.5), 0.1 M KCl, 10 mM MgCl₂, 1 mM dithiothreitol, 8×10^{-5} M each of dATP, dCTP, dGTP and 1.6×10^{-5} M ^3H -TTP. Finally, the medium for polymerase γ contained 50 mM Tris-HCl (pH 8.5), 50 mM KH₂PO₄ (pH 8.5), 0.13 M KCl, 0.5 mM MnCl₂, 1 mM dithiothreitol, 50 $\mu\text{g ml}^{-1}$ poly (rA):(dT)₂₅₋₃₀ and ^3H -TTP. The reaction was routinely carried out at 37 °C for 30 min and was stopped with 0.5 ml 1 N NaOH, 100 μg heat-denatured calf thymus DNA and 1 mg serum protein. The incorporation of ^3H -TTP into DNA was measured as described by Lynch *et al.*¹⁸. Recovery of the polymerases present in the cardiac homogenate was 72% for polymerase α , 65% for β and 62% for γ ; there was no significant difference in enzyme recoveries between the age groups studied.

Table 1 Age-dependent changes in the activities of DNA polymerases from cardiac muscle and non-muscle cells

Age (d)	DNA polymerase activity (nmol ^3H -TTP/10 ⁶ cells)							
	α		β		γ			
	Muscle	Non-muscle	Muscle	Non-muscle	Muscle	Non-muscle		
4	43.6 \pm 3.1	52.6 \pm 4.0	26.5 \pm 3.8	32.1 \pm 4.2	12.2 \pm 2.3	19.7 \pm 5.2		
14	28.7 \pm 4.6	48.9 \pm 4.2	18.8 \pm 4.4	29.6 \pm 4.1	10.3 \pm 1.9	18.2 \pm 4.8		
28	26.9 \pm 3.2	46.9 \pm 3.7	16.3 \pm 3.3	28.7 \pm 6.0	9.8 \pm 2.2	15.3 \pm 3.7		
240	25.8 \pm 2.6	45.3 \pm 2.1	15.0 \pm 3.1	28.2 \pm 5.5	9.1 \pm 3.1	14.8 \pm 4.4		

Reactions were carried out at 36 °C for 30 min as described in Fig. 2. Results represent mean \pm s.e.m. for six experiments.

in the organisation, composition and function of myocardial chromatin. We have recently studied these parameters during the first few months of age. A progressive decrease in chromatin transcriptive capacity, susceptibility to DNase I digestion, and poly(L)lysine binding occurs in parallel with the restriction in proliferative capacity. Derivative melting profiles of chromatin showed diminished melting of DNA regions bound by non-histone proteins with a concomitant increase in histone-bound regions, as age advanced. These findings are indicative of a decline in DNA accessibility for gene transcription which accompanies and perhaps determines the loss of mitotic potential by the myocardial cells.

Photochemical (8→8) coupling of purine nucleosides to guanosine

IN comparison with the pyrimidine bases of nucleic acids, the purines are relatively inert to photochemical alteration. No photoproducts derived specifically from adenine or guanine have been isolated from ultraviolet-irradiated DNA or RNA. However, purine bases and nucleosides can be substituted at C8 by free radical species generated photochemically from simple alcohols, amines, and ethers, and these reactions may be relevant to the radiation-induced cross-linking of proteins, and other biological molecules, to nucleic acids¹. We report here that guanosine is substituted in a similar manner by the free radicals produced on photolysis of 8-bromopurine nucleosides to give compounds in which two purine nucleoside moieties are coupled together through their respective C8 positions.

In this way, we have prepared 8-(8-guanosyl)guanosine (GG), 8-(8-guanosyl) adenosine (AG), and 8-(8-guanosyl) inosine (IG); the partial characterisation of AG has been reported previously². These compounds, whose structures are shown in Fig. 1, all exhibit intense fluorescence emission in the region of 410 nm on excitation at wavelengths close to 330 nm. Their formation demonstrates the feasibility of reactions between purinyl-free radicals and purine bases and these may be important in the photochemistry and radiation chemistry of nucleic acids. Furthermore, the simple photochemical coupling reaction described here should be applicable to the synthesis of new fluorescent nucleoside and nucleotide analogues, and to the fluorescent labelling of purine polynucleotides.

Ultraviolet irradiation of equimolar mixtures (both components ~ 0.3 mM) of guanosine with 8-bromoguanosine,

Fig. 1 Structures of the (8→8) coupled purine nucleosides GG, IG, and AG.

8-bromoadenosine and 8-bromoinosine leads to the formation of the (8→8) coupled purine nucleosides GG, AG, and IG respectively. Although the reaction occurs in aqueous solution on irradiation at 254 nm (low pressure mercury lamp), higher yields have been obtained by using 30% aqueous acetone as solvent and irradiating at wavelengths > 290 nm (medium pressure mercury lamp with Pyrex filter) under nitrogen. In each case, the coupled nucleoside photoproduct has been separated from the starting materials by dry-column chromatography³ on silica gel using a solvent mixture of ethyl acetate–water–1-propanol (4 : 3 : 1, upper phase) as eluant. Subsequent purification to chromatographic and electrophoretic homogeneity has been achieved by crystallisation from water for GG, chromatography on Sephadex G-10 for AG, and preparative paper chromatography (Whatman 3 MM, 1-propanol–water, 10 : 3) for IG.

The molecular weights of GG and AG have been established by ²⁵²Cf-plasma desorption mass spectroscopy⁴. Their low field ¹H-NMR spectra (in (CD₃)₂SO containing D₂O) show that both purine bases have been substituted at C8. Thus the spectrum of GG exhibits no aromatic resonances and a doublet at δ 6.21 (J = 6 Hz) for the anomeric protons, while that of AG shows a singlet integrating for 1 proton at δ 8.19, assigned to C2-H of the adenine ring, and two doublets (J = 6 Hz) centred at δ 6.22 and δ 6.38 due to the anomeric protons of the two ribosyl groups. Consistent with their extended conjugation, the ultraviolet absorption of these compounds (Table 1) extends to much longer wavelengths than that of the parent purine nucleosides and is associated with intense fluorescence emission maxima in the range 405–415 nm.

As yet, only very limited quantities of IG have been isolated in pure form. Its structure has been assigned on the basis of its mode of preparation, and the similarity of its chromatographic behaviour and spectroscopic properties (Table 1) to those of GG and AG. Furthermore, on treatment with nitrous acid, AG is partially converted to a product chromatographically identical to IG.

The structure of GG has been confirmed by X-ray crystallography. GG crystallises from water as the tetrahydrate in

Fig. 2 The two independent molecules of GG in the crystalline tetrahydrate viewed perpendicular to the base of one half of the molecule in each case.

the form of colourless needles elongated along *b*, space group *C2* with $a = 26.69(1)$, $b = 8.425(5)$, $c = 12.286(7)$ Å, $\beta = 104.9(2)^\circ$. A total of 1,740 unique reflections were collected on a Philips PW1100 four-circle diffractometer of which 1,071 had $I(\text{rel}) > 2\sigma I(\text{rel})$ and were considered observed. The structure was solved by a multi-solution tangent refinement using the SHELX programme and refined, with all atoms treated isotropically, to a final *R* of 0.068.

There are two independent half-molecules in the crystallographic asymmetric unit, with the other halves generated by a twofold axis which runs through the centre of the bond joining the C8 atoms of the purine rings. Figure 2 shows the two independent molecules viewed perpendicular to the base of one half of the molecule in each case.

Table 1 Ultraviolet absorption and fluorescence characteristics of (8 \rightarrow 8) coupled purine nucleosides at pH 7.0

Compound	Ultraviolet absorption		Fluorescence	
	λ_{max} (nm)	ϵ ($\times 10^{-3}$)	$\lambda_{\text{max}}^{\text{ex}}$ (nm)	$\lambda_{\text{max}}^{\text{em}}$ (nm)
GG	278	24.4	330	405
	322	21.5		
AG	280	13.6	331	415
	321	18.0		
IG	278	—	326	415
	315	—		

The ultraviolet spectra were recorded using a Cary 118 instrument. The fluorescence spectra, which are uncorrected, were recorded using a Perkin-Elmer MPF-2A spectrofluorimeter.

Fig. 3 The structure of GG tetrahydrate viewed down the *b* axis. Hydrogen bonds are indicated by dotted lines.

The torsion angles χ_{CN} ($\text{O1}'\text{-C1}'\text{-N9-C4}$) (ref. 5) are 35.7° and 47.6° for molecules A and B respectively. The orientation about the glycosidic bonds is thus *syn* for both molecules, as expected for nucleosides with bulky substituents at C8 (ref. 6). In addition both A and B molecules contain *intra* molecular $\text{O5}'\text{-H} \cdots \text{N3}$ hydrogen bonds which provide additional stabilisation for the *syn* conformation.

The ribose ring conformations of the two independent molecules differ considerably. In molecule A they show a C3' *endo* puckering distorted towards a C4' *exo* conformation, with a pseudorotation parameter⁷ $P = 28.6^\circ$ (2T_4). The ribose rings of molecule B show C2' *endo* puckering distorted towards C1' *exo* conformations, with $P = 156.2^\circ$ (2T_1). The conformation about the C4'-C5' bonds in both molecules is *gauche-gauche*. The torsion angles $\text{O5}'\text{-C5}'\text{-C4}'\text{-C3}'$, $\text{O5}'\text{-C5}'\text{-C4}'\text{-O1}'$ are 59.0° , -56.8° and 47.6° , -69.3° for molecules A and B respectively. Within the individual molecules the bases are twisted about the C8-C8 bond, with the angles between least squares planes of the separate bases equal to 53.3° (molecule A) and 41.8° (molecule B). The structure consists of continuous columns of stacked bases. The interplanar distances between successive bases, measured at the C8-C8 bonds, are alternately 4.86 and 3.56 Å. The structure is extensively hydrogen bonded. The water molecules form a network of hydrogen bonds concentrated in columns about alternate twofold screw axes as shown in Fig. 3.

What's new?

Affinity chromatography

Blue Sepharose® CL-6B

is a group specific adsorbent consisting of the blue chromophore Cibacron Blue F3G-A covalently attached to Sepharose CL-6B. It has affinity for a large number of enzymes including many kinases, dehydrogenases and blood coagulation factors. Specific elution techniques preserve the selectivity characteristic of affinity chromatography methods. Blue Sepharose CL-6B also binds serum albumin and can be used to selectively remove albumin from other plasma proteins.

2'5'ADP-Sepharose 4B

is for affinity chromatography of NADP⁺ linked enzymes. Adenosine 2'5' bisphosphate is attached to Sepharose 4B via a 6 carbon spacer. This ligand offers distinct advantages over the use of NADP⁺ which may undergo structural modification during coupling and conversion to NADPH or degradation during affinity chromatography.

Poly(A)-Sepharose 4B

contains polyriboadenylic acid chains about 100 nucleotides long coupled to Sepharose 4B by multiple covalent attachment at N⁶ positions. It offers new possibilities for the chromatography of uridylic acid rich nucleic acids such as heterogeneous nuclear RNA's and many virus RNA's, and also messenger ribonucleoproteins and other proteins with affinity for RNA.

Hydrophobic interaction chromatography

Octyl-Sepharose CL-4B Phenyl-Sepharose CL-4B

Hydrophobic interaction chromatography is a new technique with exciting potential for the separation of proteins. Substances are applied to the bed under conditions which favour hydrophobic interaction, and are eluted and separated by decreasing the polarity of the eluent, using solute ions with greater chaotropic effect, adding detergents or altering the pH.

Octyl- and Phenyl-Sepharose CL-4B contain hydrophobic groups attached to the uncharged and exceptionally stable matrix of Sepharose CL. Chromatography can be performed over a wide pH range and in detergents or denaturing media such as urea and guanidine hydrochloride.

Immobilized thiol reagent

Thiopropyl-Sepharose 6B

is highly substituted with protected thiol groups for covalent chromatography of SH-containing compounds. Applications include reversible immobilization of peptides during sequencing or synthesis, reversible immobilization of enzymes and other ligands for affinity chromatography, and isolation of mercurated polynucleotides.

Further information about all of these products is available from your local distributor of Sephadex®, Sepharose® and other separation media.

Announcing a new journal from Cambridge

First Issue March 1978

The Behavioral and Brain Sciences

*An International Journal of Current Research and Theory
with Open Peer Commentary*

We live in an age of specialization. The behavioral and brain sciences, which encompass a myriad of subdisciplines ranging from molecular neurobiology to the philosophy of mind, are an excellent example of a field in which people doing closely related research find it difficult to communicate with each other. In fact you may never know of the existence of research paralleling your own interests if it is reported in specialized journals which you have not had the time to read regularly.

The Behavioral and Brain Sciences (BBS) is a new international quarterly journal designed to remedy this situation. The journal will publish research articles in any area of psychology, neuroscience, behavioral biology or cognitive science together with open commentaries, and aims to provide criticism, stimulation and unification of research across these disciplines.

The BBS concept is based on the knowledge that psycholinguists and animal learning specialists, learning theorists and behavioral biologists, social psychologists and neurobiologists, information scientists and philosophers, all have something to contribute to and learn from each other's work.

Editor: Stevan Harnad

Associate Editors: Robert W. Doty, *Rochester, U.S.A.*, John C. Fentress, *Dalhousie*, Julian Jaynes, *Princeton*, David Premack, *Pennsylvania*, Karl Pribram, *Stanford, U.S.A.*, Zenon Pylyshyn, *Western Ontario*, Barry H. Smith, *Massachusetts*, Peter Wason, *London*.

Papers scheduled to appear, with Commentary, in Volume 1, Numbers 1 and 2 of *The Behavioral and Brain Sciences*:

DALBIR BINDRA: How Adaptive Behavior is Produced: A Perceptual-Motivational Alternative to Response-Reinforcement & *Commentary*

CHARLES BRAINERD: The Stage Question in Cognitive-Developmental Theory & *Commentary*

JOHN HAUGELAND: The Plausibility of Cognitivism & *Commentary*

IRVING KUPFERMANN and KLAUDIUSZ R. WEISS: The Command Neuron Concept & *Commentary*

ZENON PYLYSHYN: Computational Models and Empirical Constraints & *Commentary*

P. E. ROLAND: Sensory Feedback to the Cerebral Cortex during Voluntary Movement in Man & *Commentary*

The Behavioral and Brain Sciences is calling for papers and for recommendations of topics and already published articles or books for Open Peer Commentary treatment. Complete instructions for preparation of manuscripts are available on request from the editorial office:

**Stevan Harnad, Editor,
The Behavioral and Brain Sciences,
P.O. Box 777, Princeton, NJ 08540. U.S.A.**

Subscription price: Institutions £35.00 (US \$60.00); Individuals £17.50 (US \$30.00) Single parts £10.00 (US \$17.00)

There is a special introductory rate for Volume 1 for subscribers in the U.S.A. and Canada: Institutions \$48.00; Individuals \$24.00. A student rate of \$16.00 is available to those who prove eligibility with their order.

Climatic shifts

John Gribbin

Climates of Hunger: Mankind and the World's Changing Weather. By Reid A. Bryson and Thomas J. Murray. Pp. xv + 171. (American University Publishers Group: London, 1977.) £6.75.

PROFESSOR BRYSON is perhaps the leading proponent of the view that anthropogenic pollution of the atmosphere is hastening the world into a pronounced cooling—at least, a little Ice Age—through the effect of aerosol particles blocking out some of the heat from the Sun. Thomas Murray is a science writer who has worked with the University of Wisconsin-Madison, where Bryson's Institute for Environmental Sciences is based. Working in harness, they have produced a book about the possible hazard to world food supplies of a significant global cooling, but one which is aimed very clearly at the general reader and the non-scientist, including, perhaps, those with some political influence on the world food situation.

The result is a very easy, even glib, read, which is strong on anecdotal material about the impact of past climatic shifts on human societies, but is weak on mechanisms of climatic change and which has no real scientific depth. It was clearly written for a purpose, to spread the message of Bryson's ideas beyond his peer group of climatologists, and even beyond the scientific ranks of those who, for example, regularly read *Nature*. It does the intended job well, as indicated by the selection of the book as a US Book-of-the-Month Club choice, but this means that someone who is a regular reader of *Nature* need feel no compunction to rush out and buy the book, but can safely wait for a paperback without missing any significant new contribution from Bryson.

This is very much a Bryson's eye-view; the casual reader will not get a balanced picture of the current climatic debate, but that is of far less importance than interesting such a reader in the debate in the first place. The balance, or lack of balance, is indicated by the reference list, where no less than 25% of the 80-odd works cited are authored or co-authored by Bryson.

The most notable omission from that reference list is Stephen Schneider's *The Genesis Strategy* (reviewed in *Nature* 264, 137; 11 November 1976)

which is still, to my mind, the best introduction to climatic change for the non-specialist. The gaps in the text of this new book which make it unsuitable as introductory reading in an academic context are typified by the devotion of only four short paragraphs to solar changes, within a mere nine-page chapter "How Climate Changes".

But the importance of all books of this kind is that they draw attention to the possibility of irregular fluctuations in natural forces which can affect world food production. The fact that the world could feed twice the present population, but yet people are starving today, indicates that something is wrong with the overall production and distribution of food. When reserve stocks are deliberately kept low to

maintain prices on world markets, the prospect of a run of bad harvests is grim, whether or not you subscribe to Bryson's detailed views on why such a pattern of events may take place. Any book which may encourage more sensible husbandry must be welcomed; I hope, however, that the likely success of this little book in its evangelical role will encourage Professor Bryson to provide us with something more technical which we can get our teeth into. The importance of his ideas certainly justifies the devotion of a major text to their display in the academic market place. □

John Gribbin is a Fellow of the Science Policy Research Unit, University of Sussex, UK.

Dissipative structures

Self-Organisation in Non-Equilibrium Systems: From Dissipative Structure to Order through Fluctuations. By G. Nicolis and I. Prigogine. Pp. xiii + 492. (Wiley-Interscience: New York and London, 1977.) £20; \$34.

THE central key word of the monograph by Nicolis and Prigogine is *Dissipative Structure*. This concept already seems to have become a paradigm, at least in theoretical biology. What is a dissipative structure? The formation of flow structures in physical systems under certain conditions is commonly known. The most frequently quoted dynamic pattern of this type is the Bénard honeycomb-like structure of a liquid heated from below; this phenomenon results from the coupling of heat flow and local convection currents. A further impressive example for spatial and temporal order in a flow structure is the Belousov-Zhabotinski reaction; here, it is the interplay between chemical reactions and diffusion that creates periodic patterns in time and space. Such flow structures exist only within certain boundary conditions and survive only on energy input dissipated in the maintenance of the flow pattern.

Such close similarities exist between the behaviour of a dissipative structure and the properties of living organisms that it is intriguing to investigate living

organisations in terms of flow interactions. The 'bioflows' are, of course, not heat flows or rarely convection flows, but the rates of coupled biochemical reactions and diffusion processes in the open systems of biology. It does seem very exciting to find out whether the various flow patterns observed in chemistry and biology are based on one and the same fundamental principle of coupling between chemical reactivity and diffusional propagation.

The book by Nicolis and Prigogine presents a concise introduction to theoretical foundations and applications of new concepts and offers to approach flow phenomena programmatically in the framework of a general dynamic theory. This introduction to the theory of dissipative structures aims at a better understanding of the evolution and survival of self-organising systems in physics and biology.

Dissipative structures have been recognised to exist only far from equilibrium where the relationships between flows and driving forces are non-linear. Thus, classical non-equilibrium thermodynamics (relating flows and potential gradients linearly) do not provide adequate tools to describe dissipative flow structures. Among the new concepts introduced by the Brussels school is the definition of a local potential which generalises the familiar chemi-

cal potential for an application to encompass non-equilibrium states. The behaviour of fluctuations in the local thermodynamic properties now permits a distinction to be made between stable and unstable states. If the potential gradients are small, each deviation from the steady-state rapidly decays to the stationary level. When the gradients become increasingly larger, however, then the fluctuations can increase beyond the instability point where a new dissipative flow structure can be established: development of order, that is, self-organisation through fluctuations.

A useful criterion for flow stability is introduced by the "excess entropy production". This entropy function is positive for stable or steady-states and negative for the evolution of a dissipative structure. As expressed in the introduction of the monograph, the authors intend to present a unified formulation for apparently very different self-organisation phenomena in complex systems. It does seem very appealing to consider such different manifestations of "flow order" as living beings, the generation of coherent light by a laser, the emergence of spatial and temporal pattern of activity in chemical kinetics and in fluid dynamics, or the functioning of an animal ecosystem or of a human society as dissipative self-organisation in far-from-equilibrium conditions. The book is therefore conceived as a basic guide.

In part one, the thermodynamic background for the description of flow phenomena is outlined and the basic principles of non-equilibrium thermodynamics are introduced, with special

emphasis on chemical reactions coupled to transport processes such as diffusion. Part two covers mathematical aspects of self-organisation using simple autocatalysis and other feedback models. Part three deals with stochastic methods for the description of fluctuations and diffusional processes. In part four, control mechanisms in chemical and biological systems are discussed: regulatory processes at the subcellular and cellular level, cellular differentiation, and pattern formation. Part five is devoted to evolution and population dynamics and touches on, among various examples, reaction networks of biopolymer self-organisation, the thermodynamics of ecosystems, neural and immune networks, social systems and epistemological questions.

The book covers an impressively broad field showing parallels and similarities in the substructure of various complex dynamic phenomena in nature. It remains true, however, that it is dangerous to project the concepts of one discipline to another field and to use analogies instead of careful analysis of the particular problem under investigation. But this enthusiastically written book by Nicolis and Prigogine—although not very easy to read for non-theoreticians—clearly elaborates to what extent structural parallels can be recognised and how general notions can be applied to very different dynamic structures in order to gain a better understanding of self-organisation.

Primate studies and methodology

Primate Ecology: Studies of Feeding and Ranging Behaviour in Lemurs, Monkeys and Apes. Edited by T. H. Clutton-Brock. Pp. xxii+631. (Academic: London, New York and San Francisco, 1977.) £25; \$41.

STUDIES of seventeen primate species make up the bulk of this important book; review chapters and appendices on methodology the remainder. Few population-orientated primate studies have been attempted and the papers concentrate on the detailed sampling of individual behaviour in one or two social groups. Interspecific, interpopulation, intergroup and interindividual differences in feeding and ranging behaviour are all discussed, as are diurnal and seasonal changes in diet. The fine level of analysis used by most

authors may prove tiresome to the non-specialist but it is fully justified. Most papers have adequate summaries.

The studies spring from a decade's speculation on the relationship between ecology and social organisation, and most contributors develop evolutionary hypotheses about the adaptive significance of behaviour. The experimental manipulation of resources is largely out of the question and the usefulness of the conclusions will rest largely on their applicability to different populations or species. Review chapters by the editor and Harvey, consider intra- and interspecific variation in ecology and behaviour.

The diets of all seventeen species are described. Clutton-Brock reviews methods for sampling feeding, Harvey reviews the measurement of dietetic diversity, and Hladik describes field methods for collecting and processing food samples. These chapters, together with each authors' attention to methodology, will make this a standard reference volume. The chemical composition of food is given by several

authors and some interesting conclusions follow. Calculations by A. Goodall confirm that a completely herbivorous gorilla could obtain ample energy and protein; but Fossey and Harcourt consider that gorillas eat grubs to get vitamin B₁₂. The consumption of ants and termites by chimps is shown by Hladik to compensate for essential amino acids lacking in plant foods. The balancing of diet during a day, between protein-rich buds and leaves and carbohydrate-rich flowers and fruit, is shown for Howlers (Smith), Orang-utans (Rodman), Siamang (Chivers) and Chimpanzees (Hladik). Primatologists are now paying attention to potentially toxic secondary compounds in food plants. Hladik argues, however, that though these compounds may protect plants against non-specialised frugivores such as macaques, they provide little protection against the specialised leaf eaters such as *Presbytis senex* in which bacterial decomposition is assured before intestinal absorption.

Another major theme discussed is the interaction between diet and social organisation. Primatologists now study the forest flora meticulously. Food trees are mapped, leaf and fruit abundance recorded and the primates' daily movements are related to changes in food availability. Some general patterns are emerging. Sussman found that the folivorous *Lemmus fulvus* lives in small groups with small ranges and uses few food species, in contrast to the more frugivorous *L. catta*. Parallel interspecific differences are seen in *Presbytis* and *Colobus*. At a finer level, the relationship between food availability and subgroup formation is reported for spider monkeys by Klein and Klein, and for chimpanzees by Wrangham. In contrast to earlier speculation, Wrangham found no evidence that the frequent dispersal and reformation of chimpanzee subgroups increases food-searching efficiency. The so called "food calls" (loud calls given by males on finding large food sources) are given most frequently when food is plentiful, not when it is scarce. Wrangham considers that a calling male "puts up" with increased feeding competition because some of the attracted animals will be potential mates.

This is a book for every library. It would be splendid if some of those reading it set out to make the population-orientated ecological studies (for example, of population dynamics) which are absent from the present volume. In the more open-country primates, these will not be as difficult as the editor implies in his introduction.

If somebody tries to sell you one, find out what's behind it.

If it's true that imitation is the sincerest form of flattery, then we're feeling very flattered indeed! Because everyone seems to be making fume cupboards like ours these days. And why shouldn't they? They're not all that difficult to make – though the original designs did take us many years to perfect!

But unfortunately for our competitors and for their customers, too – although it's easy to copy our fume cupboards, it's absolutely impossible to match our experience.

Behind every fume cupboard we make, there's over 40 years of never ending research, not just into fume cupboard design and performance, but into complete fume extraction and air input systems, as well. Which is why we don't regard the fume cupboard as just another piece of laboratory furniture. Some manufacturers do – and they're quite happy to sell you one with no questions asked.

We're not.

We want to know what it's for, where it's going, how how it's to be used... then we can provide you with a complete back up system to ensure that your fume cupboard operates with maximum safety, efficiency and economy.

So, if you just want to buy a fume cupboard, you can get one almost anywhere. But if you want to choose a fume cupboard from the widest range in Europe and then have a complete extraction system designed around it and installed by experts who've been doing it successfully for nearly 50 years, there's only one company that can help.

PRINCETON

A GUIDE TO THE BIRDS OF VENEZUELA

Rodolphe Meyer de Schauensee and
William H. Phelps, Jr.

Illustrations and facing-page notes by Guy
Tudor, with John A. Gwynne, Jr., H. Wayne
Trimm, and Michel Kleinbaum

More than forty percent of the bird species known to inhabit South America has been found in Venezuela. Here in one volume is the essential information on this rich and varied avifauna — nearly 1,300 species, almost all of which are illustrated.

52 plates, 40 in color, 41 text figures
6 x 9" • Cloth, £37.40 • Paper, £14.90

STRATIGRAPHIC ATLAS OF NORTH AND CENTRAL AMERICA

Edited by T. D. Cook

Preparation of this atlas followed nearly 60 years of geological work on the continent by members of the exploration staff of Shell Oil Company. Originally intended for use in developing new concepts relative to the occurrence of hydrocarbons, the maps and charts were designed to make available all existing data regarding the stratigraphy of North and Central America.

192 maps, 14 stratigraphic sections, 21 cross sections • 12½ x 16¾" • Cloth, £37.40
Spiralbound paperback, £11.30

THE EVOLUTION OF NORTH AMERICA

Philip B. King

REVISED EDITION

In revising his now classic work on the geology of North America, Philip B. King has devoted attention both to the new concepts of global tectonics and to the new facts obtained from fieldwork in recent years. From its overview of the natural history of continents, to the sections describing the characteristics and history of each region, this remains a fundamental text on continental geology.

Illus. • Cloth, £18.70 • Paper, £7.10

GEOGRAPHIC VARIATION, SPECIATION, AND CLINES

John A. Endler

In this study of the origins and development of geographic variation, divergence, and speciation, Endler is particularly concerned with genetic divergence as it is usually found on continents among groups of populations isolated only by distance. While earlier writers thought intense geographic differentiation and speciation required complete isolation, the author shows how they may develop in spite of continuous gene flow. Monographs in Population Biology, 10 • Cloth, £12.00 • Paper, £5.45

Standard Stereograms for Materials Science

by P T Clarke

Department of Industry

National Physical Laboratory

Analysis of the electron and X-ray diffraction patterns of crystalline materials is greatly simplified by the use of stereographic projections, but it is a prerequisite that a comprehensive series of standard projections should be available. This volume contains 223 such standard stereograms, most of which display over 300 plane normals.

The diameter of the stereograms, 200 mm, was chosen as being the largest, and hence most accurate, of the usual sizes to fit standard A4 paper and so permit the use of the most common types of copying machine.

Non-classical carbonium ions?

The Non-Classical Ion Problem. By Herbert C. Brown, with comments by Paul von R. Schleyer. Pp. 301. (Plenum: New York, 1977.) \$29.95.

THE non-classical carbonium ion is a formulation for an organic cation, no one structure for which, written with normal two-electron bonds, adequately describes the properties observed. One carbon atom (or more) is assigned a coordination number exceeding four, and some of the bonds are considered partial, and dotted; precise definition presents some difficulty. Proposed once in 1939, and freely in the 1950s, this concept came under rigorous scrutiny by the Purdue school, who agreed that it was acceptable *a priori* but asked whether it was needed, or whether the rapid interconversion of classical structures would explain observations more economically. An unusually vigorous controversy ensued, in which organic chemists not themselves involved have taken the opposed views, either that it was a sterile question attracting attention better directed

elsewhere, or that it represented an important stage in the development of chemical theory, like the debate on tautomerism in about 1900. Documents published before mid-1965 were issued in reduced format, inter-related by a commentary by P. D. Bartlett, in 1966.

Now we have a full statement of the case for the prosecution, written in 1976-77 by H. C. Brown, with shorter comments by P. von R. Schleyer as advocate for the defence. Whatever else is said, the idea has encouraged non-classical formats in publication.

The subject is important, and this book is an excellent summary of the field. Much progress has been made. Brown's concept of equilibrating classical ions is now proved for many sys-

tems, and some early views on steric effects are now undisputed. On the other hand, the phenonium ion, attacked by Brown in 1962, is now accepted, along with the knowledge that solvolysis reactions generally involve nucleophilic assistance from solvent (thanks largely to Schleyer). At last Brown can write of "Coate's cation" (see Figure): "the proposal that solvolysis proceeds through the non-classical ion appears reasonable"; so the way is now open to agreement on effects to be expected from substituent and solvent changes in such species.

The debate is not over; even where Brown and Schleyer agree, the reader may decide to differ. He will, however, find this book readable and cogent throughout, and he will be able to move about it, checking points with the aid of a good index. He will be repeatedly reminded of the fundamental aims of organic chemistry. He will reach his own conclusions, and will probably end by deciding that the great controversy was worthwhile, after all.

M. C. Whiting

M. C. Whiting is Professor of Organic Chemistry at the University of Bristol, UK.

Prostaglandin synthesis

The Synthesis of Prostaglandins. By A. Mitra. Pp. 444. (Wiley: London and New York, 1977.) £16.90; \$28.60.

THE field of prostaglandin (PG) synthesis has received the attention of many organic chemists over the past decade, and as a result much novel and intriguing chemistry has been developed. Abhijit Mitra has set out to bring together, in this single review, the various synthetic strategies that have been used up to the middle of 1977, and to describe many intimate details of their execution.

Taken in order, the book begins with a brief, and at times misleading, description of PG biosynthesis; the unlikely implication that thromboxane A_2 is partially converted to PGE_2 and $PGF_{2\alpha}$ *in vivo* is an example. This minor blemish apart, chapters 2-15 describe the numerous approaches to the PGE and PGF systems in a very detailed manner. The individual syntheses are classified by the particular strategy used, such as that involving 1,4-addition to substituted cyclopentenones as the "fundamental" step, and that depending on the well known Corey lactone. This system works well, and renders the information readily accessible; however, it may be that a classification based on the historical development of such ingenious synthetic chemistry would have afforded the browsing reader with

greater aesthetic rewards. Rather obscurely, one version of the synthesis of prostacyclin from $PGF_{2\alpha}$ lies buried in the chapter devoted to the Corey approach, together with a description, without references, of some prostacyclin analogues.

The remainder of the book is devoted to the synthesis of thromboxane B_2 , PGA_2 , PGC_2 , and finally, various PG analogues. This last chapter covers not only the very close relatives, such as 15-methyl- PGE_2 , but also some of the numerous heterocyclic and hetero-chain analogues that have been prepared; however, the complete lack of patent coverage, which is a significant drawback of the book as a work of reference, is very noticeable in this section. There are also some minor omissions from the published literature, such as the Upjohn *ent*-PGs, and the *seco*-PG analogues of Merck.

In summary, the book contains a very useful, if somewhat non-critical, review of the literature on PG synthesis, the coverage being generally quite comprehensive. For the synthetic chemist working in the field, the book will be an invaluable aid, with its clear and concise diagrammatic presentation and thorough indexing. For the non-specialist reader, there is described much elegant molecular architecture to be perused and enjoyed.

Truelove Lowland, Devon Island, Canada: A High Arctic Ecosystem

edited by L.C. Bliss, PhD

This first ever study of an ecosystem in these northern islands summarizes 33 research projects conducted under the auspices of the International Biological Programme. The area studied covers 16 square miles with unusually rich flora and fauna. Data are presented for the basic scientific aspects of environmental and biological function, plus, uniquely, several aspects of lake biology, the carrying capacity of these lands for the Inuit, and the impact of petroleum exploration. This basic information may be applied to land management plans for other arctic islands.

735 pages, illustrated throughout, species lists, fold-out colored maps of soils and vegetation. \$20 (Canadian) plus \$1 packing and postage.

Analysis of cell organisation

International Cell Biology, 1976-1977. Edited by B. R. Brinkley and K. R. Porter. Pp. 694. (Rockefeller University Press: New York, 1977.) \$30.

THIS volume derives from the First International Congress on Cell Biology, held in Boston in 1976. It contains shortened versions of sixty or so invited contributions to twenty-two miniature symposia which formed part of that congress. Since it deals at some length with a wide range of topics which were judged to be of particular interest at that time, the editors invite us to regard it as "a historic document of cell biology in 1976", which "future scholars should find a valuable source of information". The claim is, of course, extravagant, but let us take it at face value. What would a future scholar, perusing these pages, discover about cell biology in the mid-1970s?

The most striking impression, I believe, would be of the extent to which the analysis of cellular structure and process is being carried down to the molecular level. Cell and molecular biology are meeting and fusing. In this connection it is, I think, not out of place to quote some words of E. O. Wilson about the nature of the relationship that exists between contiguous levels of analysis in science. In a recent article he writes: "For every discipline in its early stages of development there exists an antidiscipline. For many-body physics, particle physics; for chemistry, many-body physics; for molecular biology, chemistry; for cellular biology, molecular biology; and so forth. With the word *antidiscipline*, I wish to emphasise the special adversary relationship that exists initially between the studies of adjacent levels of organisation. This relationship is also creative, and with the passage of a great deal of time it becomes fully complementary."

I believe that there can be no doubt that, in these terms, after a period of mutual indifference, if not antipathy, the creative, complementary phase of the relationship between cell and molecular biology is at hand. Indeed, the evidence for this collected here is the most impressive aspect of the present volume. Not in every article, but in a high proportion, we see that the molecular basis of cell organisation is being uncovered with considerable speed and success.

As one contributor writes, in connection with chloroplasts: "With the investigative strategies now available, nothing but the discipline of experi-

mentation is needed to reveal the interactions between individual thylakoid proteins and between proteins and lipids. The future challenge is to unravel the intricate mechanism of the assembly of chloroplast membranes from their diverse components and to explain how this assembly is controlled by the complex interaction of the chloroplast and nuclear genomes." The passage is typical, unexceptional. Note, too, that "nothing but the discipline of experimentation" is seemingly needed. This is another feature of the subject as displayed here. Cell biologists now have at their disposal a prodigious array of analytical techniques and an almost unlimited territory to explore with them. New ideas are not, for the moment, held to be the prime necessity: it is tacitly assumed that advances are assured, and will come primarily by making observations and doing experiments. One author, for example, asserts quite confidently that in the next decade with the new methods of somatic cell genetics it will be possible to map over a thousand human genes.

There are almost no theoretical articles in this volume and scarcely anyone seeks principles or generalisations that might encompass more than his own immediate area of enquiry. It is an interesting phase of the subject, bewildering and stimulating in the multiplicity of new data.

This is better than most such volumes and contains at least a few excellent papers. It will, however, have only a rather limited useful life. There is little that one cannot, with moderate diligence, find elsewhere. Some articles are confined to reporting more or less new facts; others, generally much more useful, provide a broader review of their subject. Many of the articles would have been better if they could have been longer. The symposium on secretion in animal cells achieves a degree of coherence that would have been welcome elsewhere. The editing and production are first-rate.

A. V. Grimstone

A. V. Grimstone is Lecturer in Zoology at the University of Cambridge, UK.

Laser spectroscopy

Non-Linear Laser Spectroscopy. By V. S. Letokhov and V. P. Chebotayev. Pp. 466. (Springer: Berlin and New York, 1977.) DM68; \$30.

THIS is a timely and authoritative monograph on the non-linear interaction of laser radiation fields with Doppler-broadened atomic and molecular transitions by the leaders of the distinguished Russian school of laser spectroscopists. The ability of coherent, intense optical fields to saturate a transition, to interact only with a narrow range of molecular velocities, to enhance multiphoton processes, all these and many more have opened up a qualitatively new sort of spectroscopy. Experimental resolution has often increased by several orders of magnitude and we can now observe effects unimaginable a decade or so ago. This book attempts to describe the theory and experimental methods of all those features which can be grouped loosely under the heading of "non-linear laser Doppler-free spectroscopy". The authors develop the density-matrix equations of motion for single and multiphoton absorption and apply them to a description of saturated absorption with both counter-propagating and colinear probe and saturating beams. This is followed by a discussion of Doppler-free two-photon transitions using rather

simpler theory, and a treatment of coupled three-level systems (including Raman processes). This theoretical framework is then applied to specific problems in atomic and molecular spectroscopy, with attention being given to limiting factors on resolution and on stabilisation in precision "standards" experiments.

The book is written in a rather strange grammatical style afflicted by an over-literal translation (apparently by the authors) of the Russian original. This is certainly no worse than the style of the AIP translation journals in which a great part of the original material first appeared in the West, and detracts only very slightly from the value of the book. It is a pity the authors did not include a more complete discussion of the role of the dynamic Stark effect on saturated resonance fluorescence in strong fields, a subject of great interest for the past four years or so. More generally there is little or nothing on quantum aspects of the electromagnetic field, with an emphasis on semiclassical descriptions. The typeface is the unpleasant typewriter form we are forced to accept in these depressed days, but in return the price is compensatingly realistic. In spite of these defects, the book will be of great value to laser spectroscopists and to atomic physicists contemplating using the new laser techniques.

Peter Knight

Peter Knight is Jubilee Research Fellow in the Department of Physics at Royal Holloway College, University of London, UK.

NATO Advanced Study INSTITUTES SERIES

SERIES A: Life Sciences

Major Patterns in Vertebrate Evolution

edited by Max K. Hecht, Peter C. Goody,
and Bessie M. Hecht

Presents the latest information on vertebrate evolution above the species level in those areas that are generally applicable to the entire field of vertebrate zoology. Volume 14: 908 pp., 1977, \$77.40/£40.64

Prostaglandins and Thromboxanes

edited by F. Berti, B. Samuelsson, and G. P. Velo

Internationally recognized authorities present state-of-the-science reports on the biologic role of prostaglandins and thromboxanes. Volume 13: 449 pp., 1977, \$54.00/£28.35

Nucleic Acids and Protein Synthesis in Plants

edited by L. Bogorad and J. H. Weil

Reflecting the diversity of current research in molecular biology and biochemical developmental biology in plants, this volume examines fundamental biological problems with applications in world agriculture. Volume 12: 417 pp., 1977, \$47.40/£24.89

Surface Membrane Receptors: Interface Between Cells and Their Environment

edited by Ralph A. Bradshaw, William A. Frazier,
Ronald C. Merrell, David I. Gottlieb,
and Ruth A. Hogue-Angeletti

Presents a wide perspective on the field of surface membrane receptors by exploring the similarities and differences in the inherent interaction of cells with external objects. Volume 11: 482 pp., 1976, \$47.40/£24.89

Specificity in Plant Diseases

edited by R. K. S. Wood and A. Graniti

Reviews the molecular, cellular, and genetic bases of the interactions that determine the specificity characteristic of diseases of higher plants caused by fungi and bacteria. Volume 10: 354 pp., 1976, \$42.00/£22.05

Eukaryotic Cell Function and Growth: Regulation by Intracellular Cyclic Nucleotides

edited by Jacques E. Dumont, Barry L. Brown,
and Nicholas J. Marshall

Presents an authoritative, critical evaluation of present knowledge in the field of intracellular cyclic nucleotide regulation of eukaryotic cell function. Volume 9: 838 pp., 1976, \$76.20/£40.01

Meat Animals: Growth and Productivity

edited by D. Lister, D. N. Rhodes, V. R. Fowler,
and M. F. Fuller

Consolidates research on the principles and techniques of animal husbandry, and examines the potentially important physiological capabilities that exist between and within animal species. Volume 8: 541 pp., 1976, \$51.00/£26.78

The Hepatobiliary System: Fundamental and Pathological Mechanisms

edited by W. Taylor

Examines the fundamental aspects of membrane structure and transport mechanisms, and their relation to the normal and pathological hepatobiliary system. Volume 7: 654 pp., 1976, \$59.40/£31.19

Metabolic Compartmentation and Neurotransmission: Relation to Brain Structure and Function

edited by Soll Berl, D. D. Clarke, and Diana Schneider

Describes the relationship between metabolism localization and function of neurotransmitter candidates and the morphology of the brain. Volume 6: 721 pp., 1975, \$59.40/£31.19

Tumor Virus-Host Cell Interaction

edited by Alan Kolber

Reports on theories in RNA and DNA tumor virology and documents evidence on the presence of a viral genome in human cancers. Volume 5: 461 pp., 1975, \$43.20/£22.68

Phloem Transport

edited by S. Aronoff, J. Dainty, P. R. Gorham,
L. M. Srivastava, and C. A. Swanson

Describes the anatomy, physiology, and biophysics of phloem transport, parameters most effective for measuring transport, and proposed models of the system. Volume 4: 636 pp., 1975, \$47.40/£24.89

Genetic Manipulations with Plant Material

edited by Lucien Ledoux

Eminent scientists discuss some of the exciting developments in cell engineering practice. Volume 3: 601 pp., 1975, \$57.60/£30.24

Nematode Vectors of Plant Viruses

edited by F. Lamberti, C. E. Taylor, and J. W. Seinhorst

Examines the taxonomy, morphology, ultrastructure, and ecology of virus-bearing organisms, interrelations between plant hosts and nematodes, and viral associations and diseases. Volume 2: 460 pp., 1975, \$45.60/£23.94

Vision in Fishes: New Approaches in Research

edited by M. A. Ali

An authoritative introduction to the study of vision in fishes, this volume considers the fundamental physical concepts relating vision to environmental adaptation. Volume 1: 836 pp., 1975, \$75.00/£39.38

1977 Titles in the *Biology and Environment* series

The Biology of Marsupials

Edited by Bernard Stonehouse and
Desmond Gilmore

This distinctive group of mammals is generally considered primitive, and yet marsupials show a striking plasticity of form, a high degree of ecological diversity and extensive distribution. How does a pouch compare with a placenta? How has modern biochemical analysis changed our views on the classification of marsupials? Can they compete with placental mammals and, if so, by means of what unique characteristics?

Thirty four contributors to this volume discuss such questions, and the result represents a survey of current international thinking in marsupial biology. £19.50, 0 333 18795 4

Evolutionary Ecology

Edited by Bernard Stonehouse and
Christopher Perrins

The twenty-one papers presented here are by biologists whose work has in some important way been influenced by Dr David Lack, FRS, the Oxford ornithologist who played a major role in the rapid development of the study of ecology and the evolution of birds. Four sections deal with: population regulation and functions of territory; feeding adaptations and ecological segregation; breeding adaptations and reproductive rates; and behaviour, adaptation and taxonomic relationships. Most of the papers relate to what is still a controversial issue in biology - the significance of reproductive rates.

£12.95, 0 333 19676 7

To order a copy of either of these books, please send the correct amount, plus 50p carriage, to Technical Books Services, P.O. Box 79, Maidenhead, Berkshire SL6 2EG.

APPOINTMENTS VACANT

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY LABORATORY SUPERINTENDENT

Applications are invited for the post of Laboratory Superintendent in the Department of Biochemistry.

The Department is multidisciplinary with emphasis on medicine and the pathological sciences and is very active in research. The person appointed (male or female) will be in charge of a team of about 25 technical staff and will be directly responsible to the Head of Department for the organisation and efficient operation of the laboratories and technical services for both teaching and research.

Applicants must have a relevant qualification; with wide experience in biochemical laboratory practice and techniques and should have previously held a position of responsibility in laboratory management.

The salary will be on the Senior Experimental Officer scale: £5,219 to £6,655 per annum, the commencing point according to qualifications and experience.

Applications, in the form of a curriculum vitae, giving full details of age, qualifications and experience, and the names and addresses of two referees, should be sent to the Assistant Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH, by:—March 16, 1978 and from whom further particulars of the post can be obtained: Telephone Guildford 71281, Ext. 452. 7505(A)

PROFESSOR, SENIOR LEVEL PHYSICAL/BIOPHYSICAL CHEMISTRY UNIVERSITY OF CALIFORNIA RIVERSIDE

The Department of Chemistry has a position for a distinguished person as Professor of Chemistry, effective July 1978, or later. Candidates should be internationally recognised for current research in the forefront of physical chemistry. Preference will be given to biophysical candidates who complement present research offerings (there is a potential for joint appointment in Biochemistry, if appropriate). Candidates must have demonstrated ability to make significant contributions to the undergraduate and graduate instructional programmes. We are especially interested in receiving applications from women and minority group candidates. Requests for confidentiality of applications will be honoured. Submit curriculum vitae and list of publications to: M. Gibian, Chairman, Search Committee.

Department of Chemistry
University of California
Riverside, CA 92521

An Equal Opportunity/Affirmative Action Employer. 1495(A)

MICHIGAN STATE UNIVERSITY POSTDOCTORAL RESEARCH ASSOCIATES IN ENVIRONMENTAL CARCINOGENESIS

Openings for research associates with strong background in molecular biology, biochemistry, microbiology, or biophysics to study the relationship between DNA repair, mutagenesis, and oncogenic transformation of human cells in culture by physical, chemical, and viral carcinogenic agents. Send application, including curriculum vitae, reprints, and letters of recommendation to: Dr V. M. Maher or Dr J. J. McCormick, Co-Directors, Carcinogenesis Laboratory, COM, Michigan State University, E. Lansing, Michigan 48824. 1536(A)

SECOND AIN SHAMS MEDICAL CONGRESS FACULTY OF MEDICINE Cairo

October 21–25, 1978

Ain Shams Faculty of Medicine announces its "Second Ain Shams Medical Congress" to be held in Cairo from October 21–25, 1978. This congress will include 3 days for all branches of medicine and 2 days on a special subject which will be "Immunology".

Application forms of detailed informations will be sent on request.

Please write to:

Professor Aly Abdel-Fattah,
Secretary General
Ain Shams Faculty of Medicine
Abbassia, Cairo.
P.O. Box 38, Abbassia. 1483(C)

INSTITUTE OF CELLULAR AND MOLECULAR PATHOLOGY

DEPARTMENT OF MOLECULAR BIOLOGY

Applications are invited from candidates, possessing a Ph.D. in molecular biology, molecular genetics or biochemistry, for postdoctoral or junior faculty research positions. Candidates should be interested in gene cloning and recombinant DNA research and experience in nucleic acid technology would be an advantage. The ability to speak French is not essential. Positions are available for three years.

Send curriculum vitae, list of publications and the names of three referees to Dr John Davison, Department of Molecular Biology, ICP, Avenue Hippocrate 75, B-1200 Brussels, Belgium. 1550(A)

IMPORTANT RESEARCH DIVISION OF AN INTERNATIONAL PHARMACEUTICAL GROUP

located in PARIS is offering an **EXCELLENT CAREER
OPPORTUNITY** for a

FIRST CLASS SENIOR CARDIOVASCULAR PHARMACOLOGIST

to join his **BIOLOGY DEPARTMENT**

Preference will be given to individuals with the following qualifications:

- M.D., Ph.D. degree or equivalent.
- relevant postdoctoral or industrial experience (3 to 5 years).
- significant basic research in the field of hypertension, mainly on the central and peripheral mechanisms involved in the regulation of the blood pressure.
- good attitude towards team work.
- good potential for managing people.

The applicant will be responsible to the Director of Biology.

An excellent salary and comprehensive benefit programme accompany this position.

Please send curriculum vitae to Box No. 1272(A), Nature Magazine, c/o Macmillan Journals Ltd., 4 Little Essex Street, London WC2R 3LF.

1272(A)

South African Astronomical Observatory Research Posts

Two temporary (3 year) or permanent research posts are available at the South African Astronomical Observatory which is financed jointly by the Council for Scientific and Industrial Research (South Africa) and the Science Research Council (United Kingdom). The astronomy staff of the SAAO is based in Cape Town where the main offices, etc. are situated. Most observing facilities are at Sutherland (Cape Province) where the SAAO has 1.9m; 1.0m; 0.75m and 0.5m reflectors equipped with a range of modern instrumentation.

Preference will be given to applicants with research experience and a Ph.D. degree or equivalent, and whose main interest is observational astronomy.

Salary will be determined by qualifications and experience. Assistance will be given with transfer expenses.

Fringe benefits include 39 days leave per annum (maximum), generous sick leave, and medical and pension schemes.

Enquiries should be directed to the Office of the Scientific Counsellor,

South African Embassy:

278 High Holborn, London WC1V 7HE (Tel. 01-242 1766)

59, quai d'Orsay 75007 Paris (Tel. 555-92-37)

P.O. Box 12-1366 Tehran (Tel. 62-1835/6/7)

5300 Bonn 2, Auf der Hostert 3 (Tel. 36 3047/48)

3rd Floor, 2555 M Street N.W. Washington D.C. 20037

(Tel. 833-3860)

1453(A)

CENTRE DE RECHERCHE MERRELL INTERNATIONAL— STRASBOURG (France)

A position (Ph.D.) level is available for a
**SENIOR ANALYTICAL
BIOCHEMIST**

The work involves participation in ongoing biochemical programmes and initiating and running pharmacokinetic and metabolic studies in animals and in man.

Interested persons should send their curriculum vitae to the Director, Dr Jan Koch-Weser, Centre de Recherche Merrell International, 16 rue d'Ankara, 67084 Strasbourg, France. 1478(A)

UNIVERSITY OF OXFORD CLARENDON LABORATORY RESEARCH ASSOCIATE

Applications are invited for the post of research associate in the field of beam foil spectroscopy. The work will include measurements of fine structures and Lamb shifts by the application of newly developed spectroscopic techniques to highly ionised atoms produced by the Nuclear Physics Laboratory's Tandem van de Graaff accelerators.

Applicants should have had some years' experience in experimental atomic physics research, should preferably hold or be about to obtain a doctoral degree. The appointment, for two years in the first instance, will be on the scale £2,904 to £4,811 (under review).

Applications, giving a curriculum vitae and the names of two referees, should be sent to Dr J. D. Silver, Clarendon Laboratory, Parks Road, Oxford OX1 3PU, England, by March 31, 1978. 1493(A)

PHYSIOLOGIST

required by the Medical Research Council Cyclotron Unit to join the Biology Section to work with normal tissues using experimental animals. Studies will include effects of both neutrons and X rays and certain adjuvant treatments used in radiotherapy. Experience in neurophysiology and/or pharmacology would be an advantage. Post vacant mid-April. The applicant must have a First or Upper Second Class degree in the appropriate subject and at least 3 years postgraduate research experience or a degree in medical or veterinary sciences.

Salary, according to age and experience, in the range £3,780 to £5,660 (inclusive of pay supplements and London Weighting) plus 6 weeks annual leave.

Please write, giving qualifications and curriculum vitae, to:

Miss A. Pires,
M.R.C. Cyclotron Unit,
HAMMERSMITH HOSPITAL,
Ducane Road, London W12 0HS.
Tel: 01-743 4594, ext. 103
(Ref: P/2.)

1555(A)

THE QUEEN'S UNIVERSITY OF BELFAST DEPARTMENT OF PHYSIOLOGY

Two lectureships in the department of Physiology are available from October 1, 1978 or such other dates as may be arranged, and the successful applicants will assist in teaching medical, dental and science undergraduates.

LECTURESHP

On lecturer, if medically qualified, will be appointed on the scale (under review): £4,190 to £6,655. A salary on a sessional basis may also be paid by the Eastern Health and Social Services Board for hospital services undertaken in addition to University duties. If not medically qualified the lecturer will be appointed on the scale (under review): £3,333 to £6,655. Initial placing on above scales is dependent upon qualifications and experience.

LECTURESHP ON PROBATION

Appointment to the second lectureship is subject to a period of probation of up to three years in duration and might be of particular interest to junior doctors working for a higher degree in medicine or surgery by thesis or by examination. It will be made initially at one of the points £3,975, £4,190, £4,403, £4,607, or for non-medical applicants at one of the points £3,333, £3,547, £3,761, on the scale (under review) rising to £6,655.

Assistance with removal expenses is available, and contributory pension rights under the FSSU/USS apply. Closing date: March 22, 1978. Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. (Please quote Ref. 78/N.) 1521(A)

THE UNIVERSITY OF LEEDS DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of DEMONSTRATOR in the above Department, available from May 1, 1978. The successful candidate will be expected to assist in teaching biochemistry to science and to medical students and to carry out research in association with existing members of the academic staff. The appointment is tenable until September 30, 1979.

Salary on the scale £2,904 to £4,811 of the IB Scale for Other Related Staff.

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 83/11. Closing date for applications March 17, 1978. 1492(A)

UNIVERSITY OF LONDON INSTITUTE OF PSYCHIATRY RESEARCH WORKER (Scale IA)

required for an investigation of factors controlling the enzymic N-methylation of tryptamines in rodent and human tissues. Postdoctoral experience in enzyme purification and gas chromatography desirable, but not essential. This post is supported by M.R.C. grant for three years.

Salary in range £3,975 to £4,403 per annum, plus £450 London Weighting.

Application forms and further details available from the Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF, quoting ref RR/N. Application forms should be completed and returned by 10 March 1978. 1562(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited from post-doctoral experimental physicists for a LECTURESHP in the DEPARTMENT OF NATURAL PHILOSOPHY. Applicants should have practical knowledge and experience of high-voltage technology and an interest in charged particle beams and/or plasma physics. The successful candidate will be required to participate in general undergraduate and postgraduate teaching in physics and in the research interests of the Department.

Salary scale £3,333 to £6,644 per annum (under review) with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 12/78) and enclosing a self-addressed envelope (9in. by 4in.), may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW with whom applications should be lodged by March 13, 1978. 1515(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF MOLECULAR BIOLOGY

Applications are invited for an M.R.C. postdoctoral fellowship to work on the molecular relationships of plasmids, principally those carried by enterobacteria and *Pseudomonas* species from soil and clinical sources. A variety of biochemical and genetical techniques will be involved. These will include DNA-DNA hybridisation and probably heteroduplex analysis and the generation of recombinant plasmids both *in vivo* and *in vitro*. The appointment is for three years from April 1978 or when convenient thereafter. The starting salary will be between £3,333 and £4,190 p.a. as appropriate.

Applications with curriculum vitae and the names and addresses of two referees should be sent to Dr P. M. A. Broda, Department of Molecular Biology, King's Buildings, Mayfield Road, Edinburgh, EH9 3JR. Please quote Reference 5001. 1436(A)

YALE UNIVERSITY SCHOOL OF MEDICINE NEUROBIOLOGIST

The Department of Physiology is seeking a neurobiologist at the Assistant Professor level. Preference will be given to individuals whose work relates to the function of the central nervous system. The position permits considerable time for research; opportunities exist for graduate and medical student teaching.

Please send curriculum vitae, bibliography and the names and addresses of three references to:

CHAIRMAN
Neurobiologist Search Committee
Department of Physiology
Yale University School of Medicine
333 Cedar Street
New Haven, Conn. 06510

Applications from women and members of minority groups are encouraged. An Equal Opportunity/Affirmative Action Employer.

Applications should be received before March 30, 1978. 1419(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY RESEARCH TECHNICIAN

required for work on project involving cellular immunology in the Division of Immunology, Department of Pathology. Qualifications: H.N.C. or equivalent. Experience of laboratory work in immunology, cell biology or biochemistry desirable. Salary range £2,695 to £3,087. Applications in writing to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP. 1530(A)

UNIVERSITY OF SYDNEY
PROFESSIONAL
ASSISTANTS—
GRADES I and II or
RESEARCH FELLOW
SCHOOL OF PHYSICS
(SOLAR ENERGY GROUP)

The N.S.W. State Government grant for solar energy research within the School of Physics has made possible an expansion of the research effort on selective surfaces and advanced solar collectors. Desirably the positions will be filled at the post-doctoral or equivalent experience level by experimental physicists where experience in solid state or optics would be an advantage. Appointees will be responsible to the leader of the solar energy research group for specific parts of the solar energy projects.

All appointments will be to December 31, 1978 in the first instance, but may be renewed.

Salary Range: Professional Officers \$A10,264 to \$A15,703 p.a. Research Fellow \$A14,851 to \$A19,551 p.a.

Applications including details of qualifications, experience and names of two referees by March 31, 1978, to Professor H. Messel, University of Sydney, N.S.W. 2006, Australia, from whom further information is available. 1514(A)

MEDICAL RESEARCH
COUNCIL
NATIONAL INSTITUTE FOR
MEDICAL RESEARCH
BIOCHEMIST/
MICROBIOLOGIST

A postdoctoral biochemist or microbiologist aged up to 29 years is required by the LABORATORY FOR LEPROSY AND MYCOBACTERIAL RESEARCH to study aspects of the intermediary metabolism of *Mycobacterium leprae* (the human leprosy bacillus). Quantities of bacteria sufficient to undertake such studies are available in the Laboratory for the first time.

The appointment will be for up to three years and will be in the present salary range £3,995 to £5,219 p.a. according to age and qualifications plus £450 p.a. London Allowance; superannuation provision.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA. 1488(A)

CHEMISTRY
DEPARTMENT

Applications are invited for a Post-doctoral Research Fellowship, supported by the E.E.C. Solar Energy Project D. Fund. With Dr J. M. Kelly and Professor D. C. Pepper the Fellow will study the synthesis and properties of polymer-bound coordination complexes, and assess their potential for solar energy conversion. Previous experience in polymer-, photo-, or coordination compound-chemistry would be helpful.

The salary commences at £3,483 per annum. Funds are available immediately and until June 1979.

Applications should be sent to Dr J. M. Kelly, at the Chemistry Department, Trinity College, Dublin 2, from whom further details may be obtained. 1542(A)

Research Assistant

This Laboratory provides advisory and experimental services to ICI Ltd, for the control of toxic hazards in manufacturing processes and in other fields of growing importance, such as the development of pesticides and food additives. Emphasis is placed on improving and assessing methods for studying the biological effect of foreign compounds and upon understanding mechanisms of toxicity. The provision of toxicological information, prior to product clearance and registration in many countries, is a major activity undertaken by the Laboratory on behalf of the ICI group.

We are seeking to recruit a scientist to assist in the management of the routine short-term tests for the detection of potential carcinogens. The work involves both Ames and cell transformation tests. The person

appointed, male or female, will be responsible for investigating and recommending improvements to protocols where necessary and for the analysis and recording of data. The job will involve contracting work out and the job holder will be responsible for arranging the contract and ensuring that it is of a satisfactory standard.

Requests for application forms, quoting Reference RA/EP/EL, should be addressed to:-

Miss S. C. Carson, Personnel Officer,
Imperial Chemical
Industries Limited,
Central Toxicology
Laboratory,
Alderley Park,
Nr. Macclesfield,
Cheshire.

Overseas candidates should only apply if they have a planned visit to the UK within the next two months.

1537(A)

JUNIOR TECHNICIAN "B"

required to assist in busy immunological laboratory studying pulmonary host responses to infectious agents, inhaled particles and tumours in man and animals. Applicants should hold ONC (MLS), day release granted for HNC studies. Salary on Medical Laboratory Technician Scales. Apply to The Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP, giving age, qualifications and experience. 1531(A)

UNIVERSITY OF EAST ANGLIA NORWICH DIRECTOR OF THE CLIMATIC RESEARCH UNIT

Applications are invited from persons with suitable qualifications and experience for the post of Director of the Climatic Research Unit, which is associated with the School of Environmental Sciences. This position will become vacant on the retirement of the present and founding Director of the Unit, Professor H. H. Lamb. The appointment will be at Professorial or Readership level, according to the age and experience of the successful candidate, and will be tenable from October 1, 1978, or as soon as possible thereafter. Salary will be on the Professorial scale £8,106 to £9,587 or on the Reader scale £6,443 to £7,951 (under review).

Applications (one copy only), giving the names of three persons to whom reference may be made, should be lodged with the Establishment Officer, University of East Anglia, Norwich NR4 7TJ (Telephone 0603 56161, ext. 2126) from whom further particulars may be obtained, not later than March 10, 1978. No forms of application are issued. In naming three referees you are particularly requested to give the names of those who can immediately be approached. 1523(A)

DEPARTMENT OF EDUCATION DUBLIN POSTDOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for Research Fellowships in Science (excluding Medical and Social Science) and Engineering tenable in any one of the following institutions in Ireland:—

University College, Dublin;
University College, Cork;
University College, Galway;

An Foras Taluntais
(The Agricultural Institute);

The Institute for Industrial
Research and Standards.

The Fellowships will be tenable for two years with the possibility of extension for a third year.

Applicants should hold a Ph.D. degree or have equivalent research experience or, in the case of engineers or technologists, suitable industrial experience. Candidates should not be over 30 years of age; preferably they should be under 28.

Appointments will be effective not earlier than October 1, 1978. Salary will normally be £3,495 to £3,960 per annum; awards up to £4,617 may be made to engineers and technologists whose industrial experience or other special circumstances warrant it.

Full particulars may be obtained from the Secretary, Department of Education (Headquarters Section), Marlborough Street, Dublin 1. The latest date for receipt by the Department of completed application forms is March 20, 1978. 1507(A)

I.L.R.A.D. DIRECTOR

The position of Director of the International Laboratory for Research on Animal Diseases (I.L.R.A.D.) will become vacant in June, 1978. The Director is the chief officer of the Institution and must have experience and background in disease research and in the administration of a research institution. In addition, the Director must be able to relate to a variety of staff and direct the research programmes of the Institution as well as the various other functions associated with a research programme involving both basic and disease orientated activities.

I.L.R.A.D.'s mandate is to develop effective control methods for trypanosomiasis and theileriosis, two important animal diseases that constrain livestock production in a number of developing countries. It is one of the International Research Centres supported by the Consultative Group on International Agricultural Research. The staff of I.L.R.A.D. is recruited internationally and is engaged in multi-disciplinary research activities leading to the development of immunologic or related control procedures. The I.L.R.A.D. headquarters is in Nairobi, Kenya, and is a modern research complex.

Qualified candidates are requested to submit current C.V.s as well as a synopsis of their research and administrative experiences. Included should be the names and addresses of three referees who can be contacted in support of their candidacy. This information should be submitted to the Chairman, I.L.R.A.D. Search Committee, Rockefeller Foundation, 1133 Avenue of the Americas, New York, N.Y. 10036, U.S.A. Further information can be obtained from the same address. 1559(A)

**FLOUR MILLING AND BAKING
RESEARCH ASSOCIATION
CHEMISTS AND BIOCHEMISTS
STATISTICIAN/MATHEMATICIAN**

The Flour Milling and Baking Research Association carries out a wide range of research and service work for the Milling and Baking Industries and holds a number of research contracts for the Ministry of Agriculture, Fisheries and Food. The laboratories are situated in an attractive semi-rural area on the edge of the Chilterns with ready access to London.

Several positions are available for graduates with strong research backgrounds who would be interested in carrying out basic and applied research on cereal problems.

PROTEIN CHEMIST/BIOCHEMIST

fundamental studies on cereal proteins

ORGANIC CHEMIST/BIOCHEMIST (two posts)

natural product chemistry

CHEMIST/ANALYTICAL CHEMIST

application of modern chemical/physical analytical techniques

BIOCHEMIST

nutritional and toxicological studies

STATISTICIAN/MATHEMATICIAN

statistical and mathematical service for the

Research Association

Applicants should have a Ph.D. degree and further research experience. For the post of Statistician/Mathematician a B.Sc. or equivalent or postgraduate qualification in statistics or mathematics together with several years applied experience is required.

Starting salary will depend on qualifications and experience within the Senior Scientific Officer (c. £4,350 to £5,810 p.a.) or Principal Scientific Officer (c. £5,620 to £7,120 p.a.) scales. There is a pension scheme and assistance with relocation expenses will be given where appropriate.

Further details can be obtained from Professor Brian Spencer, Director-General, Flour Milling and Baking Research Association, Chorleywood, Herts. WD3 5SH. Telephone: 092 78-4111. Applications, with the names and addresses of three referees, should be submitted by March 20. 1404(A)

**UNIVERSITY OF
TORONTO**

Scarborough College

One-year visiting or limited term professorship for 1978/79.

Duties, teaching and research in mathematics. Salary and rank according to qualifications and experience. Send curriculum vitae, and have three letters of reference sent to:

Professor John E. Dove
Chairman
Physical Sciences Division
Scarborough College
University of Toronto
West Hill, Ontario M1C 1A4
Canada 1498(A)

**THE UNIVERSITY
COLLEGE OF WALES
ABERYSTWYTH**

**DEPARTMENT OF BOTANY
AND MICROBIOLOGY**

Applications are invited for the post of Lecturer in Botany. Candidates should have a special interest in an applied aspect of plant ecology e.g. conservation, land use planning or landscaping.

Salary scale: £3,333 to £6,655 p.a. (under review).

Application forms and further particulars available from the Registrar, Old College, King Street, Aberystwyth to whom applications should be sent by March 10, 1978. 1499(A)

**UNIVERSITY OF
EDINBURGH
DEPARTMENT OF
PATHOLOGY**

RESEARCH FELLOW

Applications are invited for the post of Research Fellow to work on a project concerning cells in the allergic response. The successful applicant would probably have experience in biochemistry or pharmacology or immunology. A Ph.D. or equivalent is preferable. The project is supported by the Medical Research Council for a period of three years commencing as soon as possible. The salary will be on Research Range 1A with superannuation.

Applications, including the names of two referees, should be sent as soon as possible to Dr A. B. Kay, Department of Pathology, Medical School, Teviot Place, Edinburgh, from whom further details may also be obtained. Please quote reference 5033. 1527(A)

**MEDICAL
RESEARCH COUNCIL
NATIONAL INSTITUTE
FOR MEDICAL RESEARCH
A POSTDOCTORAL
SCIENTIST**

is required to work on applications of a newly developed technique for separation of cells and macromolecules, using two phase aqueous polymer systems. The candidate will be working in co-operation with engineers and biochemists, and would have a primary responsibility for developments in the biochemical and cell biology side of the project. This is an opportunity for stimulating interdisciplinary research, in which the ability to work and communicate with others is essential.

The appointment will be for up to three years and will be in the present salary range £3,995 to £5,219 p.a. according to age and qualifications plus £450 p.a. London Allowance; superannuation provision.

Applications, giving details of qualifications, experience and the names of two professional referees, should be sent to the Director, National Institute for Medical Research, Mill Hill, London NW7 1AA. 1561(A)

**THE MEDICAL
RESEARCH COUNCIL
DEVELOPMENTAL
NEUROBIOLOGY UNIT
has a vacancy for a
BIOCHEMIST or
CELL BIOLOGIST**

with postdoctoral experience, to join a multidisciplinary research team. The work concerns the isolation and characterisation of cell types from the mammalian brain. Previous experience in membrane biochemistry, protein chemistry or immunology, with an interest in tissue culture, is of advantage. The position (M.R.C. non-clinical staff) is for a year with a possible extension for a period not exceeding three years.

Applicants should send a curriculum vitae giving full details of qualifications and experience and the names of three referees to Dr R. Balazs, M.R.C. Developmental Neurobiology Unit, Institute of Neurology, 33 John's Mews, London WC1N 2NS. 1482(A)

**UNIVERSITY OF IBADAN—
NIGERIA**

Applications are invited for

LECTURESHIP

IN DEPARTMENT OF HUMAN
NUTRITION

Candidates must have a doctorate. This post will specifically be used to encourage studies of energy use and basal metabolic studies in humans. The Department has plans to carry out studies in this field as well as the teaching of undergraduate and post-graduate students. Preference will be given to candidates with expertise in this special field, though candidates with expertise in other fields of human nutrition will also be considered.

Salary scale: N5,460 to N6,984 p.a. (£4,333 to £5,542 p.a. sterling) (£1 sterling=N1.26). There will not be provision of salary supplementation or associated benefits, 25% of salary contract addition (partly taxable) is payable. Family passages; various allowances; superannuation scheme; biennial overseas leave.

Detailed application (2 copies) including a curriculum vitae and naming 3 referees, should be sent by air mail, not later than March 22, 1978, to the Registrar, University of Ibadan, Ibadan, Nigeria.

Applicants resident in U.K. should also send 1 copy to the Inter-University, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address. 1549(A)

THE ROYAL SOCIETY

The Royal Society requires

SCIENCE GRADUATE

(up to 30) to assist in its editorial department. General aptitude for scientific editorial work required; some knowledge of mathematics essential and of biological nomenclature desirable.

Progressive salary scale and superannuation scheme. Commencing salary up to £4,200 depending on age and experience.

Applications with names, etc., of two referees to the Executive Secretary, 6 Carlton House Terrace, London SW1Y 5AG, by March 9, marking the envelope 'Personal; W.G.E.'. 1556(A)

**THE
MACAULAY INSTITUTE
FOR SOIL RESEARCH**

DEPARTMENT OF

SOIL FERTILITY

Applications are invited for a

**SCIENTIFIC OFFICER/
HIGHER SCIENTIFIC
OFFICER**

to develop electrochemical studies on nutrient relationships in soils. Candidates should have a First or Upper Second Class Honours Degree, or a Higher Degree or equivalent, in Chemistry, and should be familiar with, and preferably have research experience of, recent developments in electro-analytical techniques and instrumentation. At least two years' relevant postgraduate experience required for appointment as Higher Scientific Officer.

Salary £2,592 to £4,032 (Scientific Officer) or £3,745 to £4,976 (Higher Scientific Officer) per annum including current supplements, according to qualifications and experience. Non-contributory superannuation scheme operative.

Forms of application and further information may be obtained from The Secretary, The Macaulay Institute for Soil Research, Craigiebuckler, Aberdeen AB9 2QJ, to whom they should be returned by 17 March 1978. Quote Ref. 78/3. 1553(A)

**Biochemical Pharmacologist
(£8,000 to £12,000 p.a.)**

A biochemist with considerable theoretical and practical experience in drug metabolism and pharmacokinetics is required to develop and supervise a number of experimental drug studies. Applicants should have at least 3-5 years of postdoctoral experience and would be expected to design and supervise experimental work within the Institute, coordinate external contract studies and be responsible for the final collation and interpretation of results. The International Pharmaceutical Research Institute is located near Munich, has modern research facilities and spoken German is *not* essential. Applicants should hold a passport from an EEC country and would be paid according to age and experience but the salary would be in the range £8,000-£12,000. Applications together with supporting material to Professor C. Kozma, IPHAR, D 8012, Munchen-Ottobrun, Pestalozzistr 25, West Germany. 1557(A)

UNIVERSITY OF EDINBURGH CHAIR OF MATHEMATICS

Applications are invited for the Chair of Mathematics in the University of Edinburgh, left vacant by the recent death of Professor Arthur Erdelyi, F.R.S. The position can be taken up as soon as is convenient to the successful applicant.

As both Pure and Applied Mathematics are represented by the present professors, no particular subject area is prescribed.

Salary within the professorial range, with U.S.S./F.S.S.U.

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh EH8 9YL with whom applications (12 copies, except for overseas candidates who need submit only one copy), giving the names of three referees, should be lodged by April 15 if possible. Please quote Reference 2/78. 1496(A)

THE QUEEN'S UNIVERSITY OF BELFAST RESEARCH ASSISTANTS DEPARTMENT OF PHYSIOLOGY

Two Research Assistantships are available in the Department of Physiology. The successful applicants will be graduates, preferably holding a first or second class Honours B.Sc. degree. Appointment is tenable initially for one year and may be renewed annually for a further five years.

Salary scale (under review): £2,904 to £4,190, initial placing dependent upon age and qualifications.

Applications giving a full curriculum vitae and the names and addresses of two referees should be addressed to the Personnel Officer, The Queen's University of Belfast BT7 INN, Northern Ireland. Closing date: March 22, 1978. (Please quote Ref. 78/N). 1525(A)

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PHARMACOLOGY

Applications are invited for an office of:

UNIVERSITY LECTURER IN THE DEPARTMENT OF PHARMACOLOGY

The initial appointment will be for three years from October 1, 1978, with the possibility of re-appointment to the retiring age.

The pensionable stipend for a University Lecturer is on scale £4,607 to £7,087 a year, with initial placing above the minimum where appropriate. There is no grade of Senior Lecturer. A grant is made towards removal expenses.

Candidates should send twelve copies of their application together with the names of not more than three referees to Mr G. R. Anderson, General Board Office, The Old Schools, Cambridge CB2 1TT, from whom further particulars can be obtained, to arrive not later than March 20, 1978. 1417(A)

Product Registration Pharmacist

We are an international pharmaceutical company with European Headquarters in Paris. We are seeking a qualified pharmacist who has an interest in regulatory affairs and who would be responsible, in due course, for the registration of our proprietary products in the U.K., Eire, Scandinavia and english-speaking Africa.

The job can be based in the U.K. or in Paris, but knowledge of French is not essential.

If you:

- are a qualified British pharmacist with at least three years' post-graduate experience, and, preferably, a post-graduate qualification,
- have an interest in the registration of the proprietary products of a successful, expanding international pharmaceutical company,
- are willing to travel extensively between the U.K., Paris and Scandinavia,

then please send a resumé of your career and salary history to:

Mr. R. K. Bryant, Richardson-Merrell Ltd.,
20 Queensmere, Slough, Berkshire SL1 1YY.

1570(A)

UNIVERSITY OF OXFORD

Sir William Dunn
School of Pathology

The University proposes to appoint a
LECTURER

in the Sir William Dunn School of Pathology who will be required to provide teaching in a course for medical students on the principles of cellular pathology and bacteriology and to provide advanced teaching in either cell biology or immunology.

Salary according to age on the scale £3,333 to £7,087 per annum with superannuation.

The post may be held in association with a tutorial fellowship at Wadham College.

Further enquiries concerning both the lectureship and the fellowship should be addressed to Professor H. Harris, F.R.S., Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE, to whom applications (8 copies; one in the case of overseas candidates), together with the names of three referees should be sent by 31 March 1978. 1545(A)

The Polytechnic of North London Physics Department Research Fellow

There is a vacancy for work on low background counting with particular application to measurements of the environmental background of neutrons and to the development of a high efficiency neutron multiplicity detector.

Candidates should have a Ph.D. in experimental physics, preferably with experience in nucleonics, or an equivalent industrial research background.

Fellowships are renewable annually and may be extended up to two or three years. The salary scale is £3,822 to £4,239 (inclusive of London Allowance) with the initial placing depending on previous experience.

Applications giving brief details of experience and qualifications, and requests for further information, should be made to the Head of the Physics Department, The Polytechnic of North London, Holloway, London N7 8DB, as soon as possible. 1489(A)

directeur adjoint de la recherche

160 000 F +

NOUS SOMMES un Centre de Recherche Pharmaceutique Interdisciplinaire - 50 personnes. Nous collaborons avec plusieurs équipes hospitalières ou universitaires tant en France qu'à l'étranger. Nous disposons d'un équipement de pointe et avons élaboré et appliqué avec succès un MODELE NOUVEAU de recherche. Notre Directeur de la Recherche et du Développement crée un poste de DIRECTEUR ADJOINT DE LA RECHERCHE.

SA MISSION sera de coordonner et d'animer une équipe de chercheurs en proposant des méthodologies propres à développer la créativité de chacun, de faire la synthèse des efforts des spécialistes de chaque discipline afin de faire converger les recherches vers la création thérapeutique.

IL FAUT :

- avoir un haut niveau de culture scientifique générale,
- maîtriser les techniques de recherche biologique - biochimie et pharmacologie -
- avoir si possible une expérience post-doctorale de pharmacologie expérimentale,
- parler et lire couramment l'anglais.

LE POSTE convient à un excellent concepteur, de forte ambition scientifique, doué d'enthousiasme et de qualités relationnelles, souhaitant s'épanouir dans l'application de la recherche fondamentale à des fins de réalisation thérapeutique.

Le poste pourra comporter quelques missions à l'étranger.

LIEU DE RESIDENCE région agréable à 200 km de PARIS.

Adresser une lettre manuscrite, ainsi que votre dossier à Madame EDELMAN, qui assurera les premiers contacts dans un souci absolu de discrétion.

CNPG 105, avenue Victor Hugo - 75116 Paris

1543(A)

Geneva Research Centre

seeks

for its Group of Biochemical and Biomedical Research

—an **EXPERIMENTAL PATHOLOGIST** or **TOXICOLOGIST** to develop new areas of research while devoting a portion of his time to the histopathological evaluation of toxicity studies.

—a **PHYSIOLOGIST** with experience in respiratory physiology to participate in an expanding programme in inhalation toxicology.

Knowledge of French would be an asset.

Please address full particulars, with curriculum vitae, photograph and salary requirements to the Personnel Manager, Battelle, 7 route de Drize, 1227 Carouge-Geneva, Switzerland.

1522(A)

THE
ROYAL INSTITUTION
OF GREAT BRITAIN
WOLFSON
PROFESSOR OF
NATURAL
PHILOSOPHY

The Managers of the Royal Institution intend to make an appointment to this newly endowed full-time Chair. Scientists active in physical or biological research, who are also interested in the work of the Royal Institution, are invited to seek further information, from Sir George Porter, Director, The Royal Institution, 21 Albemarle Street, London W1X 4BS.

1554(A)

UNIVERSITY OF
LEICESTER
CHAIR OF
APPLIED PHYSIOLOGY

Applications are invited for a Chair of Applied Physiology within the Department of Physiology, tenable from October 1, 1978 or as soon as possible thereafter. The primary responsibility of the post will be the teaching of medical students and previous experience is essential. There are excellent facilities for research. A medical qualification is desirable but not obligatory. In an appropriate case the Professor would have an Honorary Consultant contract in the N.H.S.

Further particulars may be obtained from the Registrar, The University, Leicester, LE1 7RH, to whom applications (15 copies) should be sent by March 31, 1978 quoting reference NCAP.

1500(A)

VICTORIAN COLLEGE OF PHARMACY LTD.
Melbourne Australia

Position of Dean (Principal) of the College
\$30,786 (Australian)

The Council of the College invites applications for the position of Dean of the College from January 1, 1979, when Dean Nigel C. Manning, C.B.E., retires.

The position is that of the chief executive of the College, and the successful applicant will have enjoyed a broad scientific academic background, preferably in the pharmaceutical sciences, and will have extensive academic and administrative experience.

The occupant will receive a professional salary and an additional allowance of \$4,000 per annum.

Further information on the position may be obtained from the Registrar of the College, with whom applications and the names of three referees should be lodged at 381 Royal Parade, Parkville, Victoria, Australia 3052. The closing date for receipt of applications is April 14, 1978.

Council reserves the right to appoint by invitation.

1146(A)

UNIVERSITY OF WINDSOR
DEPARTMENT OF CHEMISTRY
APPOINTMENT OF
ASSISTANT PROFESSOR

The Department of Chemistry at the University of Windsor expects to have a vacancy for an Assistant Professor, available on July 1, 1978. Applicants should have a Ph.D. preferably in biochemistry and the position will involve teaching in the undergraduate and graduate programs as well as independent research in biochemistry. The Department is well equipped with modern instrumentation and offers a Ph.D. program in biochemistry. Preference will be given to applicants with research experience in metabolism, the biochemistry chemistry of disease, membrane biochemistry or molecular enzymology.

A curriculum vitae with research interests and the names of three referees should be submitted to:

Professor J. E. Drake,
Department of Chemistry,
University of Windsor,
Windsor, Ontario N9B 3P4,
1522(A)

UNIVERSITY OF READING
DEPARTMENT
OF MICROBIOLOGY
RESEARCH FELLOW

required immediately until 14 April 1980 to work on an A.E.R.E. Harwell funded project to identify and quantify microbiological processes occurring in the degradation of domestic and industrial wastes in landfill. Postdoctoral applicants will be given preference but those with equivalent research experience will be considered. The relevant areas of study are microbial ecology and physiology, including fermentation. The work will be closely associated with field and laboratory studies in controlled landfill experiments which are run from Harwell Laboratory by a team of hydrogeologists, chemists and microbiologists for both Department of Environment and Industry.

Starting salary in range £3,333 to £4,190 p.a. (under review) plus U.S.S. superannuation.

Apply for further particulars quoting Ref. M.N.13A, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH,
1568(A)

AQUACULTURE
POSITIONS

University of California, Davis

Faculty positions in a developing aquaculture program. Appointments in the Department of Animal Science, positions housed at Bodega Marine Laboratory. Experience or a strong interest in research and teaching related to the development of aquaculture is essential. **INVERTEBRATE PHYSIOLOGY:** Assistant Professor, 20% teaching and 80% research; supervise a marine program. Ph.D. in an appropriate discipline and expertise in larval physiology, endocrinology or behavioral physiology of marine invertebrates. Teaching at both undergraduate and graduate levels expected. **PATHOLOGY:** Research position, assistant or associate level and lecturer. Ph.D. in fish or invertebrate pathology and interest in research in marine, aquatic-animal pathology and providing diagnosis and treatment for other aquaculture units. Supervision of graduate students expected.

Applicants should submit résumé, letter describing qualifications, publication list, three letters of reference and copies of transcripts to: WALLIS H. CLARK, JR., DIRECTOR OF AQUACULTURE, DEAN'S OFFICE, COLLEGE OF AGRICULTURAL AND ENVIRONMENTAL SCIENCES, UNIVERSITY OF CALIFORNIA, DAVIS, CA 95616 prior to April 15, 1978. Position available July 1, 1978.

The University of California is an Equal Opportunity/Affirmative Action Employer.
1481(A)

MINISTRY OF
OVERSEAS DEVELOPMENT
TROPICAL PRODUCTS
INSTITUTE
BIOCHEMIST/FOOD
SCIENTIST

The above Institute which carries out research to aid developing countries invites applications for a Scientific Officer to work in its New Food Products Section. The work will involve the development of acceptable foods for developing countries, the study of food enzymes in the laboratory, and the analysis of tropical fruits, vegetables and other types of produce. Applicants should have a degree in biochemistry or food science together with broad interests in all aspects of food processing. This post will be a period appointment of two years. Other conditions of service are: Salary £2,614 to £3,992 plus the Government supplements to pay up to a maximum of £522 per annum; 5-day of 41 hours (including lunch breaks); 20 days leave a year; the post is also pensionable.

Application forms from Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB.
1486(A)

ASSISTANT OR
ASSOCIATE PROFESSOR
ANIMAL PHYSIOLOGY at
CORNELL UNIVERSITY
Division of Biological Sciences

Teach, coordinate senior/graduate course in mammalian physiology, including extensive laboratory section. Candidate should have good background in modern and classical techniques in vertebrate organ physiology. Ph.D., M.D., D.V.M. or equivalent required, with postdoctoral experience desirable. Preference given to applicants with teaching and research expertise in endocrine, skeletal, cardiovascular, respiratory, or renal physiology.

Send curriculum vitae and three letters of recommendation by April 7, 1978 to: Dr R. H. Wasserman, Room 717 Veterinary Research Tower, N.Y.S. College of Veterinary Medicine, Cornell University, Ithaca, N.Y. 14853. An Affirmative Action/Equal Opportunity Employer. Applications from women and minorities are encouraged.
1502(A)

UNIVERSITY OF THE
WEST INDIES—BARBADOS

Applications are invited for the post of **SENIOR LECTURER/LECTURER IN THE DEPARTMENT OF PHYSICS**. Duties to be assumed by September 1, 1978 or as soon as possible thereafter. Salary scales: Senior Lecturer: BDS\$25,827 to 34,017 p.a.; Lecturer: BDS\$19,071 to 29,799 p.a. (£1 sterling=BDS\$3.87). F.S.S.U. Unfurnished accommodation will be let by the University at a rental of 10% of salary. A housing allowance of 20% of salary is payable to staff who make their own housing arrangements. Family passages. Study and Travel Grant.

Detailed applications (three copies) giving full particulars of qualifications and experience, date of birth, marital status and names and addresses of three referees should be sent as soon as possible to the SECRETARY, UNIVERSITY OF THE WEST INDIES, P.O. BOX 64, BRIDGETOWN, BARBADOS. The University will send further particulars for this post to all applicants. These particulars may also be obtained from the Inter-University Council for Higher Education Overseas, 90-91 Tottenham Court Road, London W1P 0DT.

1517(A)

UNIVERSITY OF
SASKATCHEWANSaskatoon, Saskatchewan,
CanadaApplications are invited for the
following positions in the Department
of Crop Science.1. PROFESSIONAL
RESEARCH ASSOCIATEA plant physiologist with training
and experience in the area of water
relations and/or stress physiology.

The successful applicant will be one
of a team of two other scientists and
three technicians who are undertaking
a comprehensive analysis of the role
of plant hormones in drought stress
in sorghum. The study, supported by
the International Development
Research Centre, Ottawa, is designed
to provide cereal scientists working in
the semiarid tropics with a more com-
plete knowledge of the manner in
which plant growth and productivity
are influenced by drought stress. The
project is currently in its third year
and will continue for a minimum of
1.5 years with an anticipated extension
of two further years.

The commencing salary will be
\$16,498 which includes a pension and
other benefits equivalent to 7.9% of
salary. Annual increments in salary
will be in accordance with University
of Saskatchewan increments. Minimum
qualification is a Ph.D. and the
appointee will be expected to join
the group by April 15, 1978. Applica-
tions, which close February 24, should
include curriculum vitae, transcripts
of marks and three letters of reference.

2. PROFESSIONAL
RESEARCH ASSOCIATE

Applications are invited for the
following position as a member of a
multi-disciplinary project on the
biology of wild oats (*Avena fatua*).
A plant physiologist with experience
in the field of seed physiology. Several
years postdoctoral research experience
in the areas of biochemistry and regu-
lation of germination and dormancy is
desirable. The successful applicant will
be expected to direct a full-time tech-
nician and undertake a study of both
the physiological basis of temperature
dependence of seed dormancy and
regulation of endosperm function. The
appointee is expected to interact with
two geneticists, two physiologists and
a herbicide specialist also working
on the project.

The commencing salary will be
\$16,498 which includes a pension and
other benefits. Annual increments will
be in accordance with University of
Saskatchewan increments.

Application which closes on March
15 should include curriculum vitae,
transcripts of marks and three letters
of reference sent to:

Professor G. M. Simpson
Crop Science Department
University of Saskatchewan
Saskatoon, Saskatchewan
Canada S7N 0W0.

1503(A)

SUPERVISOR
RADIOIMMUNOASSAY
FACILITIES

The Department of Obstetrics and
Gynaecology at McGill University has
an immediate opening for a person
experienced in the development, vali-
dation, performance and quality con-
trol of radioimmunoassays for both
steroid and peptide/protein hormones.
Applicants should have a minimum of
a M.Sc. degree (or equivalent), be pre-
pared to work in an academic research
environment and have experience in
the supervision of technicians. Remu-
neration will be commensurate with
professional experience. Please send
curriculum vitae and names and
addresses of three references before
March 15, 1978 to: F. Naftolin, MD,
D.Phil., Professor and Chairman,
Department of Obstetric and Gynaecology,
Women's Pavilion, Royal Victoria
Hospital, McGill University, 687
Pine Avenue West, Montreal H3A
1A1, Canada. An equal opportunities
employer.

1534(A)

UNIVERSITY OF THE
WEST INDIES—JAMAICAApplications are invited for the
following posts:DEPARTMENT OF
MICROBIOLOGY

PROFESSOR. The appointee, will
be expected to give leadership in the
teaching and research activities of the
Department of Microbiology which
prepares students for the M.B., B.S.,
degree of the University of the West
Indies. Experience in Clinical Micro-
biology would be an advantage.

SENIOR LECTURER/LECTURER.
Duties will include routine clinical
Microbiology work for the University
Hospital and instruction in Micro-
biology to students working for the
medical degree of the University of
the West Indies. Preference will be
given to medically qualified applicants.
Duties to be assumed as soon as
possible.

DEPARTMENT OF
BIOCHEMISTRY
(HUMAN NUTRITION)

**LECTURER/ASSISTANT LEC-
TURER.** The appointee is expected
to teach students for the M.Sc.
(Nutrition) degree. He/she should
have a postgraduate degree in bio-
chemistry with special reference to
human nutrition and should have
some knowledge and experience of
nutritional problems in developing
countries. He/she should also have
experience in post-graduate teaching
of human nutrition and should show
evidence of research in nutrition-
related topics. Duties to be assumed
as soon as possible.

Salary scales: Professor-Medical
J\$19,326 to J\$22,578 p.a., Non-
Medical J\$17,166 to J\$21,252 p.a.;
Senior Lecturer-Medical J\$15,339 to
J\$19,326 p.a., Non-Medical J\$12,066
to J\$16,783 p.a.; Lecturer Medical
J\$11,262 to J\$15,015 p.a., Non-
Medical J\$8,913 to J\$13,917 p.a.
Asst. Lecturer Medical J\$9,102 to
J\$9,936 p.a., Non-Medical J\$7,236 to
J\$7,926 p.a.. (£1 sterling equals
J\$2.43). F.S.S.U. Unfurnished accom-
modation will be let by the Univer-
sity at a rental of 10 per cent of
salary, or a housing allowance of
20 per cent of salary is payable.
Study and Travel Grant. Family
passages: baggage allowance. Detailed
applications (three copies) with
curriculum vitae and naming three
referees should be sent as soon as
possible to the Registrar, University
of the West Indies, Mona, Kingston
7, Jamaica. Further particulars of the
post are available from the same
source or from the Inter-University
Council for Higher Education Over-
seas, 90-91 Tottenham Court Road,
London W1P 0DT. 1518(A)

UNIVERSITY COLLEGE
HOSPITAL MEDICAL
SCHOOLDEPARTMENT OF CLINICAL
PHARMACOLOGYLaboratory of Toxicology and
PharmacokineticsRESEARCH WORKER IN
PHARMACOKINETICS

A position, probably at postdoctoral
level, is vacant in a small active team
working on problems of drug metabo-
lism and toxicity. The applicant
should have experience with H.P.L.C.
or G.C. techniques, and be interested
in research relating plasma levels of
drugs and metabolites to drug action.

Starting salary in the range of
£3,500 to £4,200, depending on qual-
ifications and experience. The appoint-
ment is for three years.

Applicants should apply in writing,
enclosing a curriculum vitae and
names of two referees, to:

Dr A. McLean,
University College Hospital
Medical School,
University Street,
London WC1

1539(A)

CSIRO
AUSTRALIAPostdoctoral
Research Fellow
Molecular and Cellular Biology Unit
North Ryde, N.S.W.

CSIRO has a broad charter for research into primary and
secondary industry areas. The Organization has approximately
7,000 employees—2,300 of whom are research and pro-
fessional scientists—located in Divisions and Sections
throughout Australia.

General: The newly established Unit forms, with part of the
Division of Animal Production, the CSIRO Genetics Research
Laboratories. Its objective is the study of basic mechanisms of
Molecular Genetics and Cellular Biology and their applica-
tions to problems of human welfare, animal production and
industry. The Unit has ten research scientists with some 21
support staff and 15 site service staff. The Unit is well equipped
for its present activities in Molecular Biology and has facilities
for small animal research. It has close working relations with
other Divisions of Applied Organic Chemistry, Food Research,
Protein Chemistry and Animal Production; the Universities of
New South Wales, Macquarie and the Australian National
University, Canberra. The laboratory is situated in a pleasant
suburban location close by other CSIRO establishments and
Macquarie University.

Duties: To work on the chemistry of mutagenesis, or DNA
breakage and repair, or the isolation, characterization and
sequencing of DNA/RNA associated with the differentiation
and evolution projects of the Unit. The Fellow would be
expected to collaborate with one of the existing groups in the
Unit which are studying DNA breakage and repair, cellular
differentiation, molecular evolution of influenza virus and
antigenic diversity. Experience with the enzymology of DNA
replication or degradation, of recombinant DNA technology
or of nucleic acid sequencing, or in some similar area would
be an advantage.

Salary: Research Scientist or Senior Research Scientist:
A\$14,506 to A\$21,134 p.a., (UK £8,703 to UK £12,680),
(US \$16,536 to US \$24,092).

Tenure: The appointment will be for a fixed term of 3-5 years.

Applications (in duplicate), stating *FULL* personal and
professional details, the names and addresses of at least two
professional referees, and quoting reference number 690/15
should reach:—The Personnel Officer, Australian Scientific
Liaison Office, Canberra House, Maltravers Street, LONDON
WC2R 3EH by 22nd March 1978.

Applications in U.S.A. and Canada should be sent to:—
The Counsellor (Scientific), Embassy of Australia, 1601
Massachusetts Avenue, N.W. WASHINGTON D.C. 20036
U.S.A. 1512(A)

nature

Nature is considering employing a physical scientist
to assist Dr Stuart Sharrock, the Physical Sciences
Editor. Such a person would have recently received a
Ph.D. and would be hoping to develop a much broader
appreciation of science. He or she would be expected to
help Dr Sharrock in the assessment of manuscripts,
work with other members of the *Nature* staff in com-
piling the various sections of the journal, establish
contacts in the scientific community and, on occasions,
write short pieces on recent scientific developments.

Write to Editor, *Nature*, 4 Little Essex Street, London
WC2 enclosing a c.v. and any other material you
consider relevant. 1430(A)

CHEMICAL ENGINEER

Challenging Experimental and Design Work

This post, based at Culham, Oxon, covers a wide spectrum of project work in relation to the processing of plant and animal produce. The main emphasis is on dehydration studies undertaken by an interdisciplinary team.

Developed processes are field tested overseas and short visits will be made to commission equipment and supervise field trials.

Candidates normally under 30 must have a degree or equivalent in Chemical Engineering. Some relevant post-graduate experience is essential.

Starting salary, as Higher Scientific Officer, will be within the range £3740—£4975.

For further details and application form (to be returned by 17 March 1978) please write to Miss C A Hall, Tropical Products Institute, 127 Clerkenwell Road, London, EC1R 5DB. Please quote ref: SA/78/JD. 1484(A)

Ministry of Overseas Development Tropical Products Institute

UNIVERSITY OF BATH LECTURERS IN PHARMACOLOGY

Applications are invited for two posts in the School of Pharmacy and Pharmacology. One of the posts is temporary for a period of two years.

Further particulars are available from the Personnel Officer, University of Bath BA2 7AY, quoting reference number 78/38N. Closing date for applications March 13, 1978. 1487(A)

UNIVERSITY OF THE WITWATERSRAND Johannesburg DEPARTMENT OF GEOLOGY CHAIR OF MINERAL GEOCHEMISTRY

Applications are invited for appointment to the above teaching and research position. Applicants should have an extensive research interest in the application of analytical or experimental mineral chemistry and/or thermodynamics to petrogenetic problems. The successful candidate will be responsible for the co-ordination and advancement of teaching-courses in geochemistry in the department; and, in addition to pursuing his own research projects, will be encouraged to participate in co-operative research programmes in a wide range of interdisciplinary Earth Science projects. A modern ARL SEMQ electron microscope has recently been installed, and a supporting post of electron microprobe operator has been advertised.

The starting salary will be determined according to qualifications and experience in the range R10,800 to R13,800 per annum (plus a 10% pensionable allowance).

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further particulars relating to this practice are included in an information sheet obtainable from the London Representative, University of the Witwatersrand, 278 High Holborn, London WC1V 7HE, or from the Registrar, University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, South Africa, 2001, with whom applications should be lodged not later than 17 March 1978. 1563(A)

UNIVERSITY OF OXFORD RESEARCH ASSISTANT

required for three years to work on aspects of muscle metabolism after severe injury. Experience in using an amino acid analyser desirable.

Pay and conditions of service on Whitley Council Biochemist Scale, from £3,560 p.a.

Applications and further information from Dr R. Smith, Tayfield Orthopaedic Centre, Headington, Oxford, or Dr D. H. Williamson, Metabolic Research Laboratory, Nuffield Department of Clinical Medicine, Radcliffe Infirmary, Oxford. 1558(A)

UNIVERSITY OF SURREY DEPARTMENT OF BIOCHEMISTRY EXPERIMENTAL OFFICER

Applications are invited for the post of Experimental Officer in the Department of Biochemistry, to work with the Head of Department, Professor D. V. Parke. The person appointed (male or female) will assist in the development of research services in the Department and carry out research work in the following areas:

metabolism and pharmacokinetics of drugs and environmental chemicals, mechanisms of drug and chemical toxicity, mechanisms of carcinogenesis, regulation of glycoprotein synthesis.

Applicants must be graduates, preferably with a higher degree in biochemistry or pharmacology and experience in biochemical and pharmacological techniques. Industrial experience would be considered an advantage.

Salary will be within the Experimental Officer range £3,975 to £5,015 per annum depending on experience and qualifications.

Applications in the form of a curriculum vitae, giving full details of age, experience and qualifications (and the names and addresses of two referees), should be sent to the Assistant Secretary (Personnel), University of Surrey, Guildford, Surrey GU2 5XH, by: March 16, 1978, and from whom further particulars of the post can be obtained: Telephone Guildford 71281, Ext. 452. 1506(A)

UNIVERSITY OF READING DEPARTMENT OF AGRICULTURAL BOTANY RESEARCH DEMONSTRATOR

required as soon as possible. Duties will include up to 12 hours per week demonstrating in practical classes related to the degree in Agricultural Botany. Candidates should have a good honours degree in Agricultural Botany, Botany or Biology, and will be expected to register for a higher degree, M.Phil. or Ph.D. Three-year appointment.

Salary in scale £2,550 to £2,750 p.a.

Applications, together with the names of two referees, should be made to Professor Watkin Williams, Department of Agricultural Botany, University of Reading, Whiteknights, Reading RG6 2AS, from whom further particulars may be obtained. Closing date: 14 March 1978. (Ref. T.N.14A.) 1569(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND FACULTY POSITION Ph.D. FOOD SCIENTIST, TEACHING AND RESEARCH

The Department of Biochemistry, Memorial University of Newfoundland is seeking an individual for teaching and research with a new undergraduate and graduate program of Food and Nutrition. Applicants should have a demonstrated ability for research in Food Science. An interest in fish and other marine sources of food is highly desirable. Date of availability on or before September, 1978. Résumé should include biography, transcripts and names of references. Respond to Dr Norman F. Haard, Department of Biochemistry, Memorial University of Newfoundland, St John's, Newfoundland, Canada A1B 3X9. 1541(A)

RESEARCH TECHNICIAN

for biochemical laboratory working on biosynthesis and intracellular transport of proteins. Applicants should have a good technical background in general biochemistry.

Salary on Whitley Technicians' scale.

Apply in writing to Mr C. G. Keast, University College Hospital Medical School, University Street, London WC1, including a curriculum vitae and names of two referees. 1551(A)

UNIVERSITY OF READING DEPARTMENT OF GEOLOGY RESEARCH DEMONSTRATOR IN GEOLOGY

required to assist with undergraduate laboratory and field classes; should have special interests in the petrology and geochemistry of crystalline rocks. Research for a higher degree will be on mineral deposition from high temperature volcanic fluids. Post available now but persons expected to graduate in summer 1978 eligible to apply. Appointment for one year in first instance, renewable. Salary in scale £2,550 to £2,750 p.a.

Further particulars from Professor P. Allen, F.R.S., Department of Geology, University of Reading, Whiteknights, Reading RG6 2AB. Closing date for applications March 13, 1978. (Ref. T.N.13A.) 1504(A)

RESEARCH ASSOCIATE POSITIONS

at the Lady Davis Institute, Montreal, will be available July, 1978 for molecular biologists to join group investigating legume gene activity during symbiotic nitrogen fixation.

Salary \$11,000 to \$13,000 per annum.

Applicants with expertise in mRNA isolation, cDNA synthesis and characterisation or restriction endonuclease mapping should contact Dr H. M. Schulman, John Innes Institute, Norwich, England. 1477(A)

EUROPEAN TISSUE CULTURE SOCIETY— GLASGOW

July 3–5, 1978

Main topics—differentiation in Friend cells and teratocarcinoma, somatic cell genetics, characterisation of tumour cells *in vitro*, plus workshops and poster sessions on a wide range of topics related to tissue culture.

Enquiries to Doctor Ian Freshney, Beatson Institute for Cancer Research, Gartcube Estate, Bearsden Road, Glasgow G61. 1510(C)

UNIVERSITY OF CALGARY DEPARTMENT OF PHYSICS

RESEARCH ASSISTANT required to carry out observational and experimental work related to the LOWER ATMOSPHERE. The successful candidate should either have experience or an interest in one of the following: aerosol science, atmospheric visibility, urban pollution, lidar probing or atmospheric optics; and must be able to handle associated equipment both in the laboratory and in the field. This position provides an excellent opportunity to gain experience in environmental physics in association with a relatively small and friendly group of scientists, technicians, and graduate students. B.Sc. and Ph.D. graduates may apply. Aptitude for experimental work and relevant experience considered as important as basic qualification.

Salary range, \$9,600 to \$14,400.

Apply to Professor A. W. Harrison, Department of Physics, University of Calgary, Alberta, Canada, including a brief résumé of background and experience.

UNIVERSITY OF SASKATCHEWAN COLLEGE OF DENTISTRY SASKATOON, CANADA ORAL BIOLOGY

Applications are invited for two full-time positions in the Department of Oral Biology. Depending on qualifications, applicants may be considered for Chairmanship of the Department.

ORAL PATHOLOGY: The applicant should have a dental degree and graduate training in Pathology—Oral and/or General. Responsibilities will include teaching at the undergraduate level, research and managing a diagnostic histopathology service.

ORAL BIOCHEMISTRY/MICROBIOLOGY: The applicant should have a dental degree and graduate training preferably beyond the Masters level. Responsibilities will include teaching at the undergraduate level and research in biochemistry/microbiology.

Rank and salary will be determined according to qualifications and experience.

Letters of application and curriculum vitae should be sent to: Dr E. R. Ambrose, Dean, College of Dentistry, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0 1442(A)

UNIVERSITY OF ESSEX DEPARTMENT OF BIOLOGY

The following posts, funded by a grant from the Medical Research Council to Dr R. W. Davies, are available immediately and tenable for three years.

Both are for work on the structural basis of site-specific recombination of bacteriophage lambda, using modern nucleic acid sequencing methods.

POSTDOCTORAL RESEARCH FELLOW (Ref. AG/19)

Starting salary £3,333 p.a. on Range 1A of Auxilliary (Research) Staff scale. Applicants having experience in nucleic acid biochemistry or molecular biology preferred.

RESEARCH TECHNICIAN (Ref. P36)

Starting salary £3,186 p.a. of Technician Grade 5. Applicants should have extensive research experience.

Two copies of applications (quoting the appropriate reference) including a curriculum vitae and the names and addresses of two referees, should reach the Registrar, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained by 16 March. 1567(A)

UNIVERSITY OF EDINBURGH DEPARTMENT OF GEOLOGY A RESEARCH ASSOCIATE

is required to assist in operating a Microscan 5 electron probe analytical unit, jointly supported by the Natural Environment Research Council and the University of Edinburgh. The contract will be for a period of 28 months in the first instance to start as soon as possible.

Salary will be on research range 1B or 1A, according to age and experience. The appointee will be expected to pursue his/her own and collaborative research topics; in addition he/she will be responsible for user instruction, and the coordination and supervision of an analytical service to other workers. The position will carry superannuation under normal university schemes.

Applications (2 copies) should be sent to:

Professor M. J. O'Hara
Grant Institute of Geology
West Mains Road
Edinburgh EH9 3JW
by March 15, 1978, from whom further particulars can be obtained.
Please quote: Reference 5004. 1546(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London) BIOPHYSICAL ENDOCRINOLOGY UNIT, DEPARTMENT OF PHYSICS AS APPLIED TO MEDICINE

Applications are invited for a Research Assistant 1A; starting salary, depending on age and qualifications, of £3,783 to £4,212 including £450 per annum London Allowance.

Suitable for a postdoctorate, this post will be available for two years, funded by a Medical Research Council Programme Grant. The project will involve the in vitro assay of pressor substances including the preparation and use of dispersed muscle cells. Reproduction and investigation of other biological cells may be involved.

Applications, together with the names of two referees should be sent to the Secretary, Department of Physics as Applied to Medicine, Hindey Building, Cleveland Street, London W1P 6DB. 1462(A)

UNIVERSITY OF NAIROBI KENYA

Applications are invited for the following posts:

DEPARTMENT OF CROP SCIENCE SENIOR LECTURER

Applicants should have a basic degree in Agriculture or Horticulture plus a Ph.D. in Agronomy, Agricultural Botany, Crop Physiology, Plant Breeding or Crop Protection. Experience in teaching and research is essential. The applicant should participate in teaching undergraduate and postgraduate courses and in the department's research activities.

DEPARTMENTS OF SOIL SCIENCE AND BOTANY (MIRCEN PROJECT)

SENIOR LECTURER/ LECTURER (Microbiologist)

Applicants should possess a Ph.D. in either Soil Science or Microbiology with considerable relevant university teaching and research experience in legume bacteriology. Expertise on nitrogen fixation entailing rhizobia-legume symbiosis is a desirable advantage. The appointee will be expected to teach undergraduate and postgraduate courses, conduct research on nitrogen fixation in collaboration with the University of Nairobi U.N.E.P., U.N.E.S.C.O., I.C.R.O. (MIRCEN) project. Appointment will be on contract for two years.

Salary scales: Professor K£4,632 to K£5,562 p.a.; Senior Lecturer K£2,988 to K£3,984 p.a.; Lecturer K£2,016 to K£3,312 p.a. (K£1=£1.29 sterling.) The British Government may supplement salaries in range £3,354 to £4,674 p.a. (sterling) for married appointees and £2,184 to £3,384 p.a. (sterling) for single appointees (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Terms of service include family passages: superannuation and medical aid scheme; subsidised housing and various allowances.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent to Registrar, University of Nairobi, P.O. Box 30197, Nairobi, Kenya, by March 15, 1978.

Applicants resident in U.K. should send one copy to Inter-University Council for Higher Education Overseas, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 1548(A)

MATHEMATICS GRADUATE STUDY

Graduate Assistantships paying up to \$6,000 per year plus tuition are available in the Mathematics Department, Clarkson College, Potsdam, N.Y. 13676.

Clarkson offers a well-rounded curriculum with emphasis in applied mathematics, particularly in the following fields: Matrix Methods in Systems Science, Mathematical Physics, Computer Science, Statistical Methods in Oil and Mineral Resource Prediction, Nonlinear Waves, Numerical Analysis, and Functional Analysis. For additional information write to Dean of the Graduate School, Clarkson College, Potsdam, NY 13676.

Clarkson College is an equal opportunity/affirmative action employer. X1533(A)

UNIVERSITY OF WARWICK RESEARCH FELLOW

Applications are invited for a S.R.C. postdoctoral research fellowship for two years in the Department of Physics, to work on the diffusion of hydrogen and deuterium in transition metals using pulsed field gradient nuclear magnetic resonance. Experience in N.M.R. is desirable but not essential. Initial salary will be at not higher than point 3 (£3,761 p.a.) on the Range 1A scale £3,333 to £5,627 p.a. (under review). Further particulars and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No: 28/R/78. 1513(A)

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE SENIOR PRINCIPAL SCIENTIFIC OFFICER

HEAD OF THE CHEMISTRY DIVISION

Applicants should have a broad qualification in Chemistry and distinction in a relevant research area with a biological or biochemical background since a significant element of biochemical research will be included in this Division.

Physical and biophysical interests will be the responsibility of a parallel division to be created in the near future. Experience related to the interests of the Food Industry will be of especial value. The total staff of the Division will be approximately 40, including at least six Principal Scientific Officers and support staff divided into groups broadly concerned with Lipid, Carbohydrate, Protein, Natural Product and Biochemistry in relation to food.

The Institute is housed in virtually new laboratories in Norwich and takes a major role in the ARC research effort on food in the UK. Further details are available in a document which outlines some of the proposed developments.

The salary range for this appointment is £8,858 to £10,006 per annum, including Phase II pay supplement, and there is a non-contributory superannuation scheme.

Application forms (and further particulars) are available from the Secretary, ARC Food Research Institute, Colney Lane, Norwich NR4 7UA, to whom they should be returned by 3rd April 1978. 1519(A)

POSTDOCTORAL IMMUNOBIOLOGIST

required to join research team concerned with the control of IgE antibody responses.

Particular emphasis will be directed towards assessing the effects of varying antigen structure on suppressor cell activity. Applicants should have considerable experience with cellular immunological techniques.

Application forms from: Mrs Nancy Morgans, Personnel Manager, Miles Laboratories Ltd, Stoke Court, Stoke Poges SL2 4LY. Tel: Farnham Common 2151. 1524(A)

NOTE CHANGE IN PREVIOUSLY ANNOUNCED POSITION FOR VERT. PALEONTOLOGIST, UNIVERSITY OF KANSAS. The 9 mo. 1-time position in Sys. & Ecol. will be expanded to 12 mo. 1-time. The Mus. of Nat. Hist. position remains 12 mo. 1-time and the combined salaries will be 16,000-18,000. The closing date for applications will be extended to March 30, 1978. Apply: Larry Martin, 602 Dyche, Univ. of Kansas, Lawrence, KS 66045. Equal Opportunity Employer. 1535(A)

UNIVERSITY COLLEGE CORK DEPARTMENT OF ELECTRICAL ENGINEERING FULL-TIME APPOINTMENT

The Governing Body invites applications for a full-time post as Assistant Lecturer/College Lecturer in the Department of Electrical Engineering. The appointment will be made at one of the levels mentioned according to the qualifications and experience of the successful candidate.

The salary scales are:—
College Lecturer £5,115 to £6,121 to Bar to £6,141 to £7,340 p.a.
Assistant Lecturer £4,403 to £4,805 p.a.

Application form and further details of the post may be obtained from the undersigned.

Latest date for receipt of applications is Thursday, March 16, 1978.

M. F. Kelleher
Secretary

UNIVERSITY COLLEGE CORK DEPARTMENT OF STATISTICS FULL-TIME APPOINTMENT

The Governing Body invites applications for a full-time post as Assistant Lecturer/College Lecturer in the Department of Statistics. The appointment will be made at one of the levels mentioned according to the qualifications and experience of the successful candidate.

The salary scales are:—
College Lecturer £5,115 to £6,121 to Bar to £6,141 to £7,340 p.a.
Assistant Lecturer £4,403 to £4,805 p.a.

Application form and further details of the post may be obtained from the undersigned.

Latest date for receipt of applications is Thursday, March 16, 1978.

M. F. Kelleher
Secretary
1497(A)

MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE

Carshalton, Surrey

Applications are invited for the post of Senior Research Officer in the Director's Department.

The successful candidate will be expected to assist the Director with:

- (i) personal assistance with his administrative duties
- (ii) a research programme designed to evaluate specific pathogen free cats.

It is hoped that he/she will be a mature person with an interest in scientific administration. Applicants should have a degree in biological science, together with a Ph.D., and previous experience with small animals would be an advantage although not essential. The post offers excellent conditions of service. Salary in the range £3,999 to £5,199 according to age, qualifications and experience, plus £354 London Weighting, plus £312 Pay Supplement, plus Variable Pay Supplement. Contributory Superannuation Scheme.

Applications, together with a curriculum vitae and the names of two referees should be sent to the Director, Medical Research Council Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey SM5 4EF.

1377(A)

MRC

Medical Research Council

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London) DEPARTMENT OF MEDICINE RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to work on the development of Homologous Assays for Human Parathyroid Hormone. Candidates should preferably have a Ph.D. and experience with immuno-assays is desirable. The post is available for three years.

Starting salary, according to age and qualifications, up to £3,996 per annum inclusive of £450 per annum London Allowance.

Applications, including curriculum vitae and the names and addresses of two referees, should be submitted to Dr J. L. H. O'Riordan, Department of Medicine, Sir Jules Thorn Institute of Clinical Science, The Middlesex Hospital Medical School, London W1P 7PN. 1529(A)

UNIVERSITY OF OTAGO Dunedin, New Zealand DIRECTOR, ANIMAL BREEDING STATION

Applications are invited from graduates in either veterinary, biological or agricultural science with training and experience or interest in small animal husbandry to take charge of the University Animal Breeding Station and Laboratory Animal Sciences Unit of the Medical School and be consultant on housing and care of laboratory animals within the University system. The Director will be encouraged to pursue his own research interests.

Appointment carries salary and academic status of Lecturer or Senior Lecturer.

Salary: Lecturer NZ\$10,585 to \$12,969; Senior Lecturer NZ\$13,424 to \$16,546 with a bar at \$15,411 per annum.

Further particulars are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on May 15, 1978. 1540(A)

UNIVERSITY OF STIRLING DEPARTMENT OF BIOLOGY UNIT OF AQUATIC PATHOBIOLOGY

Applications are invited for a post as Lecturer in Aquaculture from June 1, 1978. The successful candidate will be required to teach in the M.Sc. and diploma courses run by the Unit and to undertake research in an appropriate field. Preference will be given to applicants who are also qualified to teach in undergraduate courses in Biology. Salary scale £3,333 to £6,655 plus F.S.S.U./U.S.S. (currently under review).

Applications, naming two referees, which should be received by March 15, 1978 by The Secretary (N), University of Stirling, Stirling FK9 4LA, from whom further information is available. 1526(A)

UNIVERSITY OF QUEENSLAND Australia

RESEARCH FELLOW Platypus Ecology Project

This project is funded by the Australian National Parks and Wildlife Service. It aims to provide information on various aspects of the ecology of the platypus (*Ornithorhynchus anatinus*), such as distribution, population dynamics, dietary requirements, environmental parameters and reproductive ecology. The successful applicant should hold (or expect to be awarded in the near future) a Ph.D. or equivalent and have experience in the conduct of field investigations. Consideration may be given to the appointment of an otherwise well qualified applicant, who does not hold a Ph.D. on the Senior Research Assistant scale. The appointment will be for one year in the first instance and the appointee should be prepared to take up his duties as soon as possible.

Closing date for application is 31 March 1978, and further information may be obtained from the Chief Investigator (F. N. Carrick), Reproductive Biology Group, Department of Veterinary Anatomy, University of Queensland, St. Lucia, Brisbane 4067, Australia. (Quote Reference No. 06578.)

Salary: \$A14,851 to \$A23,299 per annum. 1564(A)

STUDENTSHIPS

GLASSHOUSE CROPS RESEARCH INSTITUTE invites applications for an AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

tenable at the Institute for three years for studies with *Verticillium fungicola* the casual organism of dry bubble disease in cultivated mushroom.

Minimum qualification first or upper second class honours degree in relevant subject.

Application forms and further particulars available from Secretary, G.C.R.I., Worthing Road, Rustington, Littlehampton, Sussex. Closing date for applications March 20. 1509(F)

UNIVERSITY OF BRISTOL LONG ASHTON RESEARCH STATION AGRICULTURAL RESEARCH COUNCIL STUDENTSHIP

A studentship will be offered to an honours graduate (first or upper second class) in appropriate science subjects for research on one of the following topics:—

1. The effects of leaf diseases on yield potential in cereals.
2. Cytogenetic basis of fungicidal action and resistance mechanisms.
3. The biosynthesis of antifungal amine conjugates in barley.

Candidates should normally be under 27 years of age on October 1, 1978 and graduates of a British Commonwealth University, being British subjects normally resident in the United Kingdom. The successful applicant will be expected to register for a higher degree in the University of Bristol.

Application forms and further particulars can be obtained from The Secretary, Long Ashton Research Station, Long Ashton, Bristol BS18 9AF. The closing date for receipt of completed application forms is March 17, 1978. 1520(F)

SCOTTISH HORTICULTURAL RESEARCH INSTITUTE Invergowrie, Dundee DD2 5DA Agricultural Research Council

POSTGRADUATE STUDENTSHIP

Applications are invited for a Studentship tenable for 3 years from October 1978 in the Virology Section of the Institute. Research will centre on the properties of viruses infecting carrot, parsnip and other umbelliferous plants, and the way in which the viruses are transmitted by aphids. A background of plant pathology, cell biology or entomology is desirable.

The minimum qualification is an Upper Second Class Honours degree. Students graduating in 1978 are eligible.

Application forms and further particulars are available from the Secretary of the Institute. The closing date for applications is March 31, 1978. 1480(F)

WELSH PLANT BREEDING STATION

University College of Wales,
Aberystwyth
A.R.C. RESEARCH
STUDENTSHIP

Applications are invited for an A.R.C. Research Studentship tenable for three years from September October 1978 on one of the following research topics:

1. Sources of resistance to diterous stem borers in Italia and perennial ryegrass. (Supervisor: Mr J. A. Brook)
2. The basis of durable resistance to cereal mildew. (Supervisor: Dr T. L. Carver)
3. Sources and mechanisms of resistance to yellow rust in barley. (Supervisor: Dr B. C. Clifford)

The candidate, who should possess or expect to gain a good Honours degree in a relevant discipline, will be registered with the University of Wales for a higher degree.

Applications, including the names of two referees, should be sent before March 6, 1978 to The Secretary, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, Dyfed SY23 3EB from whom further particulars can be obtained. 1479(F)

THE WEST OF SCOTLAND AGRICULTURAL COLLEGE Crichton Royal Farm, Dumfries

RESEARCH STUDENTSHIP

Applications are invited for Research Studentship at the above experimental husbandry farm, to study herbage production and its utilisation by dairy cattle. The current value of the award, which will be tenable for up to three years, is £1,478 p.a. plus fees and approved travel expenses.

Applicants should have a first or second class honours degree in agriculture or agricultural science and the successful applicant will be required to register for a higher degree.

Further details may be obtained from the Secretary, The West of Scotland Agricultural College, Auchincruive Ayre KA6 5HW, with whom applications should be lodged by March 17, 1978. 1457(F)

UNIVERSITY OF ABERDEEN FACULTY OF MEDICINE RESEARCH STUDENTSHIPS

Applications are invited from recent first or upper second class honours graduates in a biological science subject, and from those who expect so to graduate in 1978, for research studentships established by the Faculty of Medicine from its Medical Endowment Funds. Successful applicants will study for the degree of Ph.D. on an approved subject in one of the Departments of Biochemistry, Developmental Biology, Pathology, Pharmacology or Physiology, commencing in October 1978.

The value of the studentship is £1,475 p.a. (for students living away from home) with payment of tuition fees and other allowances.

Application forms and further particulars of the projects may be obtained from D. K. Yule, University Office, Regent Walk, Aberdeen AB9 1FX, to whom applications should be submitted by March 17, 1978. 1468(F)

STUDENTSHIPS—continued

AWARD OF STUDENTSHIP
from October 1978

Applications are invited from graduates or persons with appropriate qualifications for the following postgraduate studentship, tenable from October 1978 at the stipend shown with remission of composition and student society fees:

Associated Lead Manufacturers Limited Studentship

for research in Chemistry, Physics or Metallurgy; £1,475 per annum; normally for three years. Further particulars and application forms may be obtained from the office of the Registrar to whom completed application form should be submitted by 2 June 1978. 1566(F)

EAST MALLING
RESEARCH STATION
AGRICULTURAL
RESEARCH COUNCIL
STUDENTSHIP

Postgraduate studentship tenable from October 1, 1978 for three years or research leading to higher degree in either:

(a) The role of phenolic glycosides in plant growth

or
(b) Earthworm populations in orchards as affected by soil management systems.

First or Upper-second Honours degree essential.

Further details and application form from Assistant to the Secretary, East Malling Research Station, Maidstone, Kent ME19 6BJ. 1528(F)

WYE COLLEGE
(University of London)
DEPARTMENT
OF HOP RESEARCH
AGRICULTURAL
RESEARCH COUNCIL
STUDENTSHIP

Applications are invited for a studentship tenable for three years, commencing October 1978, in the pathology Section of the Department. The research project will be on the application of mathematical methods to the dynamics of epidemic development. It will include experimental and analytical work on hop mildew diseases and the evaluation of quantitative methods in general.

Applicants should hold, or expect to hold, a first or upper second class honours degree in either biological science or mathematics. They need to combine aptitude in mathematical, statistical and computer techniques with a keen interest in their application to biological systems.

Application forms and further particulars may be obtained from the registrar, Wye College, Wye, Ashford, Kent TN25 5AH. 1565(F)

DUBLIN INSTITUTE FOR
ADVANCED STUDIES
SCHOOL OF
THEORETICAL PHYSICS

Applications are invited for research Scholarships tenable in the school during the academic year 1978-79. A limited number of stipends will be available. These awards are normally made at postdoctoral level. For further particulars and Forms of Application, candidates should apply immediately to The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Ireland. Completed applications should reach the Registrar not later than April 3, 1978. 1544(H)

FELLOWSHIPS

UNIVERSITY COLLEGE OF
NORTH WALES, BANGOR
SCHOOL OF PHYSICAL AND
MOLECULAR SCIENCES
POSTDOCTORAL
FELLOWSHIP IN
ORGANIC CHEMISTRY

Applications are invited for a Postdoctoral Fellowship funded by the I.C.T. Joint Research Scheme for work on the application of sulphur compounds.

The appointment, to the Research and Analogous Scale IA is within the range £3,761 to £4,190 per annum, and will be for a two-year period, commencing June 1, 1978, or such later date as may be arranged.

Applications, giving details of qualifications, research experience and the names and addresses of two referees, should be sent, as soon as possible, to the Assistant Registrar (Personnel), University College of North Wales, Bangor, Gwynedd LL57 2DG. 1501(E)

UNIVERSITY OF
WARWICK
RESEARCH FELLOWSHIP
IN VIROLOGY

Applications are invited for a Postdoctoral Fellowship in the Tumour Virus Research Group in the Department of Biological Sciences. The successful applicant will work in a small group studying the biochemistry of C type RNA tumour viruses, with particular reference to their ability to transform cells. Experience of nucleic acid technology, while not essential, would be an advantage.

Starting salary will be between points 1 and 6 on the Research Range IA scale: £3,333 to (£4,403) to £5,627 p.a. (under review). The Fellowship (funded by the Cancer Research Campaign) is available immediately and is renewable on an annual basis until September 1981.

Further details and application forms from the Academic Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No. 29/R/78. Closing date for receipt of applications is March 17, 1978. 1538(E)

IMPERIAL CANCER
RESEARCH FUND
RESEARCH FELLOWSHIP

Applications are invited for a Postdoctoral Research Fellow to work in area of surface antigens and receptors in normal and neoplastic epithelium with emphasis on application of S.E.M. marker probe procedures. Some experience in electron microscopy and immunochemistry or membrane biochemistry would be an advantage but not essential.

The appointment is tenable for two years with possible extension to three years and is available immediately.

Salary in range £3,678 to £4,698 (plus allowances) according to qualifications and experience.

Further information from Dr G. Hodges. Applications with curriculum vitae and names of two referees should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by March 17, 1978. 1476(E)

nature

Travelling Fellowships

Each year we have £1,500 available for travelling fellowships to be awarded to scientists or journalists who want to travel on *Nature's* behalf to parts of the world where we do not as yet have strong editorial contacts.

Sabbaticals

There are occasional opportunities for scientists to spend a period of a month or two in the *Nature* office working alongside our editorial staff.

We are at present inviting applicants for these positions for the coming year. Further details and application forms are available from The Editor, *Nature*, 4 Little Essex Street, London WC2. 1429(E)

Applications are invited for a

POSTDOCTORAL
RESEARCH FELLOWSHIP

for work on the mechanism of the photodynamic action of porphyrins in collaboration with Professor R. Bonnett and Professor I. A. Magnus. The position would suit an organic chemist or biochemist with an interest in photochemistry.

Initial salary in range £3,783 to £6,077 (including London Allowance). Please apply by letter, enclosing curriculum vitae and names and addresses of two referees, to Professor R. Bonnett, Department of Chemistry, Queen Mary College (University of London), Mile End Road, London E1 4NS. 1552(A)

RESEARCH FELLOWSHIP
Imperial Cancer Research Fund
Laboratories, Mill Hill, NW7

A postdoctoral Fellow is required to join a group working on the genetic and biochemical analysis of certain heat activated loci in *Drosophila melanogaster*, using cloned DNA fragments to investigate their organisation and expression.

Appointment will be for two years in the first instance with possible extension for a third year. Salary with entry according to qualifications and experience within range £4,649 to £5,669.

Further information from Dr D. Ish-Horowicz (01-959 3236). Applications with curriculum vitae and names of two referees, should be sent to The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX by March 17, 1978. 1475(E)

THE UNIVERSITY OF
BRITISH COLUMBIA
DEPARTMENT OF
CHEMISTRY
GRADUATE TEACHING
ASSISTANTSHIPS

Graduate Teaching Assistantships are available for candidates with high academic records who wish to pursue further studies towards the M.Sc. and Ph.D. degrees in chemistry. Excellent research facilities are available in all areas of modern chemical science, ranging from bioinorganic chemistry to chemical physics. The minimum stipends including summer research assistantship will be \$6,120.00 per annum for first year and \$6,500.00 for students entering with a Master's Degree. The stipends are currently under review. In addition, many special merit awards are made to those Graduate Teaching Assistants who show excellence in the performance of their duties. Numerous graduate scholarships are also available for students with outstanding academic records.

Application forms and further particulars may be obtained from the undersigned:

Professor C. A. McDowell,
Department of Chemistry,
The University of
British Columbia,
Canada V6T 1W5

THE UNIVERSITY
OF SHEFFIELD
POSTGRADUATE COURSE
IN SOLID STATE PHYSICS

The course is designed for post-graduate students who wish to obtain a more advanced background knowledge and further practical training in solid state physics; it will last for one academic year, October to July, ending in an examination for the degree of M.Sc.

Electron states in crystals
Lattice dynamics and related properties.
Determination of the structure of solids
Preparation of materials
Physical properties of solids
Magnetism in solids
Physics of semiconductor materials
Solid state devices
This course has been accepted under the S.R.C. Advanced Course Studentship Scheme.

Further details may be obtained from the Administrative Secretary, Department of Physics, The University, Sheffield S3 7RH. 1508(D)

SYMPOSIUMS

SYMPOSIUM ON 'THEORY AND PRACTICE IN AFFINITY TECHNIQUES'. FOR INFORMATION SEE NATURE, PAGE XXIV, FEBRUARY 16, 1978. 1490(M)

VITELLOGENIN
WORKSHOP

to be held in BORGER (near GRONINGEN), The Netherlands, September 25, 26 and 27, 1978.

Sponsored by

European Molecular Biology
Organisation (E.M.B.O.)

and

University of Groningen,
Fonger de Haan Fund,
The Netherlands.

The aim of the workshop is to discuss recent advances and future directions of research on the hormonal regulation of vitellogenin synthesis in vertebrates and insects.

There will be no registration fee and the costs of accommodation and meals will be covered by the organisers. Travel expenses can be partially reimbursed if necessary. Maximally 50 participants will be admitted and selection will be based on their present research interests.

Further information and application forms may be obtained from Professor Dr M. Gruber, Biochemisch Laboratorium, The University, Zernikelaan, Groningen, The Netherlands.

Closing date for applications:
April 15, 1978. 1494(M)

COURSES

UNIVERSITY
OF EDINBURGH

M.Sc.
IN NEUROPHYSIOLOGY

The one-year course of full-time study is open to graduates in Medicine, Veterinary Medicine or Science and provides an opportunity to post-graduate students to deepen their knowledge of the ideas and techniques fundamental to neurophysiology.

Advanced Course Studentships may be available for the Session 1978-79.

For further details please write to:
Dr A. G. Brown
Department of Veterinary Physiology
University of Edinburgh
Edinburgh EH9 1QH 1547(D)

QUEEN MARY COLLEGE
(University of London)

PART-TIME
M.Sc. COURSE
IN GENETICS

Applications are invited for a part-time M.Sc. Course in Genetics beginning October 1978. Most aspects of genetics will be covered and the course is designed particularly for individuals in full-time employment in education, industry or medicine.

Applicants should normally possess a good honours degree in Biology or a related discipline. Further details and application forms can be obtained from the Deputy Registrar, Queen Mary College (University of London), Mile End Road, London E1 4NS. 1516(D)

Under the sponsorship of the European Communities, the "Centro di Biologia Molecolare del Consiglio nazionale delle Ricerche (CNR)" is organising a interdisciplinary training course, to take place in Rome from September 18 to 30, 1978 on:

**A MOLECULAR APPROACH TO THE BIOLOGY
OF RED BLOOD CELLS**

The aim of the course is to investigate by advanced physico-chemical techniques various molecular aspects of red blood cell biology. Qualified to participate in the course are young scientists with a good physico-chemical and/or biochemical background, both theoretical and practical.

The course will consist of lectures and of practical laboratory exercises on the following subjects:

- A. Molecular biology of single constituents of red blood cells.
 - I. Hemoglobin and isolated hemoglobin chains
 - (1) Interaction with ligands: equilibrium and kinetics (rapid mixing and relaxation techniques)
 - (2) Interaction with heterotropic allosteric effectors
 - (3) Abnormal hemoglobins.
 - II. Enzymes of the red blood cell involved in oxidative pathways and in the scavenging of high reactive oxygen derivatives.
 - III. The red blood cell membrane: structure, permeability, transport and membrane-associated proteins.
- B. The red blood cell as an integrated system.
 - (1) Oxygen binding by whole erythrocytes system
 - (2) Autoxidation phenomena
 - (3) Regulation of glucose metabolism
 - (4) Ageing and hemolysis.
- C. Hemoglobin biosynthesis and its regulation at the molecular level.

The working language of the course will be English.

Applications for enrolment should reach the Molecular Biology and Radiobiology Course Secretariat, Commission of the European Communities DG XII, rue de la Loi 200, B-1049 Brussels, before 20 March 1978, and be accompanied by the applicant's personal history (stating knowledge of languages), a list of his scientific publications and a letter from the head of his laboratory.

Further information may be obtained from the same address.

SCIENTIFIC INSTRUMENTS LABORATORY EQUIPMENT

MINI-ADS

SINGER MICROMANIPULATORS ARE FAMOUS BECAUSE

Singer Micromanipulators enable anyone to make exact movements without tremor or lost motion, in three dimensions, using a single control handle under low or high power magnification.

A varied range available. All simple to operate.

How Britain runs its science

This highly successful chart, which appeared in *Nature* 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2' x 3' and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US \$1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance

Synthetic Lecithins

Highly purified for membrane and phospholipase hydrolysis studies. All available from stock.

	Cat. No.	25 mg
Dicaprylyl-L- α -Lecithin	6627	\$27.50
Dicapryl-L- α -Lecithin	6629	27.50
Dilauroyl-L- α -Lecithin	6631	27.50
Dimyristoyl-L- α -Lecithin	6633	27.50
Dipalmitoyl-L- α -Lecithin	6604	27.50
Distearoyl-L- α -Lecithin	6606	27.50
Dioleoyl-L- α -Lecithin	6602	35.00
Dilinoleoyl-L- α -Lecithin	6610	38.50
Diarachidonyl-L- α -Lecithin	6608	65.00

We also offer a wide variety of pure natural lecithins.

A CHANGE IN MIND

A MEDICAL TRILOGY FROM YORKSHIRE TELEVISION
Three documentaries from Yorkshire Television's science unit which will reflect changing attitudes to the mind in the fields of neurology, psychiatry and psychology.

This week A CRISIS IN THE FAMILY

A report on...

How a group of psychiatrists are dramatically challenging our ideas of mental illness. Their belief is that admission to hospital is no cure for mental illness. Every day, round the clock, a team of psychiatrists and social workers is available to respond to the call to someone suffering serious emotional problems. This is the Crisis Intervention Scheme at Napsbury Hospital, near St. Albans. Their aim, above all, is to keep that person out of hospital.
